*Stresses above those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. This is a stress rating only and functional operation of the device at these or any other conditions above those listed in the operational sections of this specification is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

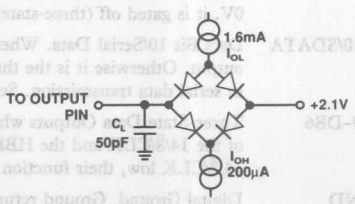

Figure 1. Load Circuit for Access Time

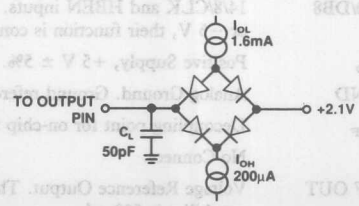

Figure 2. Load Circuit for Output Float Delay

CAUTION

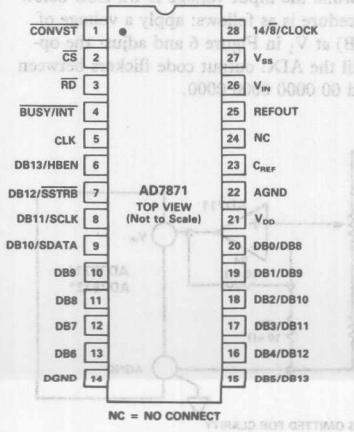
ESD (electrostatic discharge) sensitive device. The digital control inputs are diode protected; however, permanent damage may occur on unconnected devices subject to high energy electrostatic fields. Unused devices must be stored in conductive foam or shunts. The protective foam should be discharged to the destination socket before devices are inserted.

AD7871 PIN FUNCTION DESCRIPTION

DIP No.	Mnemonic	Function
1	$\overline{\text{CONVST}}$	Convert Start. A low to high transition on this input puts the track/hold into the hold mode. This input is asynchronous to the CLK. $\overline{\text{CS}}$ and $\overline{\text{RD}}$ must be held high for the duration of this pulse.
2	$\overline{\text{CS}}$	Chip Select. Active low logic input. The device is selected when this input is active. With $\overline{\text{CONVST}}$ tied low, a new conversion is initiated when $\overline{\text{CS}}$ goes low.
3	$\overline{\text{RD}}$	Read. Active low logic input. This input is used in conjunction with $\overline{\text{CS}}$ low to enable the data outputs.
4	BUSY/INT	Busy/Interrupt. Logic low output indicating converter status. See timing diagrams.
5	CLK	Clock Input. An external TTL-compatible clock may be applied to this input. Alternatively, tying this pin to V_{SS} enables the internal laser-trimmed oscillator.
6	DB13/HBEN	Data Bit 13 (MSB)/High Byte Enable. The function of this pin is dependent on the state of the 14/$\overline{8}$/CLK input (see Pin 28). When 14-bit data is selected, this pin provides the DB13 output. When either byte or serial data is selected, this pin becomes the HBEN logic input. HBEN is used for 8-bit bus interfacing. When HBEN is low, DB7 to DB0 is the lower byte of data. With HBEN high, DB7 to DB0 is the upper byte of data (see Table I).

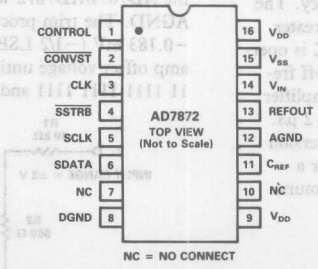
HBEN	DB7	DB6	DB5	DB4	DB3	DB2	DB1	DB0
HIGH	LOW	LOW	DB13	DB12	DB11	DB10	DB9	DB8
LOW	DB7	DB6	DB5	DB4	DB3	DB2	DB1	DB0

Table I. Byte Output Format



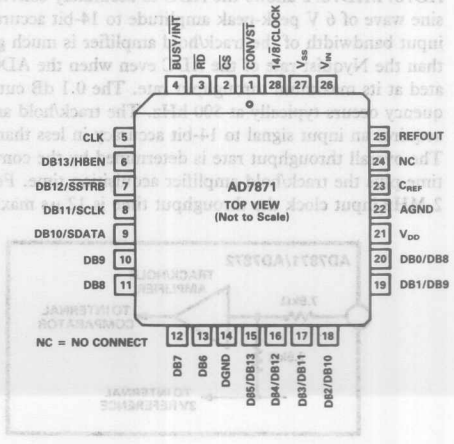
7	DB12/$\overline{\text{SSTRB}}$	Data Bit 12/Serial Strobe. When 14-bit data is selected, this pin provides the DB12 data output. Otherwise it is an active low three-state output which provides a framing pulse for serial data.
8	DB11/SCLK	Data Bit 11/Serial Clock. When 14-bit data is selected, this pin provides the DB11 data output. Otherwise SCLK is the gated serial clock output which is derived from the internal or external ADC clock. If the 14/$\overline{8}$/CLK input is held at −5 V, then the SCLK runs continuously. With 14/$\overline{8}$/CLK at 0V, it is gated off (three-state) after serial transmission is complete.
9	DB10/SDATA	Data Bit 10/Serial Data. When 14-bit parallel data is selected, this pin provides the DB10 data output. Otherwise it is the three-state serial data output used in conjunction with SCLK and $\overline{\text{SSTRB}}$ in serial data transmission. Serial data is valid on the falling edge of SCLK, when $\overline{\text{SSTRB}}$ is low.
10–13	DB9–DB6	Three-State Data Outputs which are controlled by $\overline{\text{CS}}$ and $\overline{\text{RD}}$. Their function depends on the state of the 14/$\overline{8}$/CLK and the HBEN inputs. With 14/$\overline{8}$/CLK high, they are always DB9–DB6. With 14/$\overline{8}$/CLK low, their function depends on HBEN (see Table I).
14	DGND	Digital Ground. Ground return for digital circuitry.
15–20	DB5/DB13–DB0/DB8	Three-State Data Outputs which are controlled by $\overline{\text{CS}}$ and $\overline{\text{RD}}$. Their function depends on the 14/$\overline{8}$/CLK and HBEN inputs. With 14/$\overline{8}$/CLK high, they are always DB5–DB0. With 14/$\overline{8}$/CLK low or −5 V, their function is controlled by HBEN (see Table I).
21	V_{DD}	Positive Supply, +5 V ± 5%.
22	AGND	Analog Ground. Ground reference for analog circuitry.
23	C_{REF}	Decoupling point for on-chip reference. Connect 10 nF between this pin and AGND.
24	NC	No Connect.
25	REF OUT	Voltage Reference Output. The internal 3 V reference is provided at this pin. The external load capability is 500 μA.
26	V_{IN}	Analog Input. The input range is ±3 V.
27	V_{SS}	Negative Supply, −5 V ± 5%.
28	14/$\overline{8}$/CLK	Three-Function Input. Defines both the parallel and serial data formats. With this pin at +5 V, the output data is 14-bit parallel only. With this pin at 0 V, both byte and serial data are available, and the SCLK is noncontinuous. With this pin at −5 V, both byte and serial data are available and the SCLK is continuous.

AD7872 PIN FUNCTION DESCRIPTION



DIP No.	Mnemonic	Function
1	CONTROL	Control Input. With this pin at 0 V, the SCLK is noncontinuous. With this pin at −5 V, the SCLK is continuous.
2	$\overline{\text{CONVST}}$	Convert Start. A low to high transition on this input puts the track/hold into the hold mode. This input is asynchronous to the CLK.
3	CLK	Clock Input. An external TTL-compatible clock may be applied to this input. Alternatively, tying this pin to V_{SS}, enables the internal laser-trimmed oscillator.
4	$\overline{\text{SSTRB}}$	This is an active low three-state output which provides a framing pulse for serial data. An external 4.7 kΩ pull-up resistor is required on $\overline{\text{SSTRB}}$.
5	SCLK	Serial Clock. SCLK is the gated serial clock output which is derived from the internal or external ADC clock. If the 14/$\overline{8}$/CLK input is at −5 V, then the SCLK runs continuously. With CONTROL at 0 V, it is gated off (three-state) after serial transmission is complete. SCLK is an open-drain output and requires an external 2 kΩ pull-up resistor.
6	SDATA	Serial Data. This is the three-state serial data output used in conjunction with SCLK and $\overline{\text{SSTRB}}$ in serial data transmission. Serial data is valid on the falling edge of SCLK, when $\overline{\text{SSTRB}}$ is low. An external 4.7 kΩ pull-up resistor is required on SDATA.
7	NC	No Connect.
8	DGND	Digital Ground. Ground return for digital circuitry.
9	V_{DD}	Positive Supply for analog circuitry, +5 V ± 5%.
10	NC	No Connect.
11	C_{REF}	Decoupling point for on-chip reference. Connect 10 nF capacitor between this pin and AGND.
12	AGND	Analog Ground. Ground reference for analog circuitry.
13	REF OUT	Voltage Reference Output. The internal 3 V reference is provided at this pin. The external load capability is 500 μA.
14	V_{IN}	Analog Input. The input range is ±3 V.
15	V_{SS}	Negative Supply, −5 V ± 5%.
16	V_{DD}	Positive Supply for analog circuitry, +5 V ± 5%. Pin 16 and Pin 9 should be connected together.

PIN CONFIGURATIONS



DIP

DIP, SOIC

PLCC

approximation ADC based on a fast settling voltage-output DAC, a high speed comparator and CMOS SAR, a track/hold amplifier, a 3 V buried Zener reference, a clock oscillator and control logic.

INTERNAL REFERENCE

The AD7871/AD7872 has an on-chip temperature compensated buried Zener reference which is factory trimmed to 3 V ± 10 mV. Internally it provides both the DAC reference and the dc bias required for bipolar operation. Reference noise is minimized by connecting a capacitor between C_{REF} and AGND. For specified operation this capacitor should be 10 nF. The reference output is available (REF OUT) and is capable of providing up to 500 μA to an external load.

The maximum recommended capacitance on REF OUT for normal operation is 50 pF. If the reference is required for use external to the AD7871/AD7872, it should be decoupled with a 200 Ω resistor in series with a parallel combination of a 10 μF tantalum capacitor and a 0.1 μF ceramic capacitor. These decoupling components are required to remove voltage spikes caused by the AD7871/AD7872's internal operation.

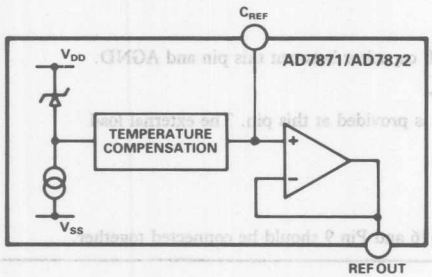


Figure 3. AD7871/AD7872 Reference Circuit

TRACK-AND-HOLD AMPLIFIER

The track-and-hold amplifier on the analog input of the AD7871/AD7872 allows the ADC to accurately convert an input sine wave of 6 V peak-peak amplitude to 14-bit accuracy. The input bandwidth of the track/hold amplifier is much greater than the Nyquist rate of the ADC even when the ADC is operated at its maximum throughput rate. The 0.1 dB cutoff frequency occurs typically at 500 kHz. The track/hold amplifier acquires an input signal to 14-bit accuracy in less than 2 μs. The overall throughput rate is determined by the conversion time plus the track/hold amplifier acquisition time. For a 2 MHz input clock the throughput time is 12 μs maximum.

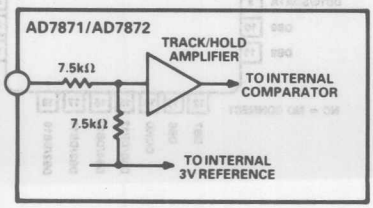

Figure 4. AD7871/AD7872 Analog Input

CONVST input is used to start conversion, then the track to hold transition occurs on the rising edge of $\overline{CONVST}$. If $\overline{CS}$ on the AD7871 starts conversion, this transition occurs on the falling edge of $\overline{CS}$.

ANALOG INPUT

Figure 4 shows the AD7871/AD7872 analog input. The analog input range is ±3 V into an input resistance of typically 15 kΩ. The designed code transitions occur midway between successive integer LSB values (i.e., 1/2 LSB, 3/2 LSBs, 5/2 LSBs . . . FS −3/2 LSBs). The output code is 2s complement binary with 1 LSB = FS/16384 = 6 V/16384 = 366 μV. The ideal input/output transfer function is shown in Figure 5.

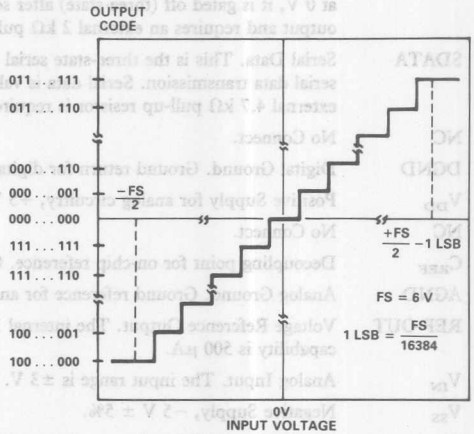

Figure 5. Bipolar Input/Output Transfer Function

BIPOLAR OFFSET AND FULL-SCALE ADJUSTMENT

When the AD7871/AD7872's offset and full-scale errors need to be adjusted, offset error must be adjusted first. This is achieved by trimming the offset of the op amp driving the analog input of the AD7871/AD7872 while the input voltage is 1/2 LSB below AGND. The trim procedure is as follows: apply a voltage of −0.183 mV (−1/2 LSB) at V_1 in Figure 6 and adjust the op-amp offset voltage until the ADC output code flickers between 11 1111 1111 1111 and 00 0000 0000 0000.

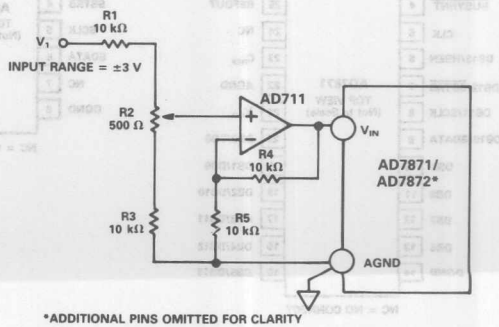

Figure 6. Bipolar Adjust Circuit

Gain error can be adjusted at either the first code transition (ADC negative full scale) or the last code transition (ADC positive full scale). The trim procedures for both cases are as follows (see Figure 6).

Positive Full-Scale Adjust

Apply a voltage of 2.9995 V (FS/2 −3/2 LSBs) at V_1 and adjust R2 until the ADC output code flickers between 01 1111 1111 1110 and 01 1111 1111 1111.

Negative Full-Scale Adjust

Apply a voltage of −2.9998 V (−FS/2+1/2 LSB) at V_1 and adjust R2 until the ADC output code flickers between 10 0000 0000 0000 and 10 0000 0000 0001.

UNIPOLAR OPERATION

A typical unipolar circuit is shown in Figure 7. The AD7871/AD7872 REF OUT is used to offset the analog input by 3 V. The analog input range is determined by the ratio of R3 to R4. The minimum range with which the circuit will work is 0 to +3 V. The resistor values are given in Figure 7 for input ranges of 0 to +5 V and 0 to +10 V. R5 and R6 are included for offset and full scale adjust only and should be omitted if adjustment is not required.

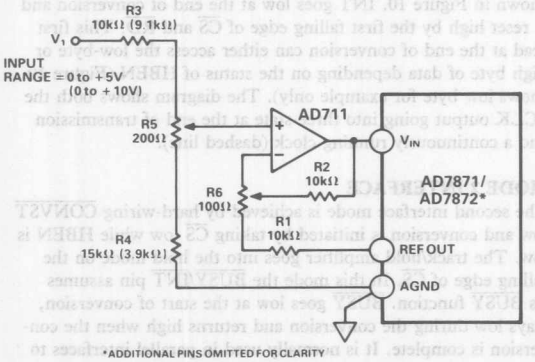

Figure 7. AD7871/AD7872 Unipolar Circuit

The ideal input/output transfer function is shown in Figure 8. The output can be converted to straight binary by inverting the MSB.

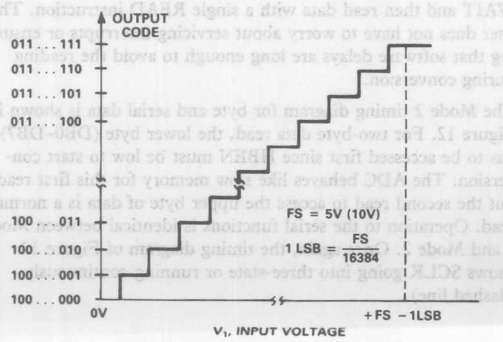

Figure 8. Unipolar Transfer Function

UNIPOLAR OFFSET AND FULL-SCALE ADJUSTMENT

When absolute accuracy is required, offset and full-scale error can be adjusted to zero. Offset must be adjusted before full-scale. This is achieved by applying an input voltage of (1/2 LSB) to V_1 and adjust R6 until the ADC output code flickers between 10 0000 0000 0000 and 10 0000 0000 0001. For full-scale adjustment apply an input voltage of (FS −3/2 LSBs) to V_1 and adjust R5 until the output code flickers between 01 1111 1111 1110 and 01 1111 1111 1111.

TIMING AND CONTROL

The conversion time for both external and internal clock can vary from 19 to 20 rising clock edges depending on the conversion start to ADC clock synchronization. If a conversion is initiated within 30 ns prior to a rising edge of the ADC clock, the conversion time will consist of 20 rising clock edges.

There are two basic operating modes for the AD7871. In the first mode (Mode 1) the $\overline{\text{CONVST}}$ line is used to start conversion and drive the track/hold into its hold mode. At the end of conversion, the track/hold returns to its tracking mode. It is intended principally for digital signal processing and other applications where precise sampling in time is required. In these applications, it is important that the signal sampling occurs at exactly equal intervals to minimize errors due to sampling uncertainty or jitter. For these cases, the $\overline{\text{CONVST}}$ line is driven by a timer or some precise clock source.

The second mode is achieved by hard-wiring the $\overline{\text{CONVST}}$ line low. This mode (Mode 2) is intended for use in systems where the microprocessor has total control of the ADC, both initiating the conversion and reading the data. $\overline{\text{CS}}$ and $\overline{\text{RD}}$ start conversion, and the microprocessor will normally be driven into a WAIT state for the duration of conversion by $\overline{\text{BUSY/INT}}$.

The AD7872 has one operating mode only. This is Mode 1, described above, which uses $\overline{\text{CONVST}}$ to start conversion.

DATA OUTPUT FORMATS

The AD7871 offers a choice of three data output formats, one serial and two parallel. The parallel data formats include a single 14-bit parallel word for 16-bit data buses and a two-byte format for 8-bit data buses. The data format is controlled by the 14/$\overline{8}$/CLK input. A logic high on this pin selects the 14-bit parallel output format only. A logic low or −5 V applied to this pin allows the user access to either serial or byte formatted data. Three of the pins previously assigned to the four MSBs in parallel form are now used for serial communications while the fourth pin becomes a control input for the byte-formatted data. The three possible data output formats can be selected in either of the modes of operation.

The AD7872 is a serial output device only. The serial data format is exactly the same as the AD7871.

Parallel Output Format

The two parallel formats available on the AD7871 are a 14-bit wide data word and a two-byte data word. In the first, all 14 bits of data are available at the same time on DB13 (MSB) through DB0 (LSB). In the second, two reads are required to access the data. When this data format is selected, the DB13/HBEN pin assumes the HBEN function. HBEN selects which byte of data is to be read from the AD7871. When HBEN is low, the lower 8 bits of data are placed on the data bus during a read operation; with HBEN high, the upper 6 bits

of the 14-bit word are placed on the data bus. These 6 bits are right justified and thereby occupy the lower six bits of the byte while the upper two bits are zeros.

Serial Output Format

Serial data is available on the AD7871 when the 14/$\overline{8}$/CLK input is at 0 V or −5 V and in this case the DB12/$\overline{\text{SSTRB}}$, DB11/SCLK and DB10/SDATA pins assume their serial functions. The AD7872 is a serial output device only. The serial function on both devices is identical. Serial data is available during conversion with a word length of 16 bits; 2 leading zeros, followed by the 14-bit conversion result starting with the MSB. The data is synchronized to the serial clock output (SCLK) and is framed by the serial strobe ($\overline{\text{SSTRB}}$). Data is clocked out on a low to high transition of the serial clock and is valid on the falling edge of this clock while the $\overline{\text{SSTRB}}$ output is low. $\overline{\text{SSTRB}}$ goes low at the start of conversion and the first serial data bit (which is the first leading zero) is valid on the first falling edge of SCLK. All the serial lines are open-drain outputs and require external pull-up resistors.

The serial clock out is derived from the ADC master clock source which may be internal or external. Normally, SCLK is required during the serial transmission only. In these cases it can be shut down (i.e., placed into three-state) at the end of conversion to allow multiple ADCs to share a common serial bus. However, some serial systems (e.g., TMS32020) require a serial clock which runs continuously. Both options are available on the AD7871 and AD7872. With the 14/$\overline{8}$/CLK input on the AD7871 at −5 V, the serial clock (SCLK) runs continuously; when 14/$\overline{8}$/CLK is at 0 V, SCLK goes into three-state at the end of transmission. The CONTROL pin on the AD7872 performs the same function. When this is at 0 V, SCLK is noncontinuous and when it is at −5 V, SCLK is continuous.

The SCLK, SDATA and $\overline{\text{SSTRB}}$ lines are open-drain outputs. If these are required to drive capacitive loads in excess of 35 pF, buffering is recommended.

MODE 1 INTERFACE

Conversion is initiated by a low going pulse on the $\overline{\text{CONVST}}$ input. The rising edge of this $\overline{\text{CONVST}}$ pulse starts conversion and drives the track/hold amplifier into its hold mode. The $\overline{\text{BUSY}}$/$\overline{\text{INT}}$ status output assumes its $\overline{\text{INT}}$ function in this mode. $\overline{\text{INT}}$ is normally high and goes low at the end of conversion. This $\overline{\text{INT}}$ line can be used to interrupt the microprocessor. A read operation to the AD7871 accesses the data and the $\overline{\text{INT}}$ line is reset high on the falling edge of $\overline{\text{CS}}$ and $\overline{\text{RD}}$. The $\overline{\text{CONVST}}$ input must be high when $\overline{\text{CS}}$ and $\overline{\text{RD}}$ are brought low for the AD7871 to operate correctly in this mode. It is important, especially in systems where the conversion start ($\overline{\text{CONVST}}$) pulse is asynchronous to the microprocessor, to ensure that a parallel or byte data read is not attempted during a conversion. Trying to read data during a conversion can cause errors to the conversion in progress. Avoid pulsing the $\overline{\text{CONVST}}$ line a second time before conversion end since it can cause errors in the conversion result. In applications where precise sampling is not critical, the $\overline{\text{CONVST}}$ pulse can be generated from microprocessor $\overline{\text{WR}}$ line OR-gated with the AD7871 $\overline{\text{CS}}$ input. In some applications, depending on power supply turn-on time, the AD7871/AD7872 may perform a conversion on power-up. In this case, the $\overline{\text{INT}}$ line on the AD7871 will power up low, and a dummy read to the device will be required to reset the $\overline{\text{INT}}$ line before starting conversion.

Figure 9 shows the Mode 1 timing diagram for a 14-bit parallel data output format (14/$\overline{8}$/CLK = +5 V). A read to the AD7871 at the end of conversion accesses all 14 bits of data at the same time. Serial data is not available for this data output format.

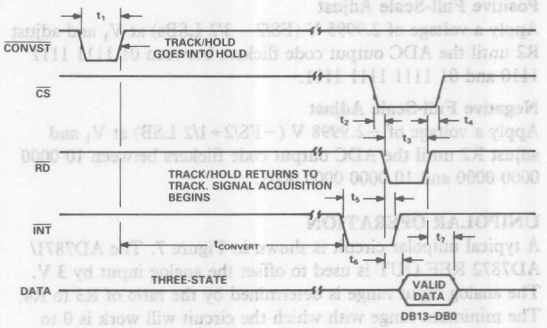

Figure 9. Mode 1 Timing Diagram, 14-Bit Parallel Read

The Mode 1 function timing diagram for byte and serial data is shown in Figure 10. $\overline{\text{INT}}$ goes low at the end of conversion and is reset high by the first falling edge of $\overline{\text{CS}}$ and $\overline{\text{RD}}$. This first read at the end of conversion can either access the low-byte or high byte of data depending on the status of HBEN (Figure 10 shows low byte for example only). The diagram shows both the SCLK output going into three-state at the end of transmission and a continuously running clock (dashed line).

MODE 2 INTERFACE

The second interface mode is achieved by hard-wiring $\overline{\text{CONVST}}$ low and conversion is initiated by taking $\overline{\text{CS}}$ low while HBEN is low. The track/hold amplifier goes into the hold mode on the falling edge of $\overline{\text{CS}}$. In this mode the $\overline{\text{BUSY}}$/$\overline{\text{INT}}$ pin assumes its $\overline{\text{BUSY}}$ function. $\overline{\text{BUSY}}$ goes low at the start of conversion, stays low during the conversion and returns high when the conversion is complete. It is normally used in parallel interfaces to drive the microprocessor into a WAIT state for the duration of conversion.

Figure 11 shows the Mode 2 timing diagram for the 14-bit parallel data output format (14/$\overline{8}$/CLK = +5 V). In this case the ADC behaves like slow memory. The major advantage of this interface is that it allows the microprocessor to start conversion, WAIT and then read data with a single READ instruction. The user does not have to worry about servicing interrupts or ensuring that software delays are long enough to avoid the reading during conversion.

The Mode 2 timing diagram for byte and serial data is shown in Figure 12. For two-byte data read, the lower byte (DB0–DB7) has to be accessed first since HBEN must be low to start conversion. The ADC behaves like slow memory for this first read, but the second read to access the upper byte of data is a normal read. Operation to the serial functions is identical between Mode 1 and Mode 2. Once again, the timing diagram of Figure 12 shows SCLK going into three-state or running continuously (dashed line).

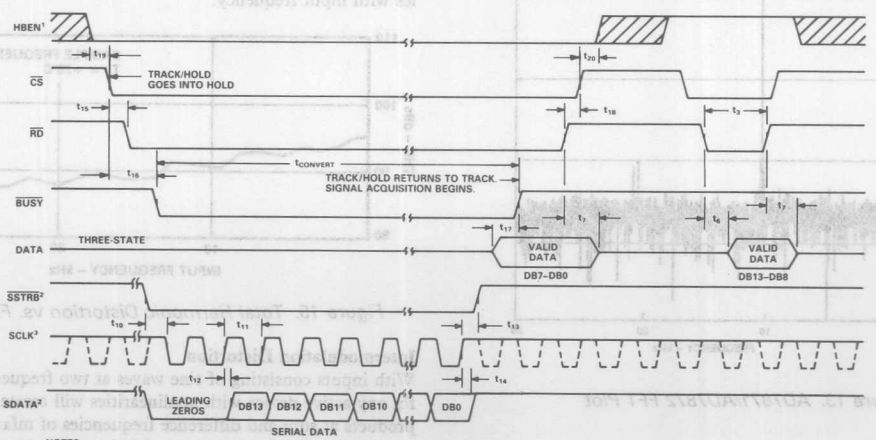

Figure 12. Mode 2 Timing Diagram, Byte or Serial Read

DYNAMIC SPECIFICATIONS

The AD7871/AD7872 is specified and tested for dynamic performance specifications as well as traditional dc specifications such as Integral and Differential Nonlinearity. These ac specifications are required for the signal processing applications such as Speech Recognition, Spectrum Analysis, and High Speed Modems. These applications require information on the effects on the spectral content of the input signal. Hence, the parameters for which the AD7871/AD7872 is specified include SNR, Harmonic Distortion, Intermodulation Distortion and Peak Harmonics. These terms are discussed in more detail in the following sections.

Signal-to-Noise Ratio (SNR)

SNR is the measured signal to noise ratio at the output of the ADC. The signal is the rms magnitude of the fundamental. Noise is the rms sum of all the nonfundamental signals up to half the sampling frequency (fs/2) excluding dc. SNR is dependent upon the number of quantization levels used in the digitization process; the more levels, the smaller the quantization noise. The theoretical signal to noise ratio for a sine wave input is given by:

$$SNR(dB) = (6.02N + 1.76) \quad (1)$$

where N is the number of bits in the ADC. Thus for an ideal 14-bit converter, SNR = 86 dB.

The output spectrum from the ADC is evaluated by applying a sine wave signal of very low distortion to the V_{IN} input which is sampled at an 83 kHz sampling rate. A Fast Fourier Transform (FFT) plot is generated from which the SNR data can be obtained. Figure 13 shows a typical 2048 point FFT plot of the AD7871/AD7872 with an input signal of 10 kHz and a sampling frequency of 83 kHz. The SNR obtained from this graph is 80 dB. It should be noted that the harmonics are included when calculating the SNR.

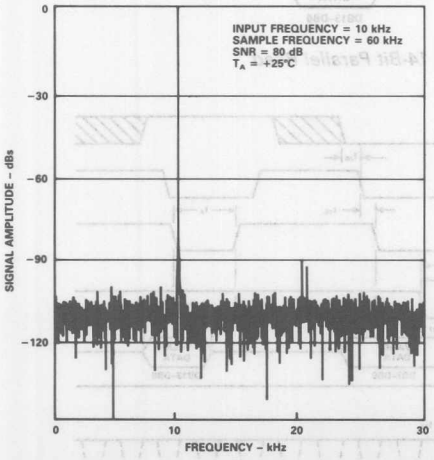

Figure 13. AD7871/AD7872 FFT Plot

Effective Number of Bits

The formula given in Equation 1 relates the SNR to the number of bits. Rewriting the formula, as in Equation 2, it is possible to get a measure of performance expressed in effective number of bits (N).

$$N = \frac{SNR - 1.76}{6.02} \quad (2)$$

The effective number of bits for a device can be calculated directly from its measured SNR. Figure 14 shows a typical plot of effective number of bits versus frequency for the AD7871/AD7872 with a sampling frequency of 60 kHz.

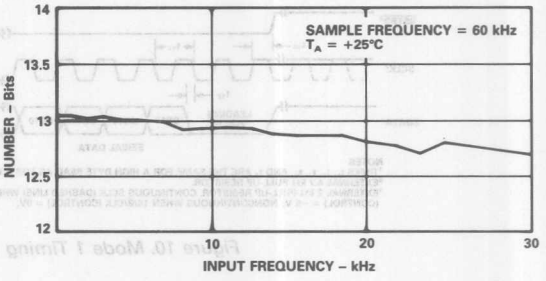

Figure 14. Effective Number of Bits vs. Frequency

Harmonic Distortion

Harmonic Distortion is the ratio of the rms sum of harmonics to the fundamental. For the AD7871/AD7872, Total Harmonic Distortion (THD) is defined as

$$THD(dB) = 20 \log \frac{\sqrt{V_2^2 + V_3^2 + V_4^2 + V_5^2 + V_6^2}}{V_1}$$

where V_1 is the rms amplitude of the fundamental and V_2, V_3, V_4, V_5 and V_6 are the rms amplitudes of the second through the sixth harmonic. The THD is also derived from the FFT plot of the ADC output spectrum. Figure 15 shows how the THD varies with input frequency.

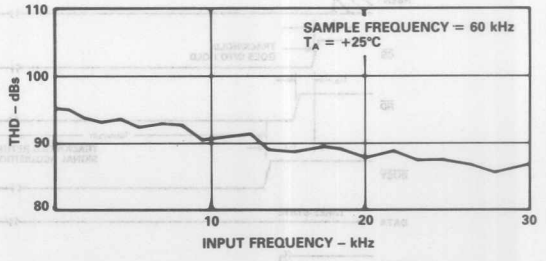

Figure 15. Total Harmonic Distortion vs. Frequency

Intermodulation Distortion

With inputs consisting of sine waves at two frequencies, fa and fb, any active device with nonlinearities will create distortion products at sum and difference frequencies of mfa±nfb where m, n = 0, 1, 2, 3, etc. Intermodulation terms are those for which neither m or n are equal to zero. For example, the second order terms include (fa+fb) and (fa−fb), while the third order terms include (2fa+fb), (2fa−fb), (fa+2fb) and (fa−2fb).

Using the CCIF standard where two input frequencies near the top end of the input bandwidth are used, the second and third order terms are of different significance. The second order terms are usually distanced in frequency from the original sine waves while the third order terms are usually at a frequency close to the input frequencies. As a result, the second and third order terms are specified separately. The calculation of the intermodulation distortion is as per the THD specification where it is the ratio of the rms sum of the individual distortion products to the rms amplitude of the fundamental expressed in dBs. In this case, the input consists of two, equal amplitude, low distortion sine waves. Figure 16 shows a typical IMD plot for the AD7871/AD7872.

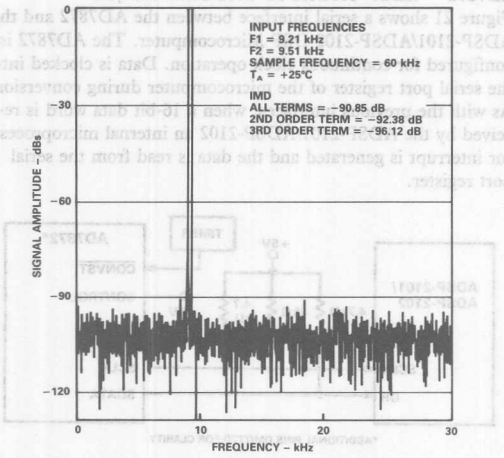

Figure 16. AD7871/AD7872 IMD Plot

Peak Harmonic or Spurious Noise

Peak Harmonic or Spurious Noise is defined as the ratio of the rms value of the next largest component in the ADC output spectrum (up to fs/2 and excluding dc) to the rms value of the fundamental. Normally, the value of this specification will be determined by the largest harmonic in the spectrum, but for parts where the harmonics are buried in the noise floor peak will be a noise peak.

MICROPROCESSOR INTERFACE

The AD7871 and AD7872 have a wide variety of interfacing options. The AD7871 offers two operating modes and three data-output formats, while the AD7872 is a dedicated serial output device. The fast data access times on the parallel modes of the AD7871 allow interfacing to the very fast DSPs. The serial mode on both the AD7871 and AD7872 is compatible with the serial port structures on all the popular DSPs.

Parallel Read Interfacing

Figures 17 and 18 show interfaces to the ADSP-2100 and the TMS32020/C25 DSP processors. The AD7871 is operating in Mode 1, parallel read for both interfaces. An external timer controls conversion start asynchronously to the microprocessor. At the end of each conversion the ADC $\overline{\text{BUSY/INT}}$ interrupts the microprocessor and the conversion result is read from the ADC with the following instruction:

ADSP-2100 MR0 = DM(ADC)

TMS32020/C25: IN D,ADC

MR0 = ADSP-2100 MR0 Register

D = Data Memory Address

ADC = AD7871 Address

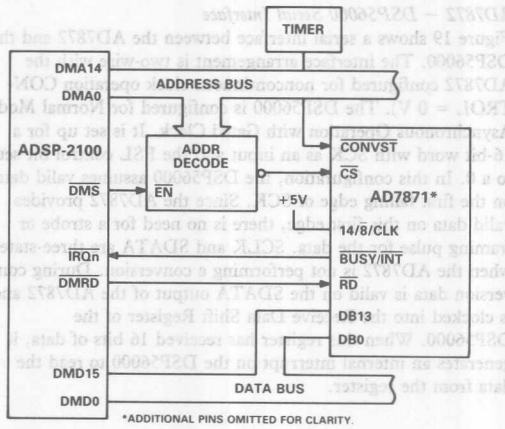

Figure 17. AD7871 to ADSP-2100 Parallel Interface

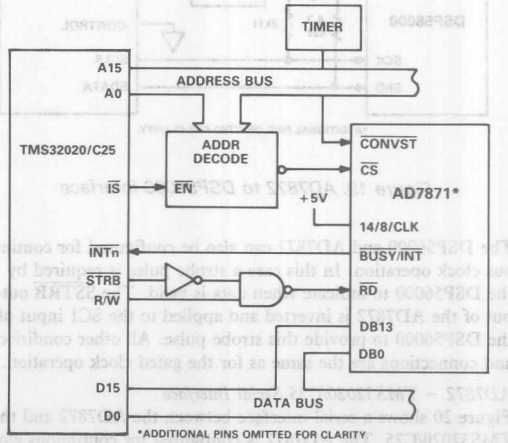

Figure 18. AD7871 to TMS32020/C25 Interface

Some applications may require that conversions be initiated by the microprocessor rather than an external timer. One option is to decode the AD7871 $\overline{\text{CONVST}}$ from the address bus so that a write operation to the ADC starts a conversion. Data is read at the end of conversion as described earlier. Note, a read operation must not be attempted during conversion.

face. The diagrams that follow show the AD7872 interfaces only but the AD7871 could just as easily be used in these circuits. Figures 19, 20 and 21 show the AD7872 connected to three popular DSPs. In all three interfaces, $\overline{\text{CONVST}}$ is used to start conversion since this does not activate the parallel bus. Thus, the microprocessor can continue to use its parallel bus regardless of the state of the AD7872. The interfaces show a timer driving the $\overline{\text{CONVST}}$ input but this could be generated from a decoded address if required.

AD7872 – DSP56000 Serial Interface

Figure 19 shows a serial interface between the AD7872 and the DSP56000. The interface arrangement is two-wire with the AD7872 configured for noncontinuous clock operation CONTROL = 0 V). The DSP56000 is configured for Normal Mode Asynchronous Operation with Gated Clock. It is set up for a 16-bit word with SCK as an input and the FSL control bit set to a 0. In this configuration, the DSP56000 assumes valid data on the first falling edge of SCK. Since the AD7872 provides valid data on this first edge, there is no need for a strobe or framing pulse for the data. SCLK and SDATA are three-stated when the AD7872 is not performing a conversion. During conversion data is valid on the SDATA output of the AD7872 and is clocked into the Receive Data Shift Register of the DSP56000. When this register has received 16 bits of data, it generates an internal interrupt on the DSP56000 to read the data from the register.

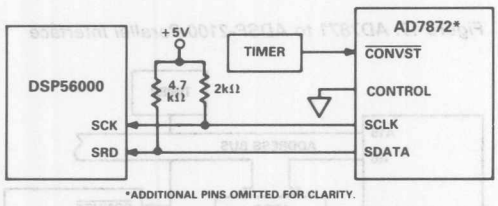

Figure 19. AD7872 to DSP56000 Interface

The DSP56000 and AD7872 can also be configured for continuous clock operation. In this case a strobe pulse is required by the DSP56000 to indicate when data is valid. The $\overline{\text{SSTRB}}$ output of the AD7872 is inverted and applied to the SC1 input of the DSP56000 to provide this strobe pulse. All other conditions and connections are the same as for the gated clock operation.

AD7872 – TMS32020/C25 Serial Interface

Figure 20 shows a serial interface between the AD7872 and the TMS32020/C25. The AD7872 is configured for continuous clock operation. Note, the ADC will not interface correctly to the TMS32020/C25 if it is configured for a noncontinuous clock. Data is clocked into the Data Receive Register (DRR) of the TMS32020/C25 during conversion. As with the previous interfaces, when a 16-bit word is received by the DSP it generates an internal interrupt to read the data from the DRR.

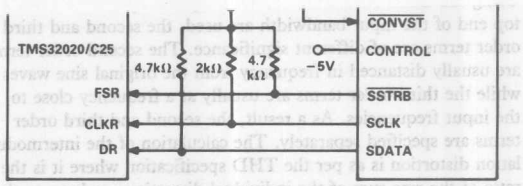

Figure 20. AD7872 to TMS32020/C25 Interface

AD7872 – ADSP-2101/ADSP-2102 Serial Interface

Figure 21 shows a serial interface between the AD7872 and the ADSP-2101/ADSP-2102 DSP Microcomputer. The AD7872 is configured for continuous clock operation. Data is clocked into the serial port register of the microcomputer during conversion. As with the previous interfaces, when a 16-bit data word is received by the ADSP-2101/ADSP-2102 an internal microprocessor interrupt is generated and the data is read from the serial port register.

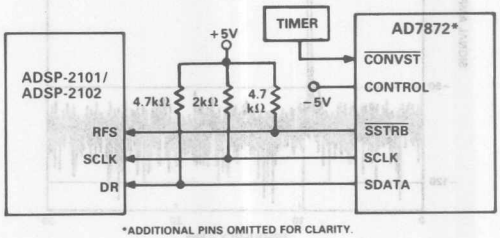

Figure 21. AD7872 to ADSP-2101/ADSP-2101 Serial Interface

STAND-ALONE OPERATION

The AD7871 can be used in its Mode 2, parallel mode for stand-alone operation. In this case, conversion is initiated with a pulse to the $\overline{\text{CS}}$ input. This pulse must be longer than the conversion time of the ADC. The $\overline{\text{BUSY}}$ output is used to drive the $\overline{\text{RD}}$ input. Data is latched from the AD7871 DB0–DB11 outputs to an external latch on the rising edge of $\overline{\text{BUSY}}$.

APPLICATION HINTS

Good printed circuit board (PCB) layout is as important as the circuit design itself in achieving high speed A/D performance. The AD7871/AD7872 is required to make bit decisions on an LSB size of 366 μV. Thus, the designer has to be conscious of noise both in the ADC itself and in the preceding analog circuitry. Switching mode power supplies are not recommended as the switching spikes will feed through to the comparator causing noisy code transitions. Other causes of concern are ground loops and digital feedthrough from microprocessors. These are factors which influence any ADC, and a proper PCB layout which minimizes these effects is essential for best performance.

LAYOUT HINTS

Ensure that the layout for the printed circuit board has the digital and analog signal lines separated as much as possible. Take care not to run a digital track alongside an analog signal track. Guard (screen) the analog input with AGND.

Establish a single point analog ground (star ground) separate from the logic system ground at the AD7871/AD7872 AGND pin or as close as possible to the AD7871/AD7872. Connect all other grounds and the AD7871/AD7872 DGND to this single analog ground point. Do not connect any other digital grounds to this analog ground point.

Low impedance analog and digital power supply common returns are essential to low noise operation of the ADC, so make the foil width for these tracks as wide as possible. The use of ground planes minimizes impedance paths and also guards the analog circuitry from digital noise. The circuit layout of Figures 26 and 27 have both analog and digital ground planes which are kept separated and only joined together at the AD7871/AD7872 AGND pin.

NOISE

Keep the input signal leads to V_{IN} and signal return leads from AGND as short as possible to minimize input noise coupling. In applications where this is not possible, use a shielded cable between the source and the ADC. Reduce the ground circuit impedance as much as possible since any potential difference in grounds between the signal source and the ADC appears as an error voltage in series with the input signal.

DATA ACQUISITION BOARD

Figure 24 shows the AD7871/AD7872 in a data acquisition circuit. The corresponding printed circuit board (PCB) layout has three interface ports: one serial and two parallel. Note that the AD7871/AD7872 serial lines are buffered by a 74HC244. This allows long lines with large capacitive loads to be driven. One of the parallel ports is directly compatible with the ADSP-2100 evaluation board expansion connector.

The only additional component required for a full data acquisition system is an anti-aliasing filter. There is a component grid provided near the analog input on the PCB which may be used for such a filter or any other input conditioning circuitry. To facilitate this option, there is a shorting plug (labelled LK1 on the PCB) on the analog input track. If this shorting plug is used, the analog input connects to the buffer amplifier driving the AD7871/AD7872; if this shorting plug is omitted, a wire link can be used to connect the analog input to the PCB component grid.

INTERFACE CONNECTIONS

There are two parallel connectors labeled SKT4 and SKT6 and one serial connector labeled SKT5. A shorting plug option (LK3 in Figure 24) configures the ADC for the appropriate interface.

SKT6 is a 96-contact (3-row) Eurocard connector which is directly compatible with the ADSP-2100 Evaluation Board Prototype Expansion Connector. The expansion connector on the ADSP-2100 has eight decoded chip enable outputs labeled ECE1 to ECE8. ECE6 is used to drive the AD7871 $\overline{CS}$ input on the board. To avoid selecting the on-board RAM sockets at the same time, LK6 on the ADSP-2100 board must be removed. In addition, the ADSP-2100 expansion connector has four interrupts labelled EIRQ0 to EIRQ3. The AD7871 $\overline{BUSY/INT}$ output connects to EIRQ0. There is a single wait state generator connected to EDMACK to allow the AD7871 to interface to the faster versions of the ADSP-2100.

SKT4 is a 26-way (2-row) IDC connector. This contains the same signal contacts as SKT6 except for EDMACK which is connected to SKT6 only. It also contains decoded R/$\overline{W}$ and $\overline{STRB}$ inputs which are necessary for TMS32020 interfacing.

SKT5 is a 5-way D-type connector which is meant for serial interfacing only. An inverted DB11/SCLK output is also provided on this connector for systems which accept data on a rising clock edge.

SKT1, SKT2 and SKT3 are three BNC connectors which provide connections for the analog input, the $\overline{CONVST}$ input and an external clock.

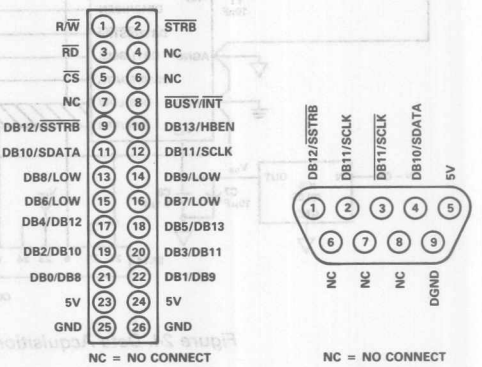

Figure 22. SKT4 Pinout *Figure 23. SKT5 Pinout*

POWER SUPPLY CONNECTIONS

The PCB requires two analog power supplies and one 5 V logic supply. The analog supplies are labelled V+ and V−, and the range for both supplies is 12 V to 15 V. Connection to the 5 V digital supply is made through any of the connectors SKT4 to SKT6. The ±5 V supply required by the AD7871 and AD7872 is generated from voltage regulators on the V+ and V− power supplies input (IC6 and IC7 in Figure 24).

SHORTING PLUG OPTIONS

There are seven shorting plug options which must be set before using the board. These are outlined below:

LK1 Connects the analog input to a buffer amplifier. The analog input may also be connected to a component grid for signal conditioning.
LK2 Selects either the AD7871/AD7872 internal clock or an external clock source.
LK3 Configures the AD7871 14/$\overline{8}$/CLK input for the appropriate serial or parallel interface.
LK4 Connects the AD7871 $\overline{RD}$ input directly to the two parallel connectors or to a decoded $\overline{STRB}$ and R/$\overline{W}$ input.
LK5 Connects the pull-up resistor R3 to $\overline{SSTRB}$.
LK6 Connects the pull-up resistor R4 to SCLK.
LK7 Connects the pull-up resistor R5 to SDATA.

Note that LK5 to LK7 should be removed for parallel interfacing.

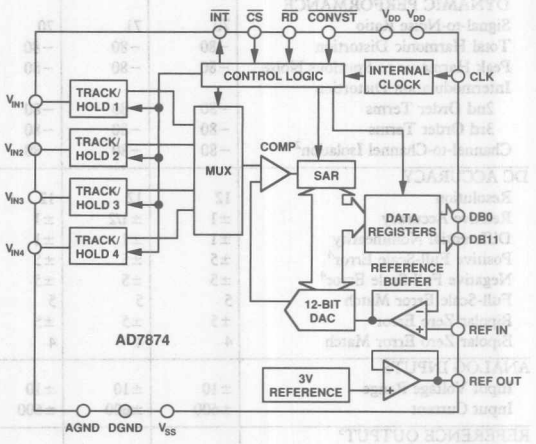
LC²MOS 4-Channel, 12-Bit Simultaneous Sampling Data Acquisition System



AD7874

2

FEATURES
- Four On-Chip Track/Hold Amplifiers
- Simultaneous Sampling of 4 Channels
- Fast 12-Bit ADC with 8 μs Conversion Time/Channel
- 29 kHz Sample Rate for All Four Channels
- On-Chip Reference
- ±10 V Input Range
- ±5 V Supplies

APPLICATIONS
- Sonar
- Motor Controllers
- Adaptive Filters
- Digital Signal Processing

FUNCTIONAL BLOCK DIAGRAM

GENERAL DESCRIPTION

The AD7874 is a four-channel simultaneous sampling, 12-bit data acquisition system. The part contains a high speed 12-bit ADC, on-chip reference, on-chip clock and four track/hold amplifiers. This latter feature allows the four input channels to be sampled simultaneously, thus preserving the relative phase information of the four input channels, which is not possible if all four channels share a single track/hold amplifier. This makes the AD7874 ideal for applications such as phased-array sonar and ac motor controllers where the relative phase information is important.

The aperture delay of the four track/hold amplifiers is small and specified with minimum and maximum limits. This allows several AD7874s to sample multiple input channels simultaneously without incurring phase errors between signals connected to several devices. A reference output/reference input facility also allows several AD7874s to be driven from the same reference source.

In addition to the traditional dc accuracy specifications such as linearity, full-scale and offset errors, the AD7874 is also fully specified for dynamic performance parameters including distortion and signal-to-noise ratio.

The AD7874 is fabricated in Analog Devices' Linear Compatible CMOS (LC²MOS) process, a mixed technology process that combines precision bipolar circuits with low-power CMOS logic. The part is available in a 28-pin, 0.6" wide, plastic or hermetic dual-in-line package (DIP), in a 28-terminal leadless ceramic chip carrier (LCCC) and in a 28-pin SOIC.

PRODUCT HIGHLIGHTS

1. Simultaneous Sampling of Four Input Channels.
   Four input channels, each with its own track/hold amplifier, allow simultaneous sampling of input signals. Track/hold acquisition time is 2 μs, and the conversion time per channel is 8 μs, allowing 29 kHz sample rate for all four channels.
2. Tight Aperture Delay Matching.
   The aperture delay for each channel is small and the aperture delay matching between the four channels is less than 4 ns. Additionally, the aperture delay specification has upper and lower limits allowing multiple AD7874s to sample more than four channels.
3. Fast Microprocessor Interface.
   The high speed digital interface of the AD7874 allows direct connection to all modern 16-bit microprocessors and digital signal processors.

AD7874—SPECIFICATIONS

NOTES

[1]Temperature ranges are as follows: A, B Versions: −40°C to +85°C; S Version: −55°C to +125°C.

[2]See Terminology.

[3]Sample tested @ +25°C to ensure compliance.

[4]Measured with respect to the REF IN voltage and includes bipolar offset error.

[5]For capacitive loads greater than 50 pF a series resistor is required.

Specifications subject to change without notice.

TIMING CHARACTERISTICS[1] (V_{DD} = +5 V ± 5%, V_{SS} = −5 V ± 5%, AGND = DGND = 0 V, f_{CLK} = 2.5 MHz external unless otherwise stated.)

Parameter	A, B Versions	S Version	Units	Conditions/Comments
t_1	50	50	ns min	$\overline{CONVST}$ Pulse Width
t_2	0	0	ns min	$\overline{CS}$ to $\overline{RD}$ Setup Time
t_3	**60**	**70**	ns min	$\overline{RD}$ Pulse Width
t_4	0	0	ns min	$\overline{CS}$ to $\overline{RD}$ Hold Time
t_5	60	60	ns max	$\overline{RD}$ to $\overline{INT}$ Delay
t_6[2]	**57**	**70**	ns max	Data Access Time after $\overline{RD}$
t_7[3]	5	5	ns min	Bus Relinquish Time after $\overline{RD}$
	45	**50**	ns max	
t_8	130	150	ns min	Delay Time between Reads
t_{CONV}	31	31	µs min	$\overline{CONVST}$ to $\overline{INT}$, External Clock
	32.5	32.5	µs max	$\overline{CONVST}$ to $\overline{INT}$, External Clock
	31	31	µs min	$\overline{CONVST}$ to $\overline{INT}$, Internal Clock
	35	35	µs max	$\overline{CONVST}$ to $\overline{INT}$, Internal Clock
t_{CLK}	10	10	µs max	Minimum Input Clock Period

NOTES

[1]Timing Specifications in **bold print** are 100% production tested. All other times are sample tested at +25°C to ensure compliance. All input signals are specified with tr = tf = 5 ns (10% to 90% of +5 V) and timed from a voltage level of 1.6 V.

[2]t_6 is measured with the load circuit of Figure 1 and defined as the time required for an output to cross 0.8 V or 2.4 V.

[3]t_7 is derived from the measured time taken by the data outputs to change 0.5 V when loaded with the circuit of Figure 2. The measured number is then extrapolated back to remove the effects of charging or discharging the 50 pF capacitor. This means that the time, t_7, quoted in the timing characteristics is the true bus relinquish time of the part and as such is independent of external bus loading capacitances.

Specifications subject to change without notice.

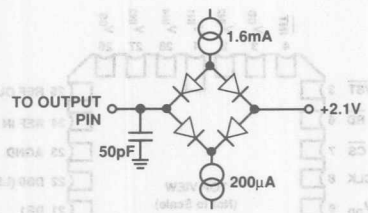

Figure 1. Load Circuit for Access Time

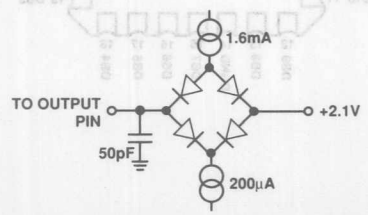

Figure 2. Load Circuit for Bus Relinquish Time

ABSOLUTE MAXIMUM RATINGS*

(T_A = +25°C unless otherwise noted)

V_{DD} to AGND	−0.3 V to +7 V
V_{DD} to DGND	−0.3 V to +7 V
V_{SS} to AGND	+0.3 V to −7 V
AGND to DGND	−0.3 V to V_{DD}+0.3 V
V_{IN} to AGND	−15 V to +15 V
REF OUT to AGND	0 V to V_{DD}
Digital Inputs to DGND	−0.3 V to V_{DD} +0.3 V
Digital Outputs to DGND	−0.3 V to V_{DD} +0.3 V
Operating Temperature Range	
Commercial (A, B Versions)	−40°C to +85°C
Extended (S Version)	−55°C to +125°C
Storage Temperature Range	−65°C to +150°C
Lead Temperature (Soldering, 10 secs)	+300°C
Power Dissipation (Any Package) to +75°C	1,000 mW
Derates above +75°C by	10 mW/°C

*Stresses above those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. This is a stress rating only and functional operation of the device at these or any other conditions above those listed in the operational sections of this specifications is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

CAUTION

ESD (electrostatic discharge) sensitive device. The digital control inputs are diode protected; however, permanent damage may occur on unconnected devices subject to high energy electrostatic fields. Unused devices must be stored in conductive foam or shunts. The protective foam should be discharged to the destination socket before devices are inserted.

PIN CONFIGURATIONS

DIP and SOIC

LCCC

PIN FUNCTION DESCRIPTION

Pin	Mnemonic	Description
1	V_{IN1}	Analog Input Channel 1. This is the first of the four input channels to be converted in a conversion cycle. Analog input voltage range is ±10 V.
2	V_{IN2}	Analog Input Channel 2. Analog input voltage range is ±10 V.
3	V_{DD}	Positive supply voltage, +5 V ± 5%. This pin should be decoupled to AGND.
4	$\overline{INT}$	Interrupt. Active low logic output indicating converter status. See Figure 7.
5	$\overline{CONVST}$	Convert Start. Logic Input. A low to high transition on this input puts the track/hold into its hold mode and starts conversion. The four channels are converted sequentially, Channel 1 to Channel 4. The $\overline{CONVST}$ input is asynchronous to CLK and independent of $\overline{CS}$ and $\overline{RD}$.
6	$\overline{RD}$	Read. Active low logic input. This input is used in conjunction with $\overline{CS}$ low to enable the data outputs. Four successive reads after a conversion will read the data from the four channels in the sequence, Channel 1, 2, 3, 4.
7	$\overline{CS}$	Chip Select. Active low logic input. The device is selected when this input is active.
8	CLK	Clock Input. An external TTL-compatible clock may be applied to this input pin. Alternatively, tying this pin to V_{SS} enables the internal laser trimmed clock oscillator.
9	V_{DD}	Positive Supply Voltage, +5 V ± 5%. Same as Pin 3; both pins must be tied together at the package. This pin should be decoupled to DGND.
10	DB11	Data Bit 11 (MSB). Three-state TTL output. Output coding is 2s complement.
11–13	DB10–DB8	Data Bit 10 to Data Bit 8. Three-state TTL outputs.
14	DGND	Digital Ground. Ground reference for digital circuitry.
15–21	DB7–DB1	Data Bit 7 to Data Bit 1. Three-state TTL outputs.
22	DB0	Data Bit 0 (LSB). Three-state TTL output.
23	AGND	Analog Ground. Ground reference for track/hold, reference and DAC.
24	REF IN	Voltage Reference Input. The reference voltage for the part is applied to this pin. It is internally buffered, requiring an input current of only ±1 μA. The nominal reference voltage for correct operation of the AD7874 is 3 V.
25	REF OUT	Voltage Reference Output. The internal 3 V analog reference is provided at this pin. To operate the AD7874 with internal reference, REF OUT is connected to REF IN. The external load capability of the reference is 500 μA.
26	V_{SS}	Negative Supply Voltage, −5 V ± 5%.
27	V_{IN3}	Analog Input Channel 3. Analog input voltage range is ±10 V.
28	V_{IN4}	Analog Input Channel 4. Analog input voltage range is ±10 V.

TERMINOLOGY

ACQUISITION TIME
Acquisition Time is the time required for the output of the track/hold amplifiers to reach their final values, within ±1/2 LSB, after the falling edge of $\overline{INT}$ (the point at which the track/holds return to track mode). This includes switch delay time, slewing time and settling time for a full-scale voltage change.

APERTURE DELAY
Aperture Delay is defined as the time required by the internal switches to disconnect the hold capacitors from the inputs. This produces an effective delay in sample timing. It is measured by applying a step input and adjusting the $\overline{CONVST}$ input position until the output code follows the step input change.

APERTURE DELAY MATCHING
Aperture Delay Matching is the maximum deviation in aperture delays across the four on-chip track/hold amplifiers.

APERTURE JITTER
Aperture Jitter is the uncertainty in aperture delay caused by internal noise and variation of switching thresholds with signal level.

DROOP RATE
Droop Rate is the change in the held analog voltage resulting from leakage currents.

CHANNEL-TO-CHANNEL ISOLATION
Channel-to-Channel Isolation is a measure of the level of crosstalk between channels. It is measured by applying a full-scale 1 kHz signal to the other three inputs. The figure given is the worst case across all four channels.

SNR, THD, IMD
See DYNAMIC SPECIFICATIONS section.

CONVERTER DETAILS

The AD7874 is a complete 12-bit, 4-channel data acquisition system. It is comprised of a 12-bit successive approximation ADC, four high speed track/hold circuits, a four-channel analog multiplexer and a 3 V Zener reference. The ADC uses a successive-approximation technique and is based on a fast-settling, voltage-switching DAC, a high speed comparator, a fast CMOS SAR and high speed logic.

Conversion is initiated on the rising edge of $\overline{\text{CONVST}}$. All four input track/holds go from track to hold on this edge. Conversion is first performed on the Channel 1 input voltage, then Channel 2 is converted and so on. The four results are stored in on-chip registers. When all four conversions have been completed, $\overline{\text{INT}}$ goes low indicating that data can be read from these locations. The conversion sequence takes either 78 or 79 rising clock edges depending on the synchronization of $\overline{\text{CONVST}}$ with CLK. Internal delays and reset times bring the total conversion time from $\overline{\text{CONVST}}$ going high to $\overline{\text{INT}}$ going low to 32.5 μs maximum for a 2.5 MHz external clock. The AD7874 uses an implicit addressing scheme whereby four successive reads to the same memory location access the four data words sequentially. The first read accesses Channel 1 data, the second read accesses Channel 2 data and so on. Individual data registers cannot be accessed independently.

INTERNAL REFERENCE

The AD7874 has an on-chip temperature compensated buried Zener reference which is factory trimmed to 3 V ±10 mV (see Figure 3). The reference voltage is provided at the REF OUT pin. This reference can be used to provide both the reference voltage for the ADC and the bipolar bias circuitry. This is achieved by connecting REF OUT to REF IN.

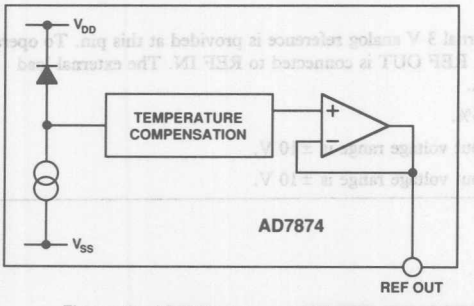

Figure 3. AD7874 Internal Reference

The reference can also be used as a reference for other components and is capable of providing up to 500 μA to an external load. In systems using several AD7874s, using the REF OUT of one device to provide the REF IN for the other devices ensures good full-scale tracking between all the AD7874s. Because the AD7874 REF IN is buffered, each AD7874 presents a high impedance to the reference so one AD7874 REF OUT can drive several AD7874 REF INs.

The maximum recommended capacitance on REF OUT for normal operation is 50 pF. If the reference is required for other system uses, it should be decoupled to AGND with a 200 Ω resistor in series with a parallel combination of a 10 μF tantalum capacitor and a 0.1 μF ceramic capacitor.

EXTERNAL REFERENCE

In some applications, the user may require a system reference or some other external reference to drive the AD7874 reference input. Figure 4 shows how the AD586 5 V reference can be used to provide the 3 V reference required by the AD7874 REF IN.

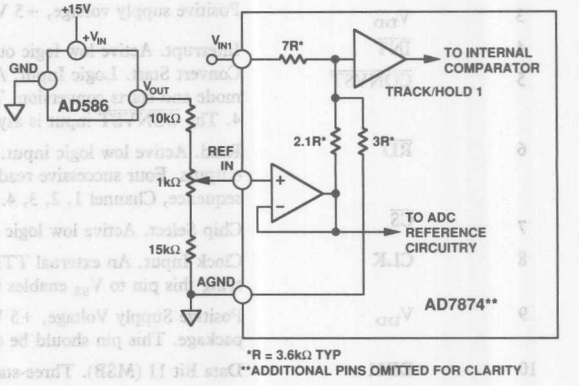

Figure 4. AD586 Driving AD7874 REF IN

TRACK-AND-HOLD AMPLIFIER

The track-and-hold amplifier on each analog input of the AD7874 allows the ADC to accurately convert an input sine wave of 20 V p–p amplitude to 12-bit accuracy. The input bandwidth of the track/hold amplifier is greater than the Nyquist rate of the ADC even when the ADC is operated at its maximum throughput rate. The small signal 3 dB cutoff frequency occurs typically at 500 kHz.

The four track/hold amplifiers sample their respective input channels simultaneously. The aperture delay of the track/hold circuits is small and, more importantly, is well matched across the four track/holds on one device and also well matched from device to device. This allows the relative phase information between different input channels to be accurately preserved. It also allows multiple AD7874s to sample more than four channels simultaneously.

The operation of the track/hold amplifiers is essentially transparent to the user. Once conversion is initiated, the four channels are automatically converted and there is no need to select which channel is to be digitized.

ANALOG INPUT

The analog input of Channel 1 of the AD7874 is as shown in Figure 4. The analog input range is ±10 V into an input resistance of typically 30 kΩ. The designed code transitions occur midway between successive integer LSB values (i.e., 1/2 LSB, 3/2 LSBs, 5/2 LSBs, . . . FS − 3/2 LSBs). The output code is 2s complement binary with 1 LSB = FS/4096 = 20 V/4096 = 4.88 mV. The ideal input/output transfer function is shown in Figure 5.

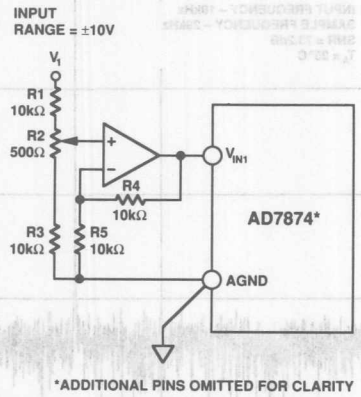

Figure 5. Input/Output Transfer Function

OFFSET AND FULL-SCALE ADJUSTMENT

In most Digital Signal Processing (DSP) applications, offset and full-scale errors have little or no effect on system performance. Offset error can always be eliminated in the analog domain by ac coupling. Full-scale error effect is linear and does not cause problems as long as the input signal is within the full dynamic range of the ADC. Invariably, some applications will require that the input signal span the full analog input dynamic range. In such applications, offset and full-scale error will have to be adjusted to zero.

Figure 6 shows a circuit which can be used to adjust the offset and full-scale errors on the AD7874 (Channel 1 is shown for example purposes only). Where adjustment is required, offset error must be adjusted before full-scale error. This is achieved by trimming the offset of the op amp driving the analog input of the AD7874 while the input voltage is a 1/2 LSB below analog ground. The trim procedure is as follows: apply a voltage of −2.44 mV (−1/2 LSB) at V_1 in Figure 6 and adjust the op amp offset voltage until the ADC output code flickers between 1111 1111 1111 and 0000 0000 0000.

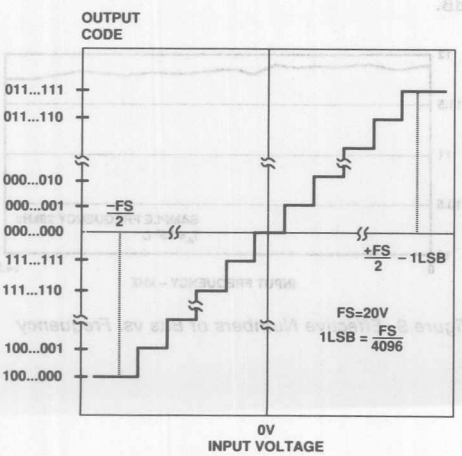

Figure 6. AD7874 Full-Scale Adjust Circuit

Gain error can be adjusted at either the first code transition (ADC negative full scale) or the last code transition (ADC positive full scale). The trim procedures for both cases are as follows:

Positive Full-Scale Adjust
Apply a voltage of +9.9927 V (FS/2 − 3/2 LSBs) at V_1. Adjust R2 until the ADC output code flickers between 0111 1111 1110 and 0111 1111 1111.

Negative Full-Scale Adjust
Apply a voltage of −9.9976 V (−FS + 1/2 LSB) at V_1 and adjust R2 until the ADC output code flickers between 1000 0000 0000 and 1000 0000 0001.

An alternative scheme for adjusting full-scale error in systems which use an external reference is to adjust the voltage at the REF IN pin until the full-scale error for any of the channels is adjusted out. The good full-scale matching of the channels will ensure small full-scale errors on the other channels.

TIMING AND CONTROL

Conversion is initiated on the AD7874 by asserting the $\overline{\text{CONVST}}$ input. This $\overline{\text{CONVST}}$ input is an asynchronous input which is independent of the ADC clock. This is essential for applications where precise sampling in time is important. In these applications, the signal sampling must occur at exactly equal intervals to minimize errors due to sampling uncertainty or jitter. In these cases, the $\overline{\text{CONVST}}$ input is driven from a timer or precise clock source. Once conversion is started, $\overline{\text{CONVST}}$ should not be asserted again until conversion is complete on all four channels.

In applications where precise time interval sampling is not critical, the $\overline{\text{CONVST}}$ pulse can be generated from a microprocessor WRITE or READ line gated with a decoded address (different to the AD7874 $\overline{\text{CS}}$ address). $\overline{\text{CONVST}}$ should not be derived from a decoded address alone because very short $\overline{\text{CONVST}}$ pulses (which may occur in some microprocessor systems as the address bus is changing at the start of an instruction cycle) could initiate a conversion.

All four track/hold amplifiers go from track to hold on the rising edge of the $\overline{\text{CONVST}}$ pulse. The four track/hold amplifiers remain in their hold mode while all four channels are converted. The rising edge of $\overline{\text{CONVST}}$ also initiates a conversion on the Channel 1 input voltage (V_{IN1}). When conversion is complete on Channel 1, its result is stored in Data Register 1, one of four on-chip registers used to store the conversion results. When the result from the first conversion is stored, conversion is initiated on the voltage held by track/hold 2. When conversion has been completed on the voltage held by track/hold 4 and its result is stored in Data Register 4, $\overline{\text{INT}}$ goes low to indicate that the conversion process is complete.

The sequence in which the channel conversions takes place is automatically taken care of by the AD7874. This means that the user does not have to provide address lines to the AD7874 or worry about selecting which channel is to be digitized.

Reading data from the device consists of four read operations to the same microprocessor address. Addressing of the four on-chip data registers is again automatically taken care of by the AD7874. The first read operation to the AD7874 after conversion always accesses data from Data Register 1 (i.e., the conversion result from the V_{IN1} input). $\overline{\text{INT}}$ is reset high on the falling edge of $\overline{\text{RD}}$ during this first read operation. The second read always

CONVST. A read operation to the AD7874 should not be attempted during conversion. The timing diagram for the AD7874 conversion sequence is shown in Figure 7.

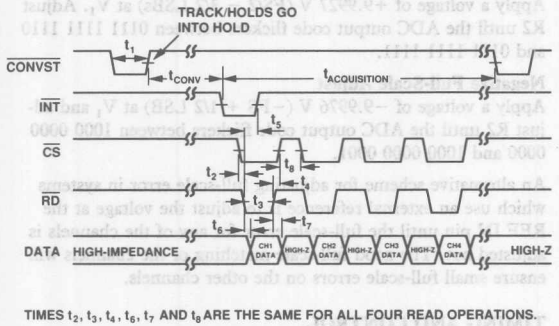

Figure 7. AD7874 Timing Diagram

AD7874 DYNAMIC SPECIFICATIONS

The AD7874 is specified and 100% tested for dynamic performance specifications as well as traditional dc specifications such as Integral and Differential Nonlinearity. These ac specifications are required for the signal processing applications such as phased array sonar, adaptive filters and spectrum analysis. These applications require information on the ADC's effect on the spectral content of the input signal. Hence, the parameters for which the AD7874 is specified include SNR, harmonic distortion, intermodulation distortion and peak harmonics. These terms are discussed in more detail in the following sections.

Signal-to-Noise Ratio (SNR)

SNR is the measured signal to noise ratio at the output of the ADC. The signal is the rms magnitude of the fundamental. Noise is the rms sum of all the nonfundamental signals up to half the sampling frequency (fs/2) excluding dc. SNR is dependent upon the number of quantization levels used in the digitization process; the more levels, the smaller the quantization noise. The theoretical signal to noise ratio for a sine wave input is given by

$$SNR = (6.02N + 1.76)\ dB \quad \ldots\ldots\ldots\ldots\ldots\ldots (1)$$

where N is the number of bits.

Thus for an ideal 12-bit converter, SNR = 74 dB.

The output spectrum from the ADC is evaluated by applying a sine wave signal of very low distortion to the V_{IN} input which is sampled at a 29 kHz sampling rate. A Fast Fourier Transform (FFT) plot is generated from which the SNR data can be obtained. Figure 8 shows a typical 2048 point FFT plot of the AD7874BN with an input signal of 10 kHz and a sampling frequency of 29 kHz. The SNR obtained from this graph is 73.2 dB. It should be noted that the harmonics are taken into account when calculating the SNR.

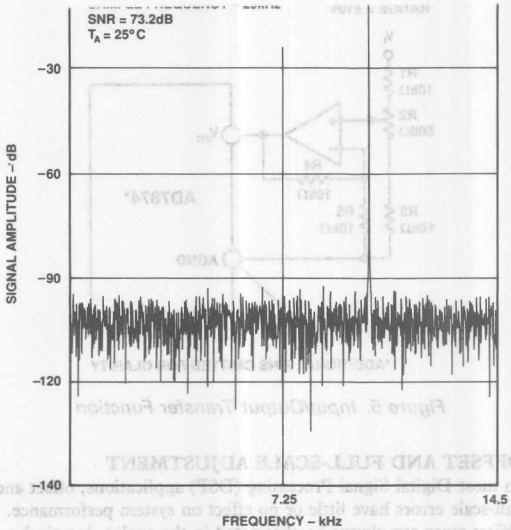

Figure 8. AD7874 FFT Plot

Effective Number of Bits

The formula given in Equation 1 relates the SNR to the number of bits. Rewriting the formula, as in Equation 2, it is possible to get a measure of performance expressed in effective number of bits (N).

$$N = \frac{SNR - 1.76}{6.02} \quad \ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots (2)$$

The effective number of bits for a device can be calculated directly from its measured SNR.

Figure 9 shows a typical plot of effective number of bits versus frequency for an AD7874BN with a sampling frequency of 29 kHz. The effective number of bits typically falls between 11.75 and 11.87 corresponding to SNR figures of 72.5 dB and 73.2 dB.

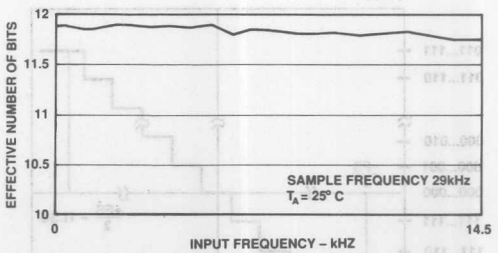

Figure 9. Effective Numbers of Bits vs. Frequency

Total Harmonic Distortion (THD)

Total Harmonic Distortion (THD) is the ratio of the rms sum of harmonics to the rms value of the fundamental. For the AD7874, THD is defined as

$$THD = 20\ log\ \frac{\sqrt{V_2^2 + V_3^2 + V_4^2 + V_5^2 + V_6^2}}{V_1}$$

where V_1 is the rms amplitude of the fundamental and V_2, V_3, V_4, V_5 and V_6 are the rms amplitudes of the second through the sixth harmonic. The THD is also derived from the FFT plot of the ADC output spectrum.

Intermodulation Distortion

With inputs consisting of sine waves at two frequencies, fa and fb, any active device with nonlinearities will create distortion products at sum and difference frequencies of mfa ± nfb where m, n = 0, 1, 2, 3 . . ., etc. Intermodulation terms are those for which neither m or n are equal to zero. For example, the second order terms include (fa + fb) and (fa − fb) while the third order terms include (2fa + fb), (2fa − fb), (fa + 2fb) and (fa − 2fb).

Using the CCIF standard where two input frequencies near the top end of the input bandwidth are used, the second and third order terms are of different significance. The second order terms are usually distanced in frequency from the original sine waves while the third order terms are usually at a frequency close to the input frequencies. As a result, the second and third order terms are specified separately. The calculation of the intermodulation distortion is as per the THD specification where it is the ratio of the rms sum of the individual distortion products to the rms amplitude of the fundamental expressed in dBs. In this case, the input consists of two, equal amplitude, low distortion sine waves. Figure 10 shows a typical IMD plot for the AD7874.

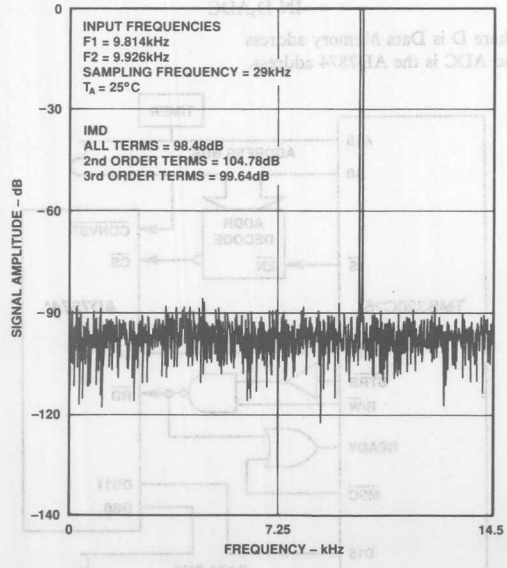

Figure 10. AD7874 IMD Plot

Peak Harmonic or Spurious Noise

Peak Harmonic or Spurious Noise is defined as the ratio of the rms value of the next largest component in the ADC output spectrum (up to fs/2 and excluding dc) to the rms value of the fundamental. Normally, the value of this specification will be determined by the largest harmonic in the spectrum, but for parts where the harmonics are buried in the noise floor the peak will be a noise peak.

AC Linearity Plot

When a sine wave of specified frequency is applied to the V_{IN} input of the AD7874 and several million samples are taken, a histogram showing the frequency of occurrence of each of the 4096 ADC codes can be generated. From this histogram data it is possible to generate an ac integral linearity plot as shown in Figure 11. This shows very good integral linearity performance from the AD7874 at an input frequency of 10 kHz. The absence of large spikes in the plot shows good differential linearity. Simplified versions of the formulae used are outlined below.

$$INL(i) = \left[\frac{(V(i) - V(o)) \cdot 4096}{V(fs) - V(o)}\right] - i$$

where INL(i) is the integral linearity at code i. V(fs) and V(o) are the estimated full-scale and offset transitions, and V(i) is the estimated transition for the ith code.

V(i), the estimated code transition point is derived as follows:

$$V(i) = -A \cdot Cos\ \frac{[\pi \cdot cum\ (i)]}{N}$$

where A is the peak signal amplitude, N is the number of histogram samples

$$\text{and cum (i)} = \sum_{n=0}^{i} \text{V(n) occurrences}$$

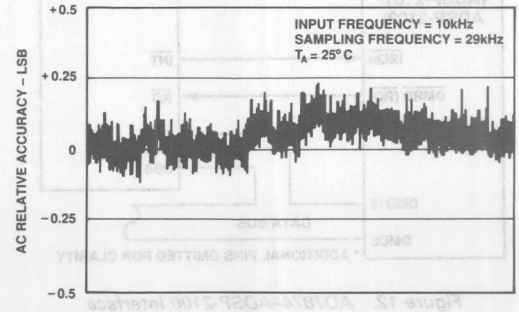

Figure 11. AD7874 AC INL Plot

MICROPROCESSOR INTERFACING

The AD7874 high speed bus timing allows direct interfacing to DSP processors as well as modern 16-bit microprocessors. Suitable microprocessor interfaces are shown in Figures 12 through 16.

AD7874–ADSP-2100 Interface

Figure 12 shows an interface between the AD7874 and the ADSP-2100. Conversion is initiated using a timer which allows very accurate control of the sampling instant on all four channels. The AD7874 $\overline{INT}$ line provides an interrupt to the ADSP-2100 when conversion is completed on all four channels. The four conversion results can then be read from the AD7874 using four successive reads to the same memory address. The following instruction reads one of the four results (this instruction is repeated four times to read all four results in sequence):

MR0 = DM(ADC)

where MR0 is the ADSP-2100 MR0 register and ADC is the AD7874 address.

AD7874–ADSP-2101/ADSP-2102 Interface

The interface outlined in Figure 12 also forms the basis for an interface between the AD7874 and the ADSP-2101/ADSP-2102. The READ line of the ADSP-2101/ADSP-2102 is labeled $\overline{RD}$. In this interface, the $\overline{RD}$ pulse width of the processor can be programmed using the Data Memory Wait State Control Register. The instruction used to read one of the four results is as outlined for the ADSP-2100.

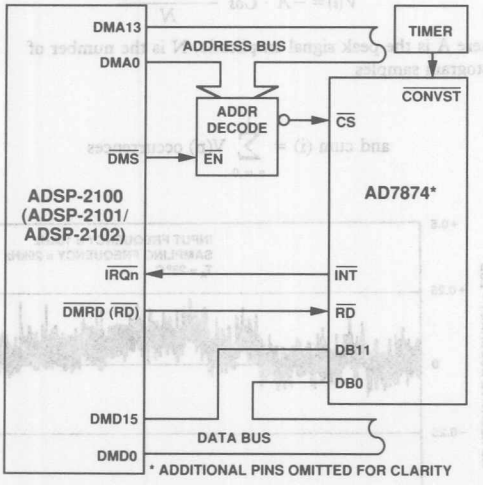

Figure 12. AD7874–ADSP-2100 Interface

AD7874–TMS32010 Interface

An interface between the AD7874 and the TMS32010 is shown in Figure 13. Once again the conversion is initiated using an external timer and the TMS32010 is interrupted when all four conversions have been completed. The following instruction is used to read the conversion results from the AD7874:

IN D,ADC

where D is Data Memory address and ADC is the AD7874 address.

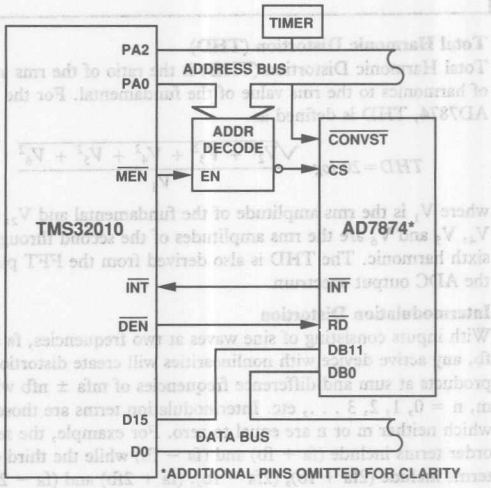

Figure 13. AD7874–TMS32010 Interface

AD7874–TMS320C25 Interface

Figure 14 shows an interface between the AD7874 and the TMS320C25. As with the two previous interfaces, conversion is initiated with a timer and the processor is interrupted when the conversion sequence is completed. The TMS320C25 does not have a separate $\overline{RD}$ output to drive the AD7874 $\overline{RD}$ input directly. This has to be generated from the processor $\overline{STRB}$ and R/$\overline{W}$ outputs with the addition of some logic gates. The $\overline{RD}$ signal is OR-gated with the $\overline{MSC}$ signal to provide the one WAIT state required in the read cycle for correct interface timing. Conversion results are read from the AD7874 using the following instruction:

IN D,ADC

where D is Data Memory address and ADC is the AD7874 address.

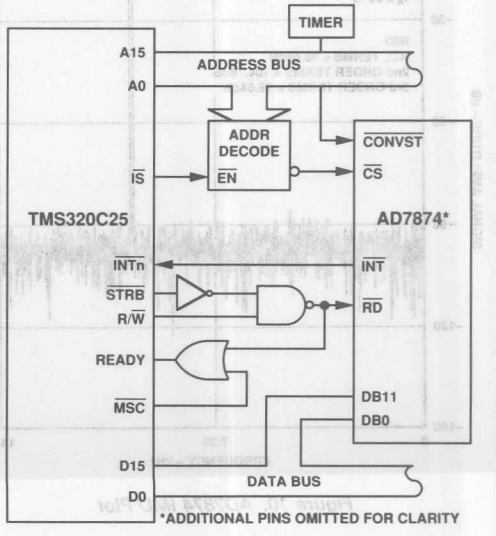

Figure 14. AD7874–TMS320C25 Interface

Some applications may require that the conversion is initiated by the microprocessor rather than an external timer. One option is to decode the AD7874 $\overline{CONVST}$ from the address bus so that a write operation starts a conversion. Data is read at the end of the conversion sequence as before. Figure 16 shows an example of initiating conversion using this method. Note that for all interfaces, a read operation should not be attempted during conversion.

AD7874–MC68000 Interface

An interface between the AD7874 and the MC68000 is shown in Figure 15. As before, conversion is initiated using an external timer. The AD7874 $\overline{INT}$ line can be used to interrupt the processor or, alternatively, software delays can ensure that conversion has been completed before a read to the AD7874 is attempted. Because of the nature of its interrupts, the 68000 requires additional logic (not shown in Figure 15) to allow it to be interrupted correctly. For further information on 68000 interrupts, consult the 68000 users manual.

The MC68000 $\overline{AS}$ and R/$\overline{W}$ outputs are used to generate a separate $\overline{RD}$ input signal for the AD7874. $\overline{CS}$ is used to drive the 68000 $\overline{DTACK}$ input to allow the processor to execute a normal read operation to the AD7874. The conversion results are read using the following 68000 instruction:

MOVE.W ADC,D0

where D0 is the 68000 D0 register
and ADC is the AD7874 address.

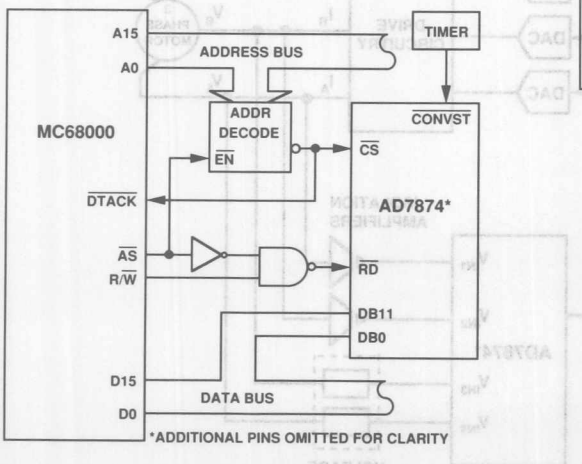

Figure 15. AD7874–MC68000 Interface

AD7874–8086 Interface

Figure 16 shows an interface between the AD7874 and the 8086 microprocessor. Unlike the previous interface examples, the microprocessor initiates conversion. This is achieved by gating the 8086 $\overline{WR}$ signal with a decoded address output (different to the AD7874 $\overline{CS}$ address). The AD7874 $\overline{INT}$ line is used to interrupt the microprocessor when the conversion sequence is completed. Data is read from the AD7874 using the following instruction:

MOV AX,ADC

where AX is the 8086 accumulator
and ADC is the AD7874 address.

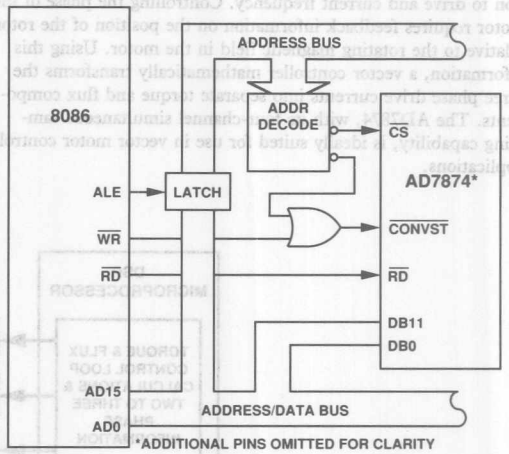

Figure 16. AD7874–8086 Interface

APPLICATIONS

Vector Motor Control

The current drawn by a motor can be split into two components: one produces torque and the other produces magnetic flux. For optimal performance of the motor, these two components should be controlled independently. In conventional methods of controlling a three-phase motor, the current (or voltage) supplied to the motor and the frequency of the drive are the basic control variables. However, both the torque and flux are functions of current (or voltage) and frequency. This coupling effect can reduce the performance of the motor because, for example, if the torque is increased by increasing the frequency, the flux tends to decrease.

Vector control of an ac motor involves controlling phase in addition to drive and current frequency. Controlling the phase of the motor requires feedback information on the position of the rotor relative to the rotating magnetic field in the motor. Using this information, a vector controller mathematically transforms the three phase drive currents into separate torque and flux components. The AD7874, with its four-channel simultaneous sampling capability, is ideally suited for use in vector motor control applications.

A block diagram of a vector motor control application using the AD7874 is shown in Figure 17. The position of the field is derived by determining the current in each phase of the motor. Only two phase currents need to be measured because the third can be calculated if two phases are known. Channel 1 and Channel 2 of the AD7874 are used to digitize this information. Simultaneous sampling is critical to maintain the relative phase information between the two channels. A current sensing isolation amplifier, transformer or Hall effect sensor is used between the motor and the AD7874. Rotor information is obtained by measuring the voltage from two of the inputs to the motor. Channel 3 and Channel 4 of the AD7874 are used to obtain this information. Once again the relative phase of the two channels is important. A DSP microprocessor is used to perform the mathematical transformations and control loop calculations on the information fed back by the AD7874.

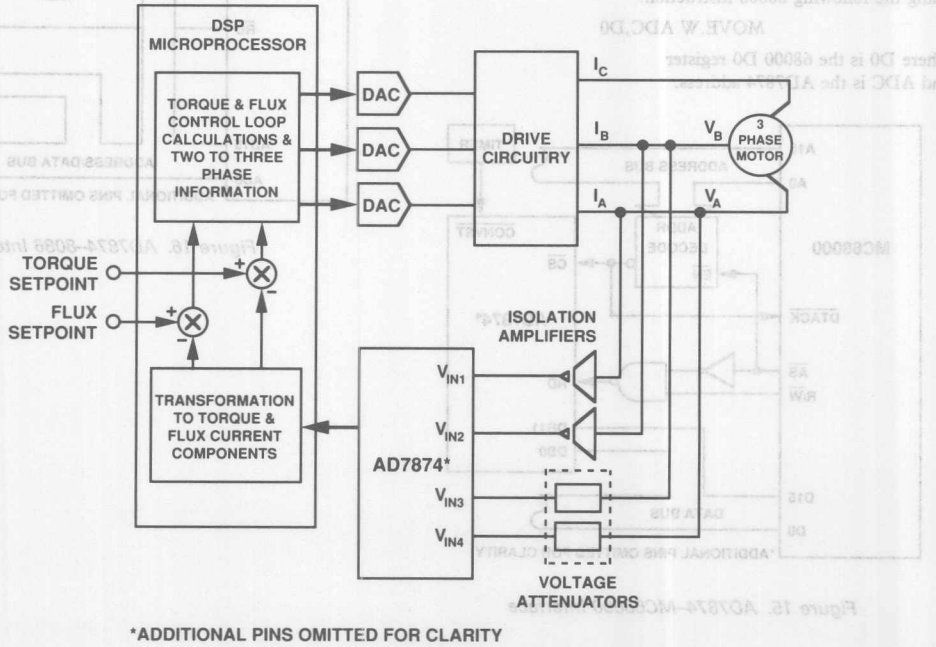

Figure 17. Vector Motor Control Using the AD7874

MULTIPLE AD7874s

Figure 18 shows a system where a number of AD7874s can be configured to handle multiple input channels. This type of configuration is common in applications such as sonar, radar, etc. The AD7874 is specified with maximum and minimum limits on aperture delay. This means that the user knows the maximum difference in the sampling instant between all channels. This allows the user to maintain relative phase information between the different channels.

A common read signal from the microprocessor drives the $\overline{RD}$ input of all AD7874s. Each AD7874 is designated a unique address selected by the address decoder. The reference output of AD7874 number 1 is used to drive the reference input of all other AD7874s in the circuit shown in Figure 18. One REF OUT pin can drive several AD7874 REF IN pins. Alternatively, an external or system reference can be used to drive all REF IN inputs. A common reference ensures good full-scale tracking between all channels.

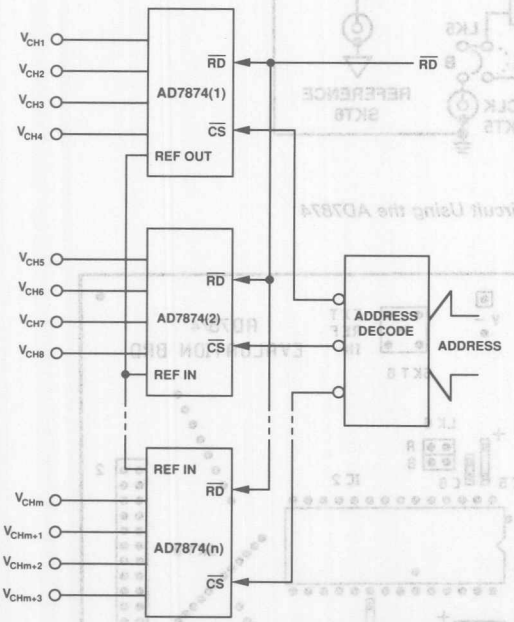

Figure 18. Multiple AD7874s in Multichannel System

DATA ACQUISITION BOARD

Figure 20 shows the AD7874 in a data acquisition circuit. The corresponding printed circuit board (PCB) layout and silkscreen are shown in Figures 21 to 23. A 26-contact IDC connector provides for a microprocessor connection to the board.

A component grid is provided near the analog inputs on the PCB which may be used to provide antialiasing filters for the analog input channels or to provide signal conditioning circuitry. To facilitate this option, four shorting plugs (labeled LK1 to LK4 on the PCB) are provided on the analog inputs, one plug per input. If the shorting plug for a particular channel is used, the input signal connects to the buffer amplifier driving the analog input of the ADC. If the shorting plug is omitted, a wire link can be used to connect the input signal to the PCB component grid.

Microprocessor connections to the board are made via a 26-contact IDC connector, SKT8, the pinout for which is shown in Figure 19. This connector contains all data, control and status signals of the AD7874 (with the exception of the CLK input and the $\overline{CONVST}$ input which are provided via SKT5 and SKT7, respectively). It also contains decoded R/$\overline{W}$ and $\overline{STRB}$ inputs which are necessary for TMS32020 interfacing (and also for 68000 interfacing although pin labels on the 68000 are different). Note that the AD7874 $\overline{CS}$ input must be decoded prior to the AD7874 evaluation board.

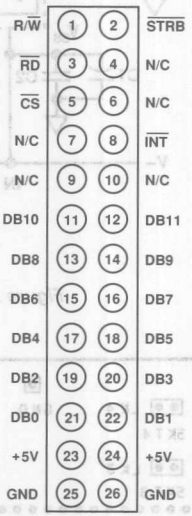

Figure 19. SKT8, IDC Connector Pinout

SKT1, SKT2, SKT3 and SKT4 provide the inputs for V_{IN1}, V_{IN2}, V_{IN3}, V_{IN4} respectively. Assuming LK1 to LK4 are in place, these input signals are fed to four buffer amplifiers, IC1, before being applied to the AD7874. The use of an external clock source is optional; there is a shorting plug (LK5) on the AD7874 CLK input which must be connected to either −5 V (for the ADCs own internal clock) or to SKT5. SKT6 and SKT7 provide the reference and $\overline{CONVST}$ inputs respectively. Shorting plug LK6 provides the option of using the external reference or the ADCs own internal reference.

POWER SUPPLY CONNECTIONS

The PCB requires two analog power supplies and one 5 V digital supply. The analog supplies are labeled V+ and V− and the range for both supplies is 12 V to 15 V (see silkscreen in Figure 23). Connection to the 5 V digital supply is made via SKT8. The +5 V supply and the −5 V supply required by the AD7874 are generated from voltage regulators (IC3 and IC4) on the V+ and V− supplies.

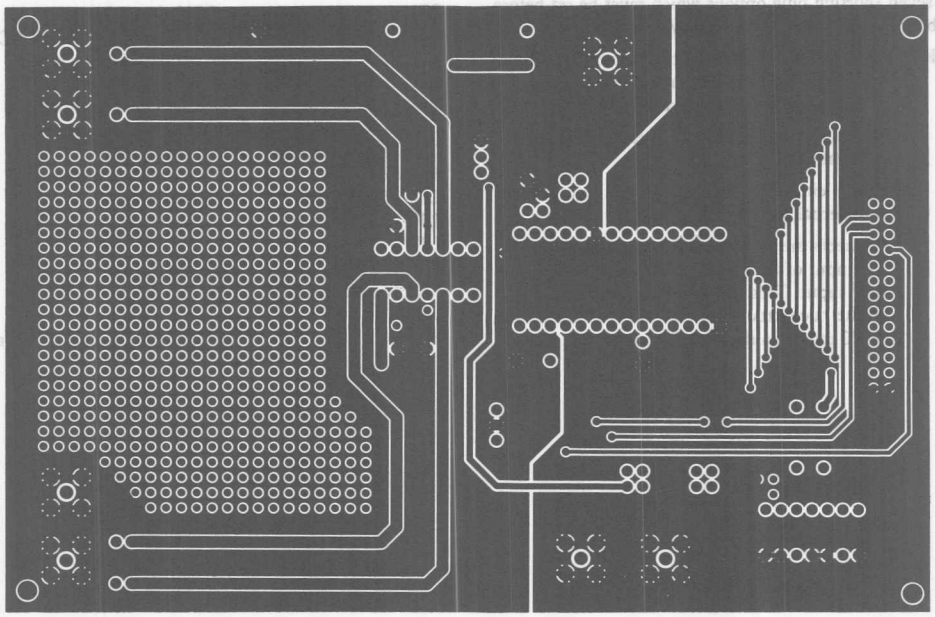

Figure 22. PCB Component Side Layout for the Circuit of Figure 20

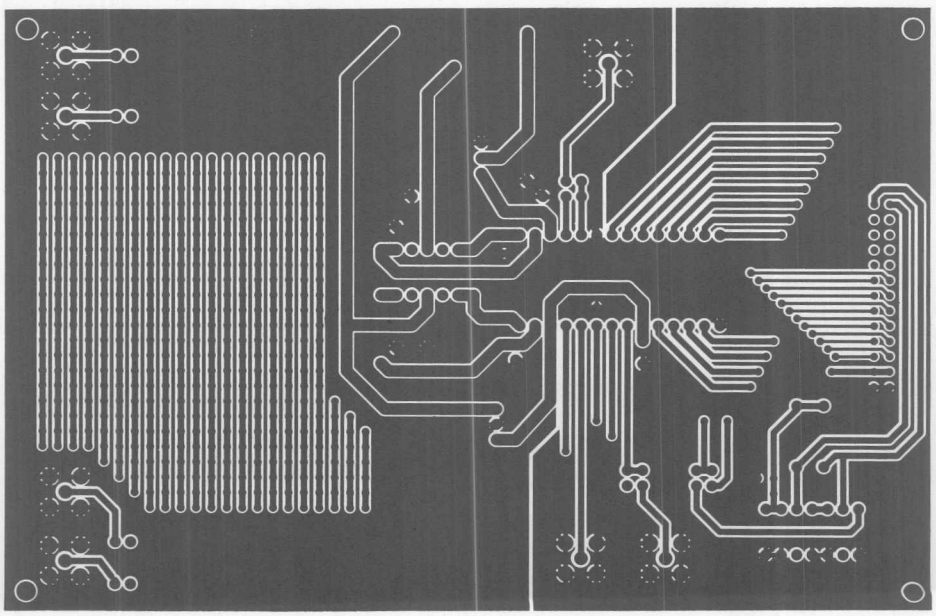

Figure 23. PCB Solder Side Layout for the Circuit of Figure 20

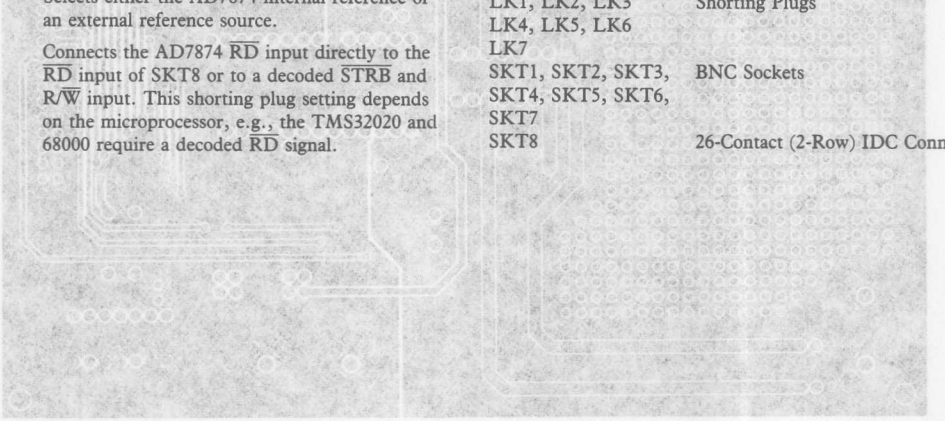
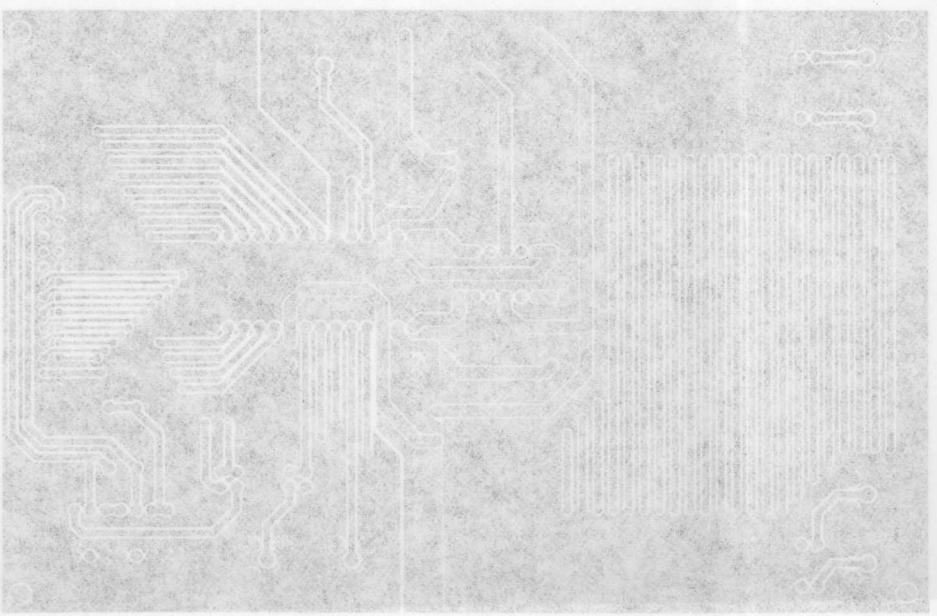


SHORTING PLUG OPTIONS



There are seven shorting plug options which must be set before using the board. These are outlined below:

LK1 – LK4	Connects the analog inputs to the buffer amplifiers. The analog inputs may also be connected to a component grid for signal conditioning.
LK5	Selects either the AD7874 internal clock or an external clock source.
LK6	Selects either the AD7874 internal reference or an external reference source.
LK7	Connects the AD7874 $\overline{RD}$ input directly to the $\overline{RD}$ input of SKT8 or to a decoded $\overline{STRB}$ and R/$\overline{W}$ input. This shorting plug setting depends on the microprocessor, e.g., the TMS32020 and 68000 require a decoded $\overline{RD}$ signal.

COMPONENT LIST

IC1	AD713 Quad Op Amp
IC2	AD7874 Analog-to-Digital Converter

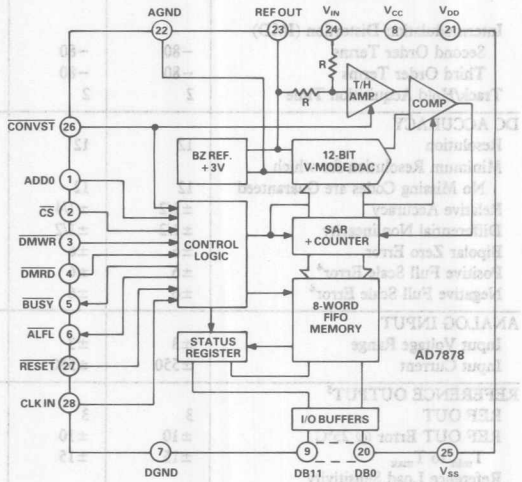
LC²MOS Complete 12-Bit 100 kHz Sampling ADC with DSP Interface

AD7878

2

FEATURES



Complete ADC with DSP Interface, Comprising:
- **Track/Hold Amplifier with 2 µs Acquisition Time**
- **7 µs A/D Converter**
- **3 V Zener Reference**
- **8-Word FIFO and Interface Logic**

72 dB SNR at 10 kHz Input Frequency
Interfaces to High Speed DSP Processors, e.g., ADSP-2100, TMS32010, TMS32020
41 ns max Data Access Time
Low Power, 60 mW typ

APPLICATIONS

Digital Signal Processing
Speech Recognition and Synthesis
Spectrum Analysis
High Speed Modems
DSP Servo Control

FUNCTIONAL BLOCK DIAGRAM

GENERAL DESCRIPTION

The AD7878 is a fast, complete 12-bit A/D converter with a versatile DSP interface consisting of an 8-word, first-in, first-out (FIFO) memory and associated control logic.

The FIFO memory allows up to eight samples to be digitized before the microprocessor is required to service the A/D converter. The eight words can then be read out of the FIFO at maximum microprocessor speed. A fast data access time of 41 ns allows direct interfacing to DSP processors and high speed 16-bit microprocessors.

An on-chip status/control register allows the user to program the effective length of the FIFO and contains the FIFO out of range, FIFO empty and FIFO word count information.

The analog input of the AD7878 has a bipolar range of ±3 V. The AD7878 can convert full power signals up to 50 kHz and is fully specified for dynamic parameters such as signal-to-noise ratio and harmonic distortion.

The AD7878 is fabricated in Linear Compatible CMOS (LC^2MOS), an advanced, mixed technology process that combines precision bipolar circuits with low power CMOS logic. The part is available in four package styles, 28-pin plastic and hermetic dual-in-line package (DIP), leadless ceramic chip carrier (LCCC) or plastic leaded chip carrier (PLCC).

PRODUCT HIGHLIGHTS

1. Complete A/D Function with DSP Interface
   The AD7878 provides the complete function for digitizing ac signals to 12-bit accuracy. The part features an on-chip track/hold, on-chip reference and 12-bit A/D converter. The additional feature of an 8-word FIFO reduces the high software overheads associated with servicing interrupts in DSP processors.
2. Dynamic Specifications for DSP Users
   The AD7878 is fully specified and tested for ac parameters, including signal-to-noise ratio, harmonic distortion and intermodulation distortion. Key digital timing parameters are also tested and specified over the full operating temperature range.
3. Fast Microprocessor Interface
   Data access time of 41 ns is the fastest ever achieved in a monolithic A/D converter and makes the AD7878 compatible with all modern 16-bit microprocessors and digital signal processors.

Parameter	J, A Versions[1]	K, L, B Versions	S Version	Units	Test Conditions/Comments
DYNAMIC PERFORMANCE[2]					
Signal-to-Noise Ratio (SNR)[3] @ 25°C	70	72	70	dB min	V_{IN} = 10 kHz Sine Wave , f_{SAMPLE} = 100 kHz
T_{min} to T_{max}	70	71	70	dB min	Typically 71.5 dB for 0<V_{IN}<50 kHz
Total Harmonic Distortion (THD)	−80	−80	−78	dB max	V_{IN} = 10 kHz Sine Wave, f_{SAMPLE} = 100 kHz Typically −86 dB for 0<V_{IN}<50 kHz
Peak Harmonic or Spurious Noise	−80	−80	−78	dB max	V_{IN} = 10 kHz, f_{SAMPLE} = 100 kHz Typically −86 dB for 0<V_{IN}<50 kHz

NOTES
[1]Timing Specifications in **bold** print are 100% production tested. All other times are sample tested at +25°C to ensure compliance. All input signals are specified with tr = tf = 5 ns (10% to 90% of 5 V) and timed from a voltage level of 1.6 V.
[2]t_9 and t_{14} are measured with the load circuits of Figure 1 and defined as the time required for an output to cross 0.8 V or 2.4 V.
[3]t_{10} is defined as the time required for the data lines to change 0.5 V when loaded with the circuits of Figure 2.

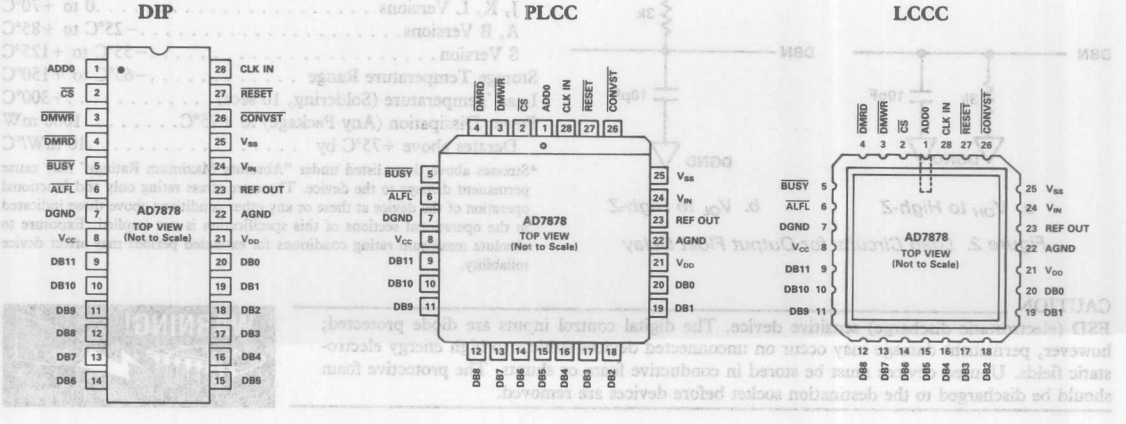
*Stresses above those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. These are stress rating only and functional operation of the device at these or any other conditions above those indicated in the operational sections of this specification is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

CAUTION



ESD (electrostatic discharge) sensitive device. The digital control inputs are diode protected; however, permanent damage may occur on unconnected devices subject to high energy electrostatic fields. Unused devices must be stored in conductive foam or shunts. The protective foam should be discharged to the destination socket before devices are removed.

PIN FUNCTION DESCRIPTION

Pin Number	Pin Mnemonic	Function
1	ADD0	Address Input. This control input determines whether the word placed on the output data bus during a read operation is a data word from the FIFO RAM or the contents of the status/control register. A logic low accesses the data word from Location 0 of the FIFO while a logic high selects the contents of the register (see Status/Control Register section).
2	$\overline{CS}$	Chip Select. Active low logic input. The device is selected when this input is active.
3	$\overline{DMWR}$	Data Memory Write. Active low logic input. $\overline{DMWR}$ is used in conjunction with $\overline{CS}$ low and ADD0 high to write data to the status/control register. Corresponds to $\overline{DMWR}$ (ADSP-2100), R/$\overline{W}$ (MC68000, TMS32020), $\overline{WE}$ (TMS32010).
4	$\overline{DMRD}$	Data Memory READ. Active low logic input. $\overline{DMRD}$ is used in conjunction with $\overline{CS}$ low to enable the three-state output buffers. Corresponds directly to $\overline{DMRD}$ (ADSP-2100), $\overline{DEN}$ (TMS32010).
5	$\overline{BUSY}$	Active low logic output. This output goes low when the ADC receives a $\overline{CONVST}$ pulse and remains low until the track/hold has gone into its hold mode. The three-state drivers of the AD7878 can be disabled while the $\overline{BUSY}$ signal is low (see Extended READ/WRITE section). This is achieved by writing a logic 0 to DB5 ($\overline{DISO}$) of the status/control register. Writing a logic 1 to DB5 of the status/control register allows data to be accessed from the AD7878 while $\overline{BUSY}$ is low.
6	$\overline{ALFL}$	FIFO Almost Full. A logic low indicates that the word count (i.e., number of conversion results) in the FIFO memory has reached the programmed word count in the status/control register. $\overline{ALFL}$ is updated at the end of each conversion. The $\overline{ALFL}$ output is reset to a logic high when a word is read from the FIFO memory and the word count is less than the preprogrammed word count. It can also be set high by writing a logic 1 to DB7 ($\overline{ENAF}$) of the status/control register.
7	DGND	Digital Ground. Ground reference for digital circuitry.
8	V_{CC}	Digital supply voltage, +5 V ±5%. Positive supply voltage for digital circuitry.
9	DB11	Data Bit 11 (MSB). Three-state TTL output. Coding for the data words in FIFO RAM is 2s complement.
10–15	DB10–DB5	Data Bit 10 to Data Bit 5. Three-state TTL input/outputs.
16–19	DB4–DB1	Data Bit 4 to Data Bit 1. Three-state TTL outputs.
20	DB0	Data Bit 0 (LSB). Three-state TTL output.
21	V_{DD}	Analog positive supply voltage, +5 V ±5%.
22	AGND	Analog Ground. Ground reference for track/hold, reference and DAC.
23	REF OUT	Voltage Reference Output. The internal 3 V analog reference is provided at this pin. The external load capability of the reference is 500 μA.
24	V_{IN}	Analog Input. Analog input range is ±3 V.
25	V_{SS}	Analog negative supply voltage, −5 V ±5%.
26	$\overline{CONVST}$	Convert Start. Logic input. A low to high transition on this input puts the track/hold into its hold mode and starts conversion. The $\overline{CONVST}$ input is asynchronous to CLK IN and is independent of $\overline{CS}$, $\overline{DMWR}$ and $\overline{DMRD}$.
27	$\overline{RESET}$	Reset. Active low logic input. A logic low sets the words in FIFO memory to 1000 0000 0000 and resets the $\overline{ALFL}$ output and status/control register.
28	CLK IN	Clock Input. TTL-compatible logic input. Used as the clock source for the A/D converter. The mark-space ratio of this clock can vary from 35/65 to 65/35.

STATUS/CONTROL REGISTER

The status/control register serves the dual function of providing control and monitoring the status of the FIFO memory. This register is directly accessible through the data bus (DB11–DB0) with a read or write operation while ADD0 is high. A write operation to the status/control register provides control for the $\overline{ALFL}$ output, bus interface and FIFO counter reset. This is normally done on power-up initialization. The FIFO memory address pointer is incremented after each conversion and compared with a preprogrammed count in the status/control register. When this preprogrammed count is reached, the $\overline{ALFL}$ output is asserted if the $\overline{ENAF}$ control bit is set to zero. This $\overline{ALFL}$ can be used to interrupt the microprocessor after any predetermined number of conversions (between 1 and 8). The status of the address pointer along with sample overrange and $\overline{ALFL}$ status can be accessed at any time by reading the status/control register. Note, reading the status/control register does not cause any internal data movement in the FIFO memory. Status information for a particular word should be read from the status register before the data word is read from the FIFO memory.

STATUS/CONTROL REGISTER FUNCTION DESCRIPTION

DB11 ($\overline{ALFL}$)

Almost Full Flag, Read only. This is the same as Pin 6 ($\overline{ALFL}$ output) status. A logic low indicates that the word count in the FIFO memory has reached the preprogrammed count in bit locations DB10–DB8. $\overline{ALFL}$ is updated at the end of conversion.

DB10–DB8 (AFC2–AFC0)

Almost Full Word Count, Read/Write. The count value determines the number of words in the FIFO memory which will cause $\overline{ALFL}$ to be set. When the FIFO word count equals the programmed count in these three bits, then both the $\overline{ALFL}$ output and DB11 of the status register are set to a logic low. For example, when a code of 011 is written to these bits, $\overline{ALFL}$ is set when Location 0 through Location 3 of the FIFO memory contains valid data. AFC2 is the most significant bit of the word count. The count value can be read back if required.

DB7 ($\overline{ENAF}$)

Enable Almost Full, Read/Write. Writing a 1 to this bit disables the $\overline{ALFL}$ output and status register bit DB11.

DB6 (FOVR/RESET)

FIFO Overrun/RESET, Read/Write. Reading a 1 from this bit indicates that at least one sample has been discarded because the FIFO memory is full. When the FIFO is full (i.e., contains eight words) any further conversion results will be lost. Writing a 1 to this bit causes a system RESET as per the $\overline{RESET}$ input (Pin 27).

DB5 (FOOR/$\overline{DISO}$)

FIFO Out of RANGE/Disable Outputs, Read/Write. Reading a 1 from this bit indicates that at least one sample in the FIFO memory is out of range. Writing a 0 to this bit prevents the data bus from becoming active while $\overline{BUSY}$ is low, regardless of the state of $\overline{CS}$ and $\overline{DMRD}$.

DB4 (FEMP)

FIFO Empty, Read Only. Reading a 1 indicates that there are no samples in the FIFO memory. When the FIFO is empty the internal ripple-down effects of the FIFO are disabled and further reads will continue to access the last valid data word in Location 0.

DB3 (SOOR)

Sample out of Range, Read Only. Reading a 1 indicates that the next sample to be read is out of range, i.e., the sample in Location 0 of the FIFO.

DB2–DB0 (FCN2–FCN0)

FIFO Word Count, Read Only. The value read from these bits indicates the number of samples in the FIFO memory. For example, reading 011 from these bits indicates that Location 0 through Location 3 contains valid data. Note, reading all 0s indicates that there is either one word or no word in the FIFO memory; in this case the FIFO Empty determines if there is no word in memory. FCN2 is the most significant bit.

Table I. Status/Control Bit Function Description

BIT LOCATION	DB11	DB10	DB9	DB8	DB7	DB6	DB5	DB4	DB3	DB2	DB1	DB0
STATUS INFORMATION (READ)	$\overline{ALFL}$	AFC2	AFC1	AFC0	$\overline{ENAF}$	FOVR	FOOR	FEMP	SOOR	FCN2	FCN1	FCN0

RESET STATUS	1	0	0	0	0	0	0	1	0	0	0	0

X =DON'T CARE

memory locations. Each word in memory contains 13 bits of information - 12 bits of data from the conversion result and one additional bit which contains information as to whether the 12-bit result is out of range or not. A block diagram of the AD7878 FIFO architecture is shown in Figure 3.

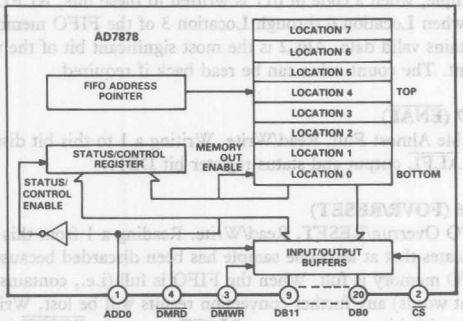

Figure 3. Internal FIFO Architecture

The conversion result is gathered in the successive approximation register (SAR) during conversion. At the end of conversion this result is transferred to the FIFO memory. The FIFO address pointer always points to the top of memory, which is the uppermost location containing valid data. The pointer is incremented after each conversion. A read operation from the FIFO memory accesses data from the bottom of the FIFO, Location 0. On completion of the read operation, each data word moves down one location and the address pointer is decremented by one. Therefore, each conversion result from the SAR enters at the top of memory, propagates down with successive reads until it reaches Location 0 from where it can be accessed by a microprocessor read operation.

The transfer of information from the SAR to the FIFO occurs in synchronization with the AD7878 input clock (CLK IN). The propagation of data words down the FIFO is also synchronous with this clock. As a result, a read operation to obtain data from the FIFO must also be synchronous with CLK IN to avoid Read/Write conflicts in the FIFO (i.e., reading from FIFO Location 0 while it is being updated). This requires that the microprocessor clock and the AD7878 CLK IN are derived from the same source.

INTERNAL COMPARATOR TIMING

The ADC clock, which is applied to CLK IN, controls the successive approximation A/D conversion process. This clock is internally divided by four to yield a bit trial cycle time of 500 ns latched by the rising edge of an internal comparator strobe signal. There are 12 bit decisions, as in a normal successive approximation routine, and one extra decision that checks if the input sample is out of range. In a normal successive approximation A/D converter, reading data from the device during conversion can upset the conversion in progress. This is due to on-chip transients, generated by charging or discharging the data bus, concurrent with a bit decision. The scheme outlined below and shown in Figure 4 describes how the AD7878 overcomes this problem.

The internal comparator strobe on the AD7878 is gated with both $\overline{\text{DMRD}}$ and $\overline{\text{DMWR}}$ so that if a read or write operation occurs when a bit decision is about to be made, the bit decision point is deferred by one CLK IN cycle. In other words, if $\overline{\text{DMRD}}$ or $\overline{\text{DMWR}}$ goes low (with $\overline{\text{CS}}$ low) at any time during the CLK IN low-time immediately prior to the comparator strobing edge (t_{LOW} of Figure 4), the bit trial is suspended for a clock cycle. This makes sure that the bit decision is latched at a time when the AD7878 is not attempting to charge or discharge the data bus, thereby ensuring that no spurious transients occur internally near a bit decision point.

The decision point slippage mechanism is shown in Figure 4 for the MSB decision. Normally, the MSB decision occurs 25 ns after the fourth rising CLK IN edge after $\overline{\text{CONVST}}$ goes high. However, in the timing diagram of Figure 4, $\overline{\text{CS}}$ and $\overline{\text{DMRD}}$ or $\overline{\text{DMWR}}$ are low in the time period t_{LOW} prior to the MSB decision point on the fourth rising edge. This causes the internal comparator strobe to be slipped to the fifth rising clock edge. The AD7878 will again check during a period t_{LOW} prior to this fifth rising clock edge; and if the $\overline{\text{CS}}$ and $\overline{\text{DMRD}}$ or $\overline{\text{DMWR}}$ are still low, the bit decision point will be slipped a further clock cycle.

The conversion time for the ADC normally consists of the 13-bit trials described above and one extra internal clock cycle during which data is written from the SAR to the FIFO. For an 8 MHz input clock this results in a conversion time of 7 μs. However, the software routine servicing the AD7878 has the potential to read 16 times from the device during conversion – 8 reads from the FIFO and 8 reads from the status/control register. It also has the potential to write once to the status/control register. If these 17 (16 read plus 1 write) operations all occur during t_{LOW} time periods, the conversion time will slip by 17 CLK IN cycles. Therefore, if read or write operations can occur during t_{LOW} periods, it means that the conversion time for the ADC can vary from 7 μs to 9.12 μs (assuming 8 MHz CLK IN). This calculation assumes that there is a slippage of one CLK IN cycle for each read or write operation.

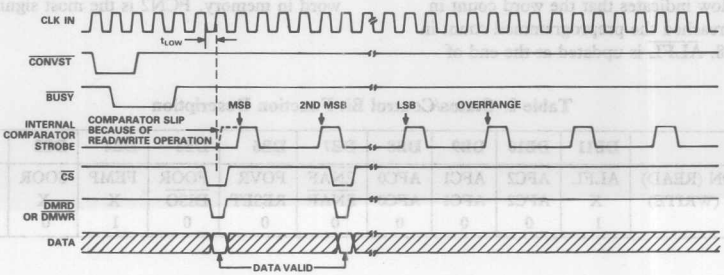

Figure 4. Operational Timing Diagram

INITIATING A CONVERSION

Conversion is initiated on the AD7878 by asserting the $\overline{\text{CONVST}}$ input. This $\overline{\text{CONVST}}$ input is an asynchronous input independent of either the ADC or DSP clocks. This is essential for applications where precise sampling in time is important. In these applications the signal sampling must occur at exactly equal intervals to minimize errors due to sampling uncertainty or jitter. In these cases the $\overline{\text{CONVST}}$ input is driven from a timer or some precise clock source. On receipt of a $\overline{\text{CONVST}}$ pulse, the AD7878 acknowledges by taking the $\overline{\text{BUSY}}$ output low. This $\overline{\text{BUSY}}$ output can be used to ensure no bus activity while the track/hold goes from track to hold mode (see Extended Read-/Write section). The $\overline{\text{CONVST}}$ input must stay low for at least two CLK IN periods. The track/hold amplifier switches from the track to hold mode on the rising edge of $\overline{\text{CONVST}}$ and conversion is also initiated at this point. The $\overline{\text{BUSY}}$ output returns high after the $\overline{\text{CONVST}}$ input goes high and the ADC begins its successive approximation routine. Once conversion has been initiated another conversion start should not be attempted until the full conversion cycle has been completed. Figure 5 shows the timing diagram for the conversion start.

In applications where precise sampling is not critical, the $\overline{\text{CONVST}}$ pulse can be generated from a microprocessor $\overline{\text{WR}}$ or $\overline{\text{RD}}$ line gated with a decoded address (different to the AD7878 $\overline{\text{CS}}$ address). Note that the $\overline{\text{CONVST}}$ pulse width must be a minimum of two AD7878 CLK IN cycles.

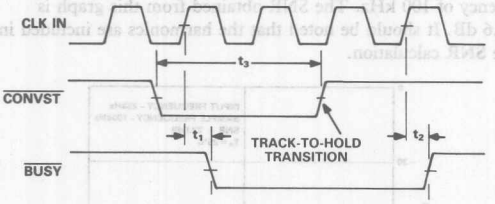

Figure 5. Conversion Start Timing Diagram

READ/WRITE OPERATIONS

The AD7878 read/write operations consist of reading from the FIFO memory and reading and writing from the status/control register. These operations are controlled by the $\overline{\text{CS}}$, $\overline{\text{DMRD}}$, $\overline{\text{DMWR}}$ and ADD0 logic inputs. A description of these operations is given in the following sections. In addition to the basic read/write operations there is an extended read/write operation. This can occur if a read/write operation occurs during a $\overline{\text{CONVST}}$ pulse. This extended read/write is intended for use with microprocessors that can be driven into a WAIT state, and the scheme is recommended for applications where an external timer controls the $\overline{\text{CONVST}}$ input asynchronously to the microprocessor read/write operations.

Basic Read Operation

Figure 6 shows the timing diagram for a basic read operation on the AD7878. $\overline{\text{CS}}$ and $\overline{\text{DMRD}}$ going low accesses data from either the status/control register or the FIFO memory. A read operation with ADD0 low accesses data from the FIFO while a read with ADD0 high accesses data from the status/control register.

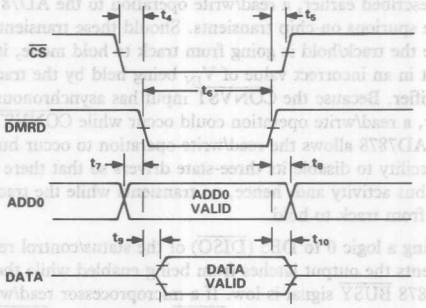

Figure 6. Basic Read Operation

Basic Write Operation

A basic write operation to the AD7878 status/control register consists of bringing $\overline{\text{CS}}$ and $\overline{\text{DMWR}}$ low with ADD0 high. Internally these signals are gated with CLK IN to provide an internal REGISTER ENABLE signal (see Figure 7). The pulse width of this REGISTER ENABLE signal is effectively the overlap between the CLK IN low time and the $\overline{\text{DMWR}}$ pulse. This may result in shorter write pulse widths, data setup times and data hold times than those given by the microprocessor. The timing on the AD7878 timing diagram of Figure 8 is therefore given with respect to the internal REGISTER ENABLE signal rather than the $\overline{\text{DMWR}}$ signal.

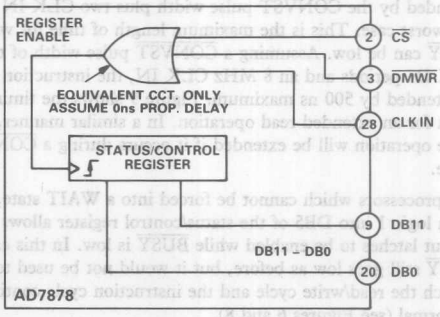

Figure 7. $\overline{\text{DMWR}}$ Internal Logic

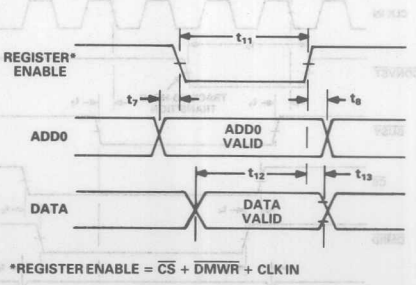

Figure 8. Basic Write Operation

Extended Read/Write Operation

As described earlier, a read/write operation to the AD7878 can cause spurious on-chip transients. Should these transients occur while the track/hold is going from track to hold mode, it may result in an incorrect value of V_{IN} being held by the track/hold amplifier. Because the $\overline{CONVST}$ input has asynchronous capability, a read/write operation could occur while $\overline{CONVST}$ is low. The AD7878 allows the read/write operation to occur but has the facility to disable its three-state drivers so that there is no data bus activity and, hence, no transients while the track/hold goes from track to hold.

Writing a logic 0 to DB5 ($\overline{DISO}$) of the status/control register prevents the output latches from being enabled while the AD7878 $\overline{BUSY}$ signal is low. If a microprocessor read/write operation can occur during the $\overline{BUSY}$ low time, the $\overline{BUSY}$ should be gated with $\overline{CS}$ of the AD7878 and this gated signal used to stretch the instruction cycle using DMACK (ADSP-2100), READY (TMS32020) or $\overline{DTACK}$ (68000).

When $\overline{CONVST}$ goes low, the AD7878 acknowledges it by bringing $\overline{BUSY}$ low on the next rising edge of CLK IN. With a logic 0 in DB5, the AD7878 data bus cannot now be enabled. If a read/write operation now occurs, the $\overline{BUSY}$ and $\overline{CS}$ gated signal drives the microprocessor into a WAIT state, thereby extending the read/write operation. $\overline{BUSY}$ goes high on the second rising edge of CLK IN after $\overline{CONVST}$ goes high. The AD7878 data outputs are now enabled and the microprocessor is released from its WAIT state, allowing it to complete its read/write operation to the AD7878.

The microprocessor cycle time for the read/write operation is extended by the $\overline{CONVST}$ pulse width plus two CLK IN periods worst case. This is the maximum length of time for which $\overline{BUSY}$ can be low. Assuming a $\overline{CONVST}$ pulse width of two CLK IN periods and an 8 MHz CLK IN, the instruction cycle is extended by 500 ns maximum. Figure 9 shows the timing diagram for an extended read operation. In a similar manner, a write operation will be extended if it occurs during a $\overline{CONVST}$ pulse.

For processors which cannot be forced into a WAIT state, writing a logic 1 into DB5 of the status/control register allows the output latches to be enabled while $\overline{BUSY}$ is low. In this case $\overline{BUSY}$ still goes low as before, but it would not be used to stretch the read/write cycle and the instruction cycle continues as normal (see Figures 6 and 8).

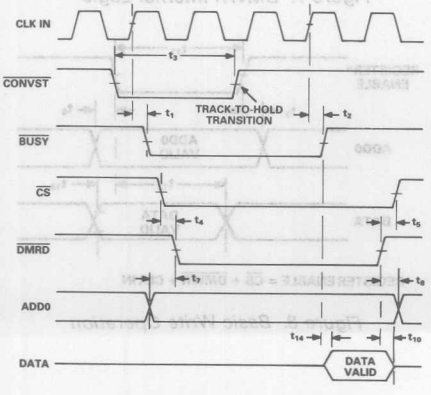

Figure 9. Extended Read Operation

AD7878 DYNAMIC SPECIFICATIONS

The AD7878 is specified and 100% tested for dynamic performance specifications rather than for traditional dc specifications such as Integral and Differential Nonlinearity. These ac specifications provide information on the AD7878's effect on the spectral content of the input signal. Hence, the parameters for which the AD7878 is specified include SNR, Harmonic Distortion, Intermodulation Distortion and Peak Harmonics. These terms are discussed in more detail in the following sections.

Signal-to-Noise Ratio (SNR)

SNR is the measured signal-to-noise ratio at the output of the ADC. The signal is the rms magnitude of the fundamental. Noise is the rms sum of all the nonfundamental signals (excluding dc) up to half the sampling frequency (fs/2). SNR is dependent upon the number of quantization levels used in the digitization process; the more levels, the smaller the quantization noise. The theoretical signal-to-noise ratio for a sine wave input is given by

$$SNR = (6.02\,N + 1.76)\,dB \quad \ldots\ldots\ldots\ldots\ldots\ldots (1)$$

where N is the number of bits. Thus for an ideal 12-bit converter, SNR = 74 dB.

The output spectrum from the ADC is evaluated by applying a sine-wave signal of very low distortion to the V_{IN} input, which is sampled at a 100 kHz sampling rate. A Fast Fourier Transform (FFT) plot is generated from which the SNR data can be obtained. Figure 10 shows a typical 2048 point FFT plot of the AD7878KN with an input signal of 25 kHz and a sampling frequency of 100 kHz. The SNR obtained from this graph is 72.6 dB. It should be noted that the harmonics are included in the SNR calculation.

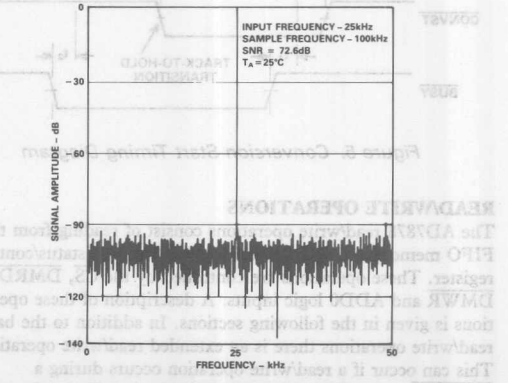

Figure 10. AD7878 FFT Plot

Effective Number of Bits

The formula given in (1) relates the SNR to the number of bits. Rewriting the formula, as in (2), it is possible to get a measure of performance expressed in effective number of bits (N). The effective number of bits for a device can be calculated directly from its measured SNR.

$$N = \frac{SNR - 1.76}{6.02} \quad \ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots (2)$$

Figure 11 shows a typical plot of effective number of bits versus frequency for an AD7878KN with a sampling frequency of 100 kHz. The effective number of bits typically falls between 11.7 and 11.85 corresponding to SNR figures of 72.2 and 73.1 dB.

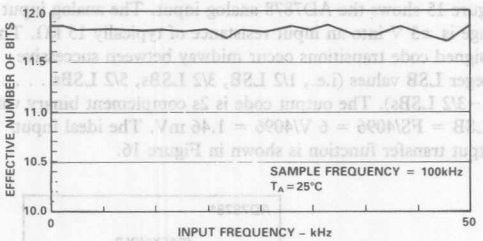

Figure 11. Effective Number of Bits vs. Frequency

Harmonic Distortion

Harmonic Distortion is the ratio of the rms sum of harmonics to the fundamental. For the AD7878, Total Harmonic Distortion (THD) is defined as:

$$THD = 20\ Log \frac{\sqrt{(V_2^2 + V_3^2 + V_4^2 + V_5^2 + V_6^2)}}{V_1}$$

where V_1 is the rms amplitude of the fundamental and V_2, V_3, V_4, V_5 and V_6 are the rms amplitudes of the second to the sixth harmonic. The THD is also derived from the FFT plot of the ADC output spectrum.

Intermodulation Distortion

With inputs consisting of sine waves at two frequencies, fa and fb, any active device with nonlinearities will create distortion products at sum and difference frequencies of mfa±nfb where m, n = 0,1,2,3 . . . . , etc. Intermodulation terms are those for which neither m nor n is equal to zero. For example, the second order terms include (fa+fb) and (fa−fb) while the third order terms include (2fa+fb), (2fa−fb), (fa+2fb) and (fa−2fb).

Using the CCIF standard, where two input frequencies near the top end of the input bandwidth are used, the second and third order terms are of different significance. The second order terms are usually distanced in frequency from the original sine waves, while the third order terms are usually at a frequency close to the input frequencies. As a result, the second and third order terms are specified separately. The calculation of the intermodulation distortion is as per the THD specification where it is the ratio of the rms sum of the individual distortion products to the rms amplitude of the fundamental expressed in dBs.

Intermodulation distortion is calculated using an FFT algorithm but, in this case, the input consists of two equal amplitude, low distortion sine waves. Figure 12 shows a typical IMD plot for the AD7878.

Peak Harmonic or Spurious Noise

Peak harmonic or spurious noise is defined as the ratio of the rms value of the next largest component in the ADC output spectrum (up to fs/2 and excluding dc) to the rms value of the fundamental. Normally, the value of this specification will be determined by the largest harmonic in the spectrum, but for parts where the harmonics are buried in the noise floor the largest peak will be a noise peak.

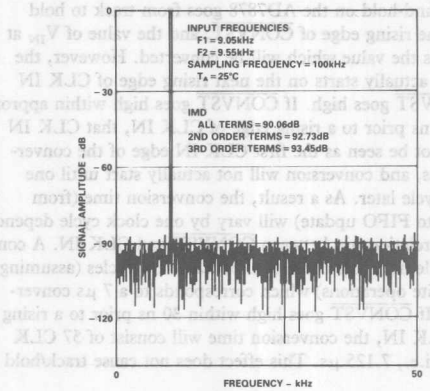

Figure 12. AD7878 IMD Plot

Histogram Plot

When a sine wave of a specified frequency is applied to the V_{IN} input of the AD7878 and several million samples are taken, it is possible to plot a histogram showing the frequency of occurrence of each of the 4096 ADC codes. If a particular step is wider than the ideal 1 LSB width, then the code associated with that step will accumulate more counts than for the code for an ideal step. Likewise, a step narrower than ideal will have fewer counts. Missing codes are easily seen in the histogram plot because a missing code means zero counts for a particular code. Large spikes in the plot indicate large differential nonlinearity.

Figure 13 shows a histogram plot for the AD7878KN with a sampling frequency of 100 kHz and an input frequency of 25 kHz. For a sine-wave input, a perfect ADC would produce a cusp probability density function described by the equation:

$$p\ (V) = \frac{1}{\pi\sqrt{(A^2 - V^2)}}$$

where A is the peak amplitude of the sine wave and p (V) is the probability of occurrence at a voltage V. The histogram plot of Figure 13 corresponds very well with this cusp shape. The absence of large spikes in this plot indicates small dynamic differential nonlinearity (the largest spike in the plot represents less than 1/4 LSB of DNL error). The AD7878 has no missing codes under these conditions since no code records zero counts.

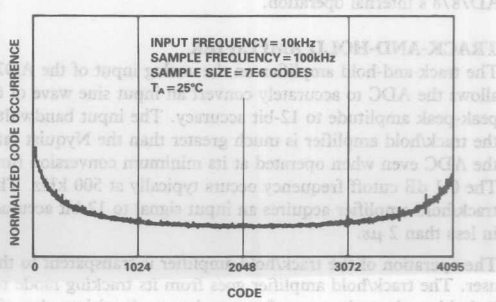

Figure 13. AD7878 Histogram Plot

mode on the rising edge of $\overline{\text{CONVST}}$, and the value of V_{IN} at this point is the value which will be converted. However, the conversion actually starts on the next rising edge of CLK IN after $\overline{\text{CONVST}}$ goes high. If $\overline{\text{CONVST}}$ goes high within approximately 30 ns prior to a rising edge of CLK IN, that CLK IN edge will not be seen as the first CLK IN edge of the conversion process, and conversion will not actually start until one CLK IN cycle later. As a result, the conversion time (from $\overline{\text{CONVST}}$ to FIFO update) will vary by one clock cycle depending on the relationship between $\overline{\text{CONVST}}$ and CLK IN. A conversion cycle normally consists of 56 CLK IN cycles (assuming no read/write operations) which corresponds to a 7 μs conversion time. If $\overline{\text{CONVST}}$ goes high within 30 ns prior to a rising edge of CLK IN, the conversion time will consist of 57 CLK IN cycles, i.e., 7.125 μs. This effect does not cause track/hold jitter.

INTERNAL REFERENCE

The AD7878 has an on-chip temperature compensated buried Zener reference (see Figure 14) that is factory trimmed to 3 V ±1%. Internally, it provides both the DAC reference and the dc bias required for bipolar operation. The reference output is available (REF OUT) and is capable of providing up to 500 μA to an external load.

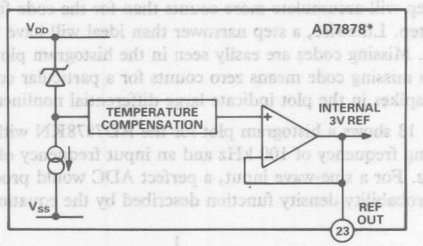

Figure 14. AD7878 Reference Circuit

The maximum recommended capacitance on REF OUT for normal operation is 50 pF. If the reference is required for use external to the AD7878, then it should be decoupled with a 200 Ω resistor in series with a parallel combination of a 10 μF tantalum capacitor and a 0.1 μF ceramic capacitor. These decoupling components are required to remove voltage spikes caused by the AD7878's internal operation.

TRACK-AND-HOLD AMPLIFIER

The track-and-hold amplifier on the analog input of the AD7878 allows the ADC to accurately convert an input sine wave of 6 V peak-peak amplitude to 12-bit accuracy. The input bandwidth of the track/hold amplifier is much greater than the Nyquist rate of the ADC even when operated at its minimum conversion time. The 0.1 dB cutoff frequency occurs typically at 500 kHz. The track/hold amplifier acquires an input signal to 12-bit accuracy in less than 2 μs.

The operation of the track/hold amplifier is transparent to the user. The track/hold amplifier goes from its tracking mode to its hold mode at the start of conversion on the rising edge of $\overline{\text{CONVST}}$ and returns to track mode at the end of conversion.

range is ±3 V into an input resistance of typically 15 kΩ. The designed code transitions occur midway between successive integer LSB values (i.e., 1/2 LSB, 3/2 LSBs, 5/2 LSBs . . . . FS−3/2 LSBs). The output code is 2s complement binary with 1 LSB = FS/4096 = 6 V/4096 = 1.46 mV. The ideal input/output transfer function is shown in Figure 16.

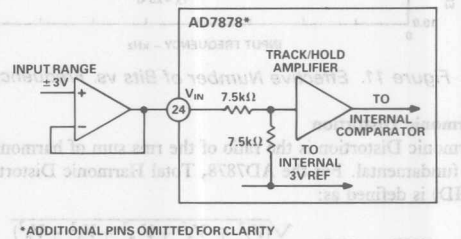

Figure 15. AD7878 Analog Input

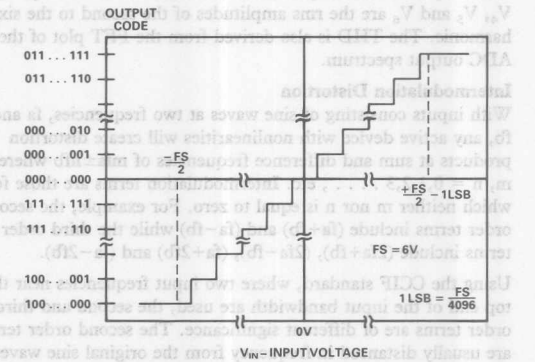

Figure 16. Input/Output Transfer Function

OFFSET AND FULL-SCALE ADJUSTMENT

In most Digital Signal Processing (DSP) applications offset and full-scale error have little or no effect on system performance. Offset error can always be eliminated in the analog domain by ac coupling. Full-scale error effect is linear and does not cause problems as long as the input signal is within the full dynamic range of the ADC. Some applications may require that the input signal span the full analog input dynamic range and, accordingly, offset and full-scale error will have to be adjusted to zero.

Where adjustment is required, offset must be adjusted before full-scale error. This is achieved by trimming the offset of the op amp driving the analog input of the AD7878 while the input voltage is 1/2 LSB below ground. The trim procedure is as follows: apply a voltage of −0.73 mV (−1/2 LSB) at V_1 and adjust the op amp offset voltage until the ADC output code flickers between 1111 1111 1111 and 0000 0000 0000.

Gain error can be adjusted at either the first code transition (ADC negative full scale) or the last code transition (ADC positive full scale). The trim procedures for both cases are as follows:

Positive Full-Scale Adjust

Apply a voltage of 2.9978 V (FS/2 − 3/2 LSBs) at V_1. Adjust

R2 until the ADC output code flickers between 0111 1111 1110 and 0111 1111 1111.

Negative Full-Scale Adjust

Apply a voltage of −2.9993 V (−FS/2 + 1/2 LSB) at V_1 and adjust R2 until the ADC output code flickers between 1000 0000 0000 and 1000 0000 0001.

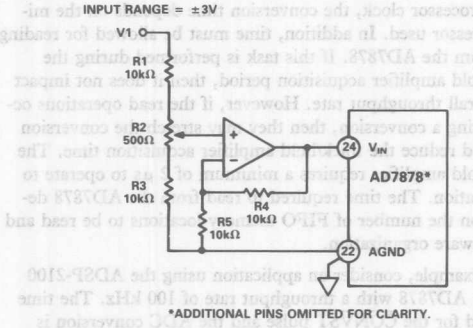

Figure 17. AD7878 Full-Scale Adjust Circuit

MICROPROCESSOR INTERFACING

The AD7878 high speed bus timing allows direct interfacing to DSP processors. Due to the complexity of the AD7878 internal logic, only synchronous interfacing is allowed. This means that the ADC clock must be the same as, or a derivative of, the processor clock. Suitable processor interfaces are shown in Figures 18 to 21.

AD7878–ADSP-2100/TMS32010/TMS32020

All three interfaces use an external timer for conversion control, allowing the ADC to sample the analog input asynchronously to the microprocessor. The AD7878 $\overline{ALFL}$ output interrupts the processor when the FIFO preprogrammed word count is reached. The processor then reads the conversion results from the AD7878 internal FIFO memory.

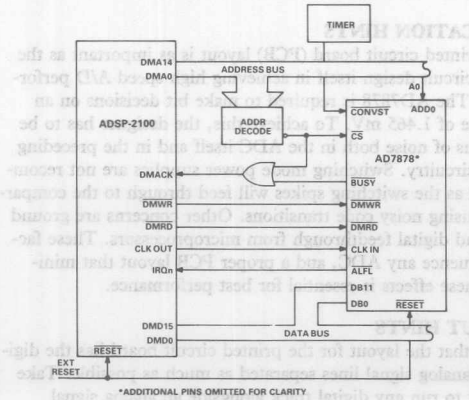

Figure 18. AD7878–ADSP-2100 Interface

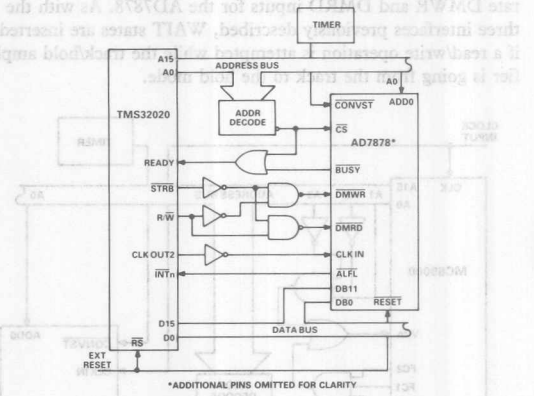

Figure 19. AD7878 – TMS32020 Interface

The interfaces to the ADSP-2100 and the TMS32020 gate the AD7878 $\overline{CS}$ and the $\overline{BUSY}$ to provide a signal which drives the processor into a wait state if a read/write operation to the ADC is attempted while the ADC track/hold amplifier is going from the track to the hold mode. This avoids digital feedthrough to the analog circuitry. The TMS32020 does not have separate $\overline{RD}$ and $\overline{WR}$ outputs to drive the AD7878 $\overline{DMWR}$ and $\overline{DMRD}$ inputs. These are generated from the processor $\overline{STRB}$ and R/$\overline{W}$ outputs with the addition of some logic gates.

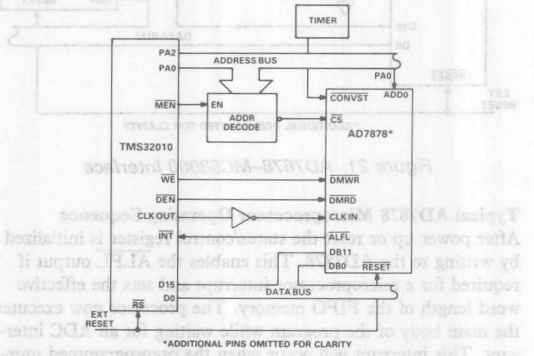

Figure 20. AD7878 – TMS32010 Interface

AD7878–MC68000

This interface also uses an external timer for conversion control as described for the previous three interfaces. It is discussed separately because it needs extra logic due to the nature of its interrupts. The MC68000 has eight levels of external interrupt. When interrupting this processor one of these levels (0 to 7) has to be encoded onto the $\overline{IPL2}$–$\overline{IPL0}$ inputs. This is achieved with a 74148 encoder in Figure 21, (interrupt Level 1 is taken for example purposes only). The MC68000 places this interrupt level on address bits A3 to A1 at the start of the interrupt service routine. Additional logic is used to decode this interrupt level on the address bus and the FC2–FC0 outputs to generate a $\overline{VPA}$ signal for the MC68000. This results in an autovectored interrupt, the start address for the service routine must be loaded into the appropriate auto vector location during initialization. For further information on the 68000 interrupts consult the 68000 user's manual.

The MC68000 $\overline{AS}$ and R/$\overline{W}$ outputs are used to generate separate $\overline{DMWR}$ and $\overline{DMRD}$ inputs for the AD7878. As with the three interfaces previously described, WAIT states are inserted if a read/write operation is attempted while the track/hold amplifier is going from the track to the hold mode.

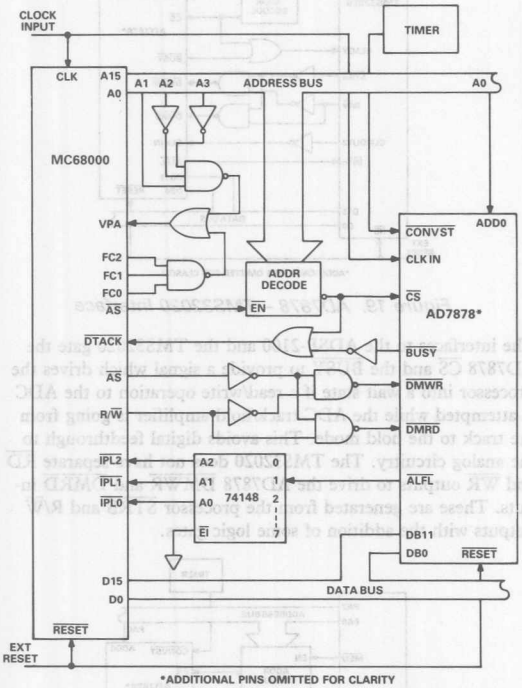

Figure 21. AD7878–MC68000 Interface

Typical AD7878 Microprocessor Operating Sequence

After power up or reset the status/control register is initialized by writing to the AD7878. This enables the $\overline{ALFL}$ output if required for a microprocessor interrupt and sets the effective word length of the FIFO memory. The processor now executes the main body of the program while waiting for an ADC interrupt. This interrupt will occur when the preprogrammed number of samples are collected in the FIFO memory. The interrupt service routine first interrogates DB5(FOOR) of the status/control register to determine if any sample in the FIFO memory is out of range. If all data samples are valid, then the program proceeds to read the FIFO memory. If, on the other hand, at least one sample is out of range, then an overrange routine is called.

There are many actions that can be taken by the out of range routine, the selection of which is application dependent. One option is to ignore all the current samples residing in the FIFO memory, reinitialize the status/control register and return to the main body of the program. Another option is to check the individual out of range status of each word in the FIFO memory and to discard the invalid ones. The underrange or overrange status of each word can also be determined and the analog input adjusted accordingly before returning to the main program.

Note there is no need to check the out of range status if the analog input is always assured to be within range.

THROUGHPUT RATE

The AD7878 has a maximum specified throughput rate (sample rate) of 100 kHz. This is a worst-case test condition and specifications apply for reduced sampling rates, provided that the Nyquist criterion is obeyed. The throughput rate must take into account ADC $\overline{CONVST}$ pulse width, ADC conversion time and the track/hold amplifier acquisition time. The time required for each of these tasks is shown in Table II for a selection of DSP processors. Since the ADC clock has to be synchronized to the microprocessor clock, the conversion time depends on the microprocessor used. In addition, time must be allowed for reading data from the AD7878. If this task is performed during the track/hold amplifier acquisition period, then it does not impact the overall throughput rate. However, if the read operations occur during a conversion, then they may stretch the conversion time and reduce the track/hold amplifier acquisition time. The track/hold amplifier requires a minimum of 2 μs to operate to specification. The time required to read from the AD7878 depends on the number of FIFO memory locations to be read and the software organization.

As an example, consider an application using the ADSP-2100 and the AD7878 with a throughput rate of 100 kHz. The time required for the $\overline{CONVST}$ pulse and the ADC conversion is 7.375 μs. This leaves 2.625 μs for the track/hold acquisition time and for reading the ADC (both operations occurring in parallel). The ADSP-2100, when operating from a 32 MHz clock, has an instruction cycle of 125 ns and an interrupt response time of 500 ns. This allows adequate time to perform 16 read operations within the time budget allowed.

Table II. AD7878 Throughput Rate

	$\overline{CONVST}$ Pulse Width	Conversion Time	T/H Acquisition Time
Number of Clock Cycles	2 min	57 max	Non-Applicable
ADSP-2100[1]	250 ns min	7.125 μs max	2 μs min
TMS32010[2]	400 ns min	11.14 μs max	2 μs min
TMS32020[2]	400 ns min	11.14 μs max	2 μs min

NOTES
[1]ADSP-2100 Clock Freq. = 32 MHz.
[2]TMS320XX Clock Freq. = 20 MHz.

APPLICATION HINTS

Good printed circuit board (PCB) layout is as important as the overall circuit design itself in achieving high speed A/D performance. The AD7878 is required to make bit decisions on an LSB size of 1.465 mV. To achieve this, the designer has to be conscious of noise both in the ADC itself and in the preceding analog circuitry. Switching mode power supplies are not recommended as the switching spikes will feed through to the comparator, causing noisy code transitions. Other concerns are ground loops and digital feedthrough from microprocessors. These factors influence any ADC, and a proper PCB layout that minimizes these effects is essential for best performance.

LAYOUT HINTS

Ensure that the layout for the printed circuit board has the digital and analog signal lines separated as much as possible. Take care not to run any digital track alongside an analog signal track. Guard (screen) the analog input with AGND.

Establish a single point analog ground (star ground) separate from the logic system ground at Pin 22 (AGND) or as close as possible to the AD7878, as shown in Figure 22. Connect all other grounds and Pin 7 (AD7878 DGND) to this single analog ground point. Do not connect any other digital grounds to this analog ground point. Low impedance analog and digital power supply common returns are essential to low noise operation of the ADC, so make the foil width for these tracks as wide as possible. The use of ground planes minimizes impedance paths and also guards the analog circuitry from digital noise. The circuit layouts of Figures 25 and 26 have both analog and digital ground planes, which are kept separated and only joined together at the AD7878 AGND pin.

NOISE

Keep the input signal leads to V_{IN} and signal return leads from AGND (Pin 22) as short as possible to minimize input noise coupling. In applications where this is not possible, use a shielded cable between the source and the ADC. Reduce the ground circuit impedance as much as possible since any potential difference in grounds between the signal source and the ADC appears as an error voltage in series with the input signal.

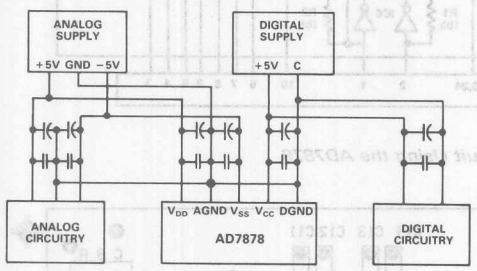

Figure 22. Power Supply Grounding Practice

DATA ACQUISITION BOARD

Figure 23 shows the AD7878 in a data acquisition circuit that will interface directly to either the ADSP-2100, TMS32010 or the TMS32020. The corresponding printed circuit board (PCB) layout and silkscreen are shown in Figures 24 to 26.

The only additional component required for a full data acquisition system is an antialiasing filter. There is a component grid provided near the analog input on the PCB which may be used for such a filter or any other conditioning circuitry. To facilitate this option, a wire link (labelled LK1 on the PCB) is required on the analog input track. This link connects the input signal to either the component grid or directly to the buffer amplifier driving the AD7878 analog input.

Microprocessor connections to the PCB can be made by either of two ways:

1. 96-contact (3 ROW) Eurocard connector.
2. 26-contact (2 ROW) IDC connector.

The 96-contact Eurocard connector is directly compatible with the ADSP-2100 Evaluation Board Prototype Expansion Connector. The expansion connector on the ADSP-2100 has eight decoded chip enable outputs labelled $\overline{ECE8}$ to $\overline{ECE1}$. $\overline{ECE6}$ is used to drive the AD7878 $\overline{CS}$ input on the data acquisition board. To avoid selecting onboard RAM sockets at the same time, LK6 on the ADSP-2100 board must be removed. In addition, the expansion connector on the ADSP-2100 has four interrupts labelled $\overline{EIRQ3}$ to $\overline{EIRQ0}$. The AD7878 $\overline{ALFL}$ output connects to $\overline{EIRQ0}$. The AD7878 and ADSP-2100 data lines are aligned for left justified data transfer.

The 26-way IDC connector contains all the necessary contacts for both the TMS32010 and TMS32020. There are two switches on the data acquisition board that must be set to enable the appropriate interface configuration (see Table III). The interface connections for the TMS32010/32020 and IDC signal contact numbers are shown in Table IV and Figure 23. Note the AD7878 $\overline{CS}$ input must be decoded from the address bus prior to the AD7878 evaluation board for the TMS320XX interfaces.

Connections to the analog input (V_{IN}) and the $\overline{CONVST}$ input are made via two BNC sockets labelled SKT1 and SKT2 on the silk-screen. If the $\overline{CONVST}$ input is derived from either the microprocessor or ADC clock, the effects of clock noise coupling will be reduced.

POWER SUPPLY CONNECTIONS

The PCB requires two analog supplies and one 5 V digital supply. Connections to the analog supplies are made directly to the PCB as shown on the silk screen in Figure 24. The connections are labelled V+ and V− and the range for both of these supplies is 12 V to 15 V. Connection to the 5 V digital supply is made through either of the two microprocessor connectors. The +5 V and −5 V analog power supplies required by the AD7878 are generated from two voltage regulators on the V+ and V− power supply inputs (IC3 and IC4 in Figure 23).

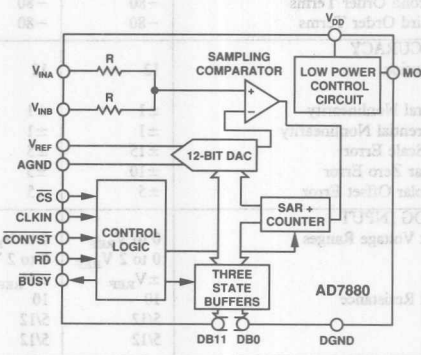
LC²MOS, Single +5 V Supply, Low Power, 12-Bit Sampling ADC

AD7880



FEATURES

12-Bit Monolithic A/D Converter
66 kHz Throughput Rate
12 μs Conversion Time
3 μs On-Chip Track/Hold Amplifier
Low Power
Power Save Mode: 2 mW typ
Normal Operation: 25 mW typ
70 dB SNR
Fast Data Access Time: 57 ns
Small 24-Lead SOIC and 0.3" DIP Packages

APPLICATIONS

Battery Powered Portable Systems
Digital Signal Processing
Speech Recognition and Synthesis
High Speed Modems
Control and Instrumentation

FUNCTIONAL BLOCK DIAGRAM

GENERAL DESCRIPTION

The AD7880 is a high speed, low power, 12-bit A/D converter which operates from a single +5 V supply. It consists of a 3 μs track/hold amplifier, a 12 μs successive-approximation ADC, versatile interface logic and a multiple-input-range circuit. The part also includes a power save feature.

An internal resistor network allows the part to accept both unipolar and bipolar input signals while operating from a single +5 V supply. Fast bus access times and standard control inputs ensure easy interfacing to modern microprocessors and digital signal processors.

The AD7880 features a total throughput time of 15 μs and can convert full power signals up to 33 kHz with a sampling frequency of 66 kHz.

In addition to the traditional dc accuracy specifications such as linearity, full-scale and offset errors, the AD7880 is also fully specified for dynamic performance parameters including harmonic distortion and signal-to-noise ratio.

The AD7880 is fabricated in Analog Devices' Linear Compatible CMOS (LC²MOS) process, a mixed technology process that combines precision bipolar circuits with low power CMOS logic. The part is available in a 24-pin, 0.3 inch-wide, plastic or hermetic dual-in-line package (DIP) as well as a small 24-lead SOIC package.

PRODUCT HIGHLIGHTS

1. Fast Conversion Time.
   12 μs conversion time and 3 μs acquisition time allow for large input signal bandwidth. This performance is ideally suited for applications in areas such as telecommunications, audio, sonar and radar signal processing.
2. Low Power Consumption.
   2 mW power consumption in the power-down mode makes the part ideally suited for portable, hand held, battery powered applications.
3. Multiple Input Ranges.
   The part features three user-determined input ranges, 0 to +5 V, 0 to 10 V and ±5 V. These unipolar and bipolar ranges are achieved with a 5 V only power supply.

AD7880—SPECIFICATIONS

(V_{DD} = +5 V ± 5%, V_{REF} = V_{DD}, AGND = DGND = 0 V, f_{CLKIN} = 2.5 MHz, MODE = V_{DD} unless otherwise noted. All Specifications T_{min} to T_{max} unless otherwise noted.)

t_8[3]	5	5	ns min	Bus Relinquish Time after $\overline{RD}$
	50	50	ns max	

NOTES

[1]Timing specifications in **bold** print are 100% production tested. All other times are sample tested at 25°C to ensure compliance. All input signals are specified with tr = tf = 5 ns (10% to 90% of 5 V) and timed from a voltage level of 1.6 V.

[2]t_7 is measured with the load circuit of Figure 2 and defined as the time required for an output to cross 0.8 V or 2.4 V.

[3]t_8 is derived from the measured time taken by the data outputs to change by 0.5 V when loaded with the circuit of Figure 2. The measured number is then extrapolated back to remove the effects of charging the 50 pF capacitor. This means that the time, t_8, quoted in the timing characteristics is the true bus relinquish time of the part and as such is independent of external bus loading capacitances.

*Stresses above those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. This is a stress rating only and functional operation of the device at these or any other conditions above those listed in the operational sections of this specification is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

CAUTION

ESD (electrostatic discharge) sensitive device. The digital control inputs are diode protected; however, permanent damage may occur on unconnected devices subject to high energy electrostatic fields. Unused devices must be stored in conductive foam or shunts. The protective foam should be discharged to the destination socket before devices are removed.

PIN CONFIGURATION

PIN FUNCTION DESCRIPTION

Pin No.	Pin Mnemonic	Function
1	V_{INA}	Analog Input.
2	V_{INB}	Analog Input.
3	AGND	Analog Ground.
4	V_{REF}	Voltage Reference Input. This is normally tied to V_{DD}.
5	$\overline{CS}$	Chip Select. Active Low Logic input. The device is selected when this input is active.
6	$\overline{CONVST}$	Convert Start. A low to high transition on this input puts the track/hold into hold mode and starts conversion. This input is asynchronous to the CLKIN and is independent of $\overline{CS}$ and $\overline{RD}$.
7	$\overline{RD}$	Read. Active Low Logic Input. This input is used in conjunction with $\overline{CS}$ low to enable data outputs.
8	$\overline{BUSY}$	Active Low Logic Output. This status line indicates converter status. $\overline{BUSY}$ is low during conversion.
9	CLKIN	Clock Input. TTL-compatible logic input. Used as the clock source for the A/D converter. The mark/space ratio of the clock can vary from 40/60 to 60/40.
10	DGND	Digital Ground.
11 . . . 22	DB0–DB11	Three-State Data Outputs. These become active when $\overline{CS}$ and $\overline{RD}$ are brought low.
23	MODE	MODE Input. This input is used to put the device into the power save mode (MODE = 0 V). During normal operation, the MODE input will be a logic high (MODE = V_{DD}).
24	V_{DD}	Power Supply. This is nominally +5 V.

CIRCUIT INFORMATION

The AD7880 is a +5 V single supply 12-bit A/D converter. The part requires no external components apart from a 2.5 MHz external clock and power supply decoupling capacitors. It contains a 12-bit successive approximation ADC based on a fast-settling voltage-output DAC, a high speed comparator and SAR, as well as the necessary control logic. The charge balancing comparator used in the AD7880 provides the user with an inherent track-and-hold function. The ADC is specified to work with sampling rates up to 66 kHz.

CONVERTER DETAILS

The AD7880 conversion cycle is initiated on the rising edge of the $\overline{CONVST}$ pulse, as shown in the timing diagram of Figure 1. The rising edge of the $\overline{CONVST}$ pulse places the track/hold amplifier into "HOLD" mode. The conversion cycle then takes between 26 and 28 clock periods. The maximum specified conversion time is 12 μs. This corresponds to a conversion cycle time of 28 clock periods with a CLKIN frequency of 2.5 MHz and also includes internal propagation delays. During conversion the $\overline{BUSY}$ output will remain low, and the output databus drivers will be three-stated. When a conversion is completed, the $\overline{BUSY}$ output will go to a high level, and the result of the conversion can be read by bringing $\overline{CS}$ and $\overline{RD}$ low.

The track/hold amplifier acquires a 12-bit input signal in 3 μs. The overall throughput time for the AD7880 is equal to the conversion time plus the track/hold acquisition time. For a 2.5 MHz input clock the throughput time is 15 μs.

REFERENCE INPUT

For specified performance, it is recommended that the reference input be tied to V_{DD}. The part, however, will operate with a reference down to 2.5 V though with reduced performance specifications. Figure 3 shows a graph of signal-to-noise ratio (SNR) versus V_{REF}.

V_{REF} must not be allowed to go above V_{DD} by more than 100 mV.

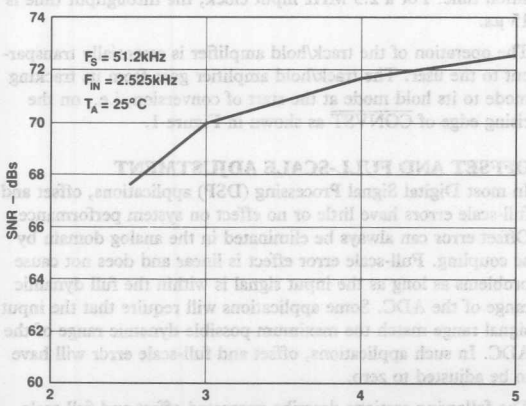

Figure 3. SNR Versus V_{REF}

ANALOG INPUT

The AD7880 has two analog input pins, V_{INA} and V_{INB}. Figure 4 shows the input circuitry to the ADC sampling comparator. The on-board attenuator network, made up of equal resistors, allows for various input ranges.

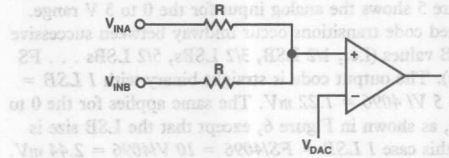

Figure 4. AD7880 Input Circuit

The AD7880 accommodates three separate input ranges, 0 to V_{REF}, 0 to 2 V_{REF} and $\pm V_{REF}$. The input configurations corresponding to these ranges are shown in Figures 5, 6 and 7.

With $V_{REF} = V_{DD}$ and using a nominal V_{DD} of +5 V, the input ranges are 0 to 5 V, 0 to 10 V and ±5 V, as shown in Table II.

Table II. Analog Input Ranges

Analog Input Range	V_{REF}	Input Connections		Connection Diagram
		V_{INA}	V_{INB}

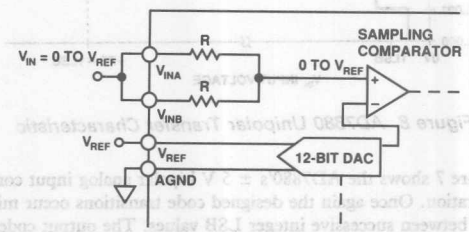

Figure 5. 0 to V_{REF} Unipolar Input Configuration

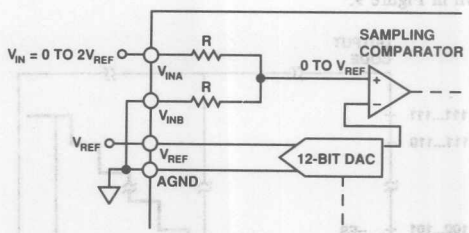

Figure 6. 0 to 2 V_{REF} Unipolar Input Configuration

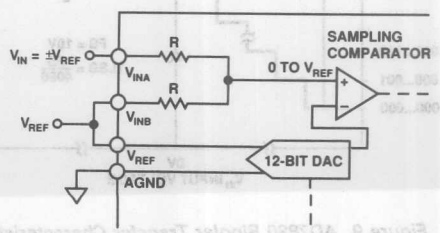

Figure 7. ±V_{REF} Bipolar Input Configuration

The AD7880 has two unipolar input ranges, 0 to 5 V and 0 to 10 V. Figure 5 shows the analog input for the 0 to 5 V range. The designed code transitions occur midway between successive integer LSB values (i.e., 1/2 LSB, 3/2 LSBs, 5/2 LSBs . . . FS −3/2 LSBs). The output code is straight binary with *1 LSB = FS/4096 = 5 V/ 4096 = 1.22 mV*. The same applies for the 0 to 10 V range, as shown in Figure 6, except that the LSB size is bigger. In this case *1 LSB = FS/4096 = 10 V/4096 = 2.44 mV*. The ideal input/output transfer characteristic for both these unipolar ranges is shown in Figure 8.

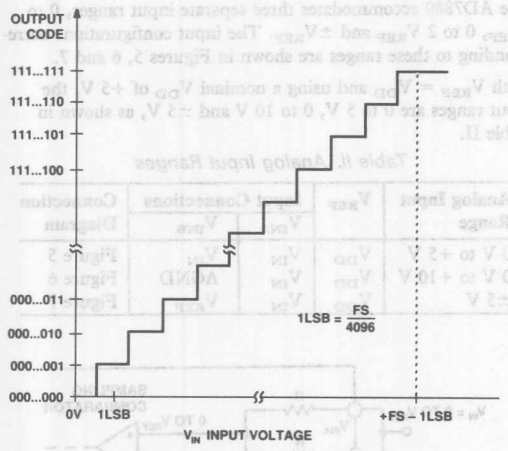

Figure 8. AD7880 Unipolar Transfer Characteristic

Figure 7 shows the AD7880's ± 5 V bipolar analog input configuration. Once again the designed code transitions occur midway between successive integer LSB values. The output code is straight binary with *1 LSB = FS/4096 = 10 V/4096 = 2.44 mV*. The ideal bipolar input/output transfer characteristic is shown in Figure 9.

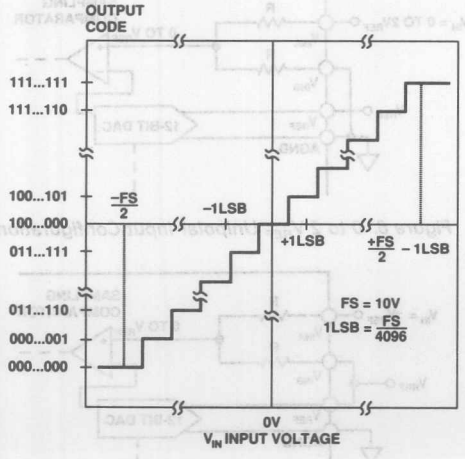

Figure 9. AD7880 Bipolar Transfer Characteristic

CLOCK INPUT

The AD7880 is specified to operate with a 2.5 MHz clock connected to the CLKIN input pin. This pin may be driven directly by CMOS or TTL buffers. The mark/space ratio on the clock can vary from 40/60 to 60/40. As the clock frequency is slowed down, it can result in slightly degraded accuracy performance. This is due to leakage effects on the hold capacitor in the internal track-and-hold amplifier. Figure 10 is a typical plot of accuracy versus clock frequency for the ADC.

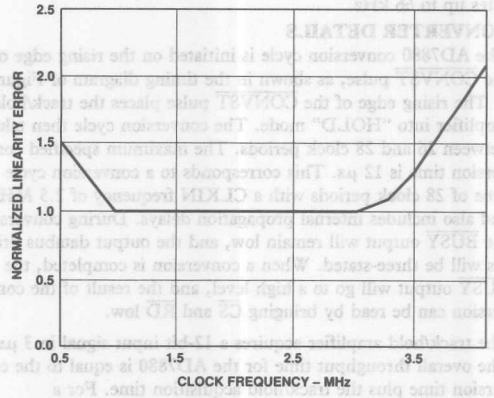

Figure 10. Normalized Linearity Error vs. Clock Frequency

TRACK/HOLD AMPLIFIER

The charge balanced comparator used in the AD7880 for the A/D conversion provides the user with an inherent track/hold function. The track/hold amplifier acquires an input signal to 12-bit accuracy in less than 3 μs. The overall throughput time is equal to the conversion time plus the track/hold amplifier acquisition time. For a 2.5 MHz input clock, the throughput time is 15 μs.

The operation of the track/hold amplifier is essentially transparent to the user. The track/hold amplifier goes from its tracking mode to its hold mode at the start of conversion, i.e., on the rising edge of $\overline{\text{CONVST}}$ as shown in Figure 1.

OFFSET AND FULL-SCALE ADJUSTMENT

In most Digital Signal Processing (DSP) applications, offset and full-scale errors have little or no effect on system performance. Offset error can always be eliminated in the analog domain by ac coupling. Full-scale error effect is linear and does not cause problems as long as the input signal is within the full dynamic range of the ADC. Some applications will require that the input signal range match the maximum possible dynamic range of the ADC. In such applications, offset and full-scale error will have to be adjusted to zero.

The following sections describe suggested offset and full-scale adjustment techniques which rely on adjusting the inherent offset of the op amp driving the input to the ADC as well as tweaking an additional external potentiometer as shown in Figure 11.

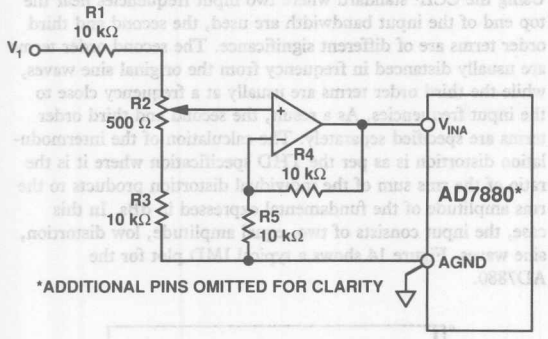

Figure 11. Offset and Full-Scale Adjust Circuit

Unipolar Adjustments

In the case of the 0 to 5 V unipolar input configuration, unipolar offset error must be adjusted before full-scale error. Adjustment is achieved by trimming the offset of the op amp driving the analog input of the AD7880. This is done by applying an input voltage of 0.61 mV (1/2 LSB) to V_1 in Figure 11 and adjusting the op amp offset voltage until the ADC output code flickers between 0000 0000 0000 and 0000 0000 0001. For full-scale adjustment, an input voltage of 4.9982 V (FS−3/2 LSBs) is applied to V_1 and R2 is adjusted until the output code flickers between 1111 1111 1110 and 111 1111 1111.

The same procedure is required for the 0 to 10 V input configuration of Figure 6. An input voltage of 1.22 mV (1/2 LSB) is applied to V_1 in Figure 11 and the op amp's offset voltage is adjusted until the ADC output code flickers between 0000 0000 0000 and 0000 0000 0001. For full-scale adjustment, an input voltage of 9.9963 V (FS−3/2 LSBs) is applied to V_1 and R2 is adjusted until the output code flickers between 1111 1111 1110 and 111 1111 1111.

Bipolar Adjustments

Bipolar zero and full-scale errors for the bipolar input configuration of Figure 7 are adjusted in a similar fashion to the unipolar case. Again, bipolar zero error must be adjusted before full-scale error. Bipolar zero error adjustment is achieved by trimming the offset of the op amp driving the analog input of the AD7880 while the input voltage is 1/2 LSB below ground. This is done by applying an input voltage of −1.22 mV (1/2 LSB) to V_1 in Figure 11 and adjusting the op amp offset voltage until the ADC output code flickers between 0111 1111 1111 and 1000 0000 0000. For full-scale adjustment, an input voltage of 4.9982 V(FS/2-3/2 LSBs) is applied to V1 and R2 is adjusted until the output code flickers between 1111 1111 1110 and 1111 1111 1111.

DYNAMIC SPECIFICATIONS

The AD7880 is specified and tested for dynamic performance specifications as well as traditional dc specifications such as integral and differential nonlinearity. The ac specifications are required for signal processing applications such as speech recognition, spectrum analysis and high speed modems. These applications require information on the ADC's effect on the spectral content of the input signal. Hence, the parameters for which the AD7880 is specified include SNR, harmonic distortion, intermodulation distortion and peak harmonics. These terms are discussed in more detail in the following sections.

Signal-to-Noise Ratio (SNR)

SNR is the measured signal-to-noise ratio at the output of the ADC. The signal is the rms magnitude of the fundamental. Noise is the rms sum of all the nonfundamental signals up to half the sampling frequency (FS/2) excluding dc. SNR is dependent upon the number of quantization levels used in the digitization process; the more levels, the smaller the quantization noise. The theoretical signal to noise ratio for a sine wave input is given by:

$$SNR = (6.02\ N + 1.76)\ dB \qquad (1)$$

where N is the number of bits.

Thus for an ideal 12-bit converter, SNR = 74 dB.

The output spectrum from the ADC is evaluated by applying a sine wave signal of very low distortion to the V_{IN} input which is sampled at a 66 kHz sampling rate. A Fast Fourier Transform (FFT) plot is generated from which the SNR data can be obtained. Figure 12 shows a typical 2048 point FFT plot of the AD7880 with an input signal of 2.5 kHz and a sampling frequency of 61 kHz. The SNR obtained from this graph is 73 dB. It should be noted that the harmonics are taken into account when calculating the SNR.

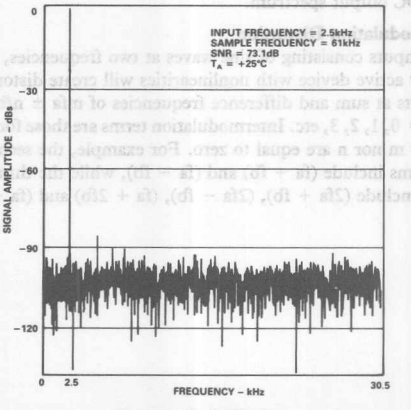

Figure 12. FFT Plot

Effective Number of Bits

The formula given in Equation 1 relates the SNR to the number of bits. Rewriting the formula, as in Equation 2, it is possible to get a measure of performance expressed in effective number of bits (N).

$$N = \frac{SNR - 1.76}{6.02} \qquad (2)$$

The effective number of bits for a device can be calculated directly from its measured SNR.

Figure 13 shows a plot of effective number of bits versus input frequency for an AD7880 with a sampling frequency of 61 kHz. The effective number of bits typically remains better than 11.5 for frequencies up to 12 kHz.

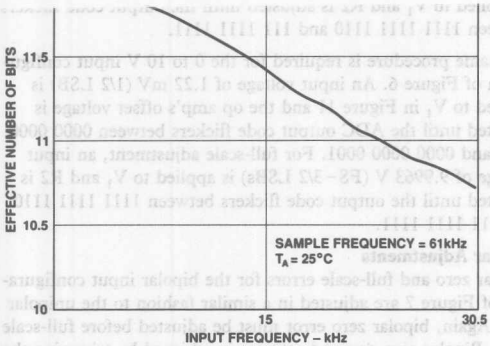

Figure 13. Effective Number of Bits vs. Frequency

Total Harmonic Distortion (THD)

THD is the ratio of the rms sum of harmonics to the rms value of the fundamental. For the AD7880, THD is defined as:

$$THD = 20 \log \frac{\sqrt{V_2^2 + V_3^2 + V_4^2 + V_5^2 + V_6^2}}{V_1} \quad (3)$$

where V_1 is the rms amplitude of the fundamental and V_2, V_3, V_4, V_5 and V_6 are the rms amplitudes of the second through the sixth harmonic. The THD is also derived from the FFT plot of the ADC output spectrum.

Intermodulation Distortion

With inputs consisting of sine waves at two frequencies, fa and fb, any active device with nonlinearities will create distortion products at sum and difference frequencies of mfa ± nfb where m, n = 0, 1, 2, 3, etc. Intermodulation terms are those for which neither m nor n are equal to zero. For example, the second order terms include (fa + fb) and (fa − fb), while the third order terms include (2fa + fb), (2fa − fb), (fa + 2fb) and (fa − 2fb).

top end of the input bandwidth are used, the second and third order terms are of different significance. The second order terms are usually distanced in frequency from the original sine waves, while the third order terms are usually at a frequency close to the input frequencies. As a result, the second and third order terms are specified separately. The calculation of the intermodulation distortion is as per the THD specification where it is the ratio of the rms sum of the individual distortion products to the rms amplitude of the fundamental expressed in dBs. In this case, the input consists of two, equal amplitude, low distortion, sine waves. Figure 14 shows a typical IMD plot for the AD7880.

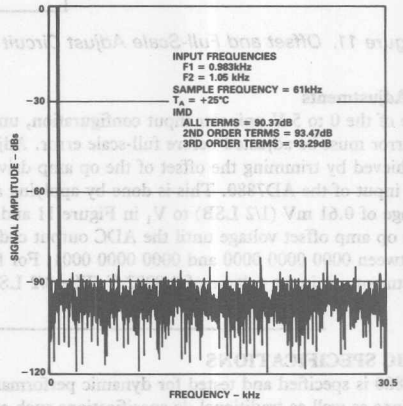

Figure 14. IMD Plot

Peak Harmonic or Spurious Noise

Peak harmonic or spurious noise is defined as the ratio of the rms value of the next largest component in the ADC output spectrum (up to FS/2 and excluding dc) to the rms value of the fundamental. Normally, the value of this specification will be determined by the largest harmonic in the spectrum, but for parts where the harmonics are buried in the noise floor the peak will be a noise peak.

MICROPROCESSOR INTERFACING

The AD7880 high speed bus timing allows direct interfacing to real time digital signal processors, DSPs, as well as modern high speed, 16-bit microprocessors. Suitable microprocessor interfaces are shown in Figures 15 through 20.

AD7880–ADSP-2100 Interface

Figure 15 shows an interface between the AD7880 and the ADSP-2100. Conversion is initiated using a timer to drive the $\overline{\text{CONVST}}$ input asynchronously to the microprocessor. This allows very accurate control of the sampling instant. When conversion is complete, the AD7880 $\overline{\text{BUSY}}$ line goes high. An inverter on this $\overline{\text{BUSY}}$ output drives the $\overline{\text{IRQ}}$ line low thus providing an interrupt to the ADSP-2100 when conversion is completed. The conversion result is then read from the AD7880 into the ADSP-2100 with the following instruction:

MR0 = DM(ADC)

where *MR0* is the ADSP-2100 MR0 Register and
ADC is the AD7880 address.

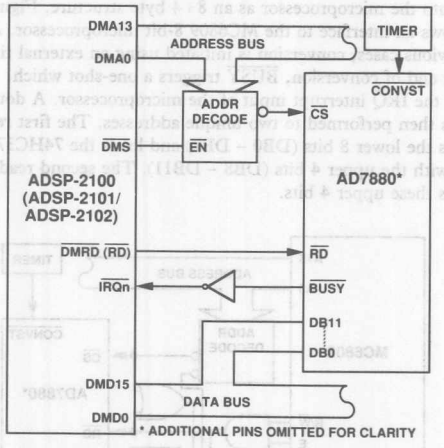

Figure 15. AD7880–ADSP-2100 (ADSP-2101/ADSP-2102) Interface

AD7880–ADSP-2101/ADSP-2102 Interface

The interface outlined in Figure 15 also forms the basis for an interface between the AD7880 and the ADSP-2101/ADSP-2102. The READ line of the ADSP-2101/ADSP-2102 is labeled $\overline{\text{RD}}$. In this interface, the $\overline{\text{RD}}$ pulse width of the processor can be programmed using the Data Memory Wait State Control Register. The instruction used to read a conversion result is as outlined for the ADSP-2100.

AD7880-TMS32010 Interface

An interface between the AD7880 and the TMS32010 is shown in Figure 16. Once again the conversion is initiated using an external timer and the TMS32010 is interrupted when conversion is completed. The following instruction is used to read the conversion result from the AD7880:

IN D,ADC

where *D* is Data Memory Address and
ADC is the AD7880 address.

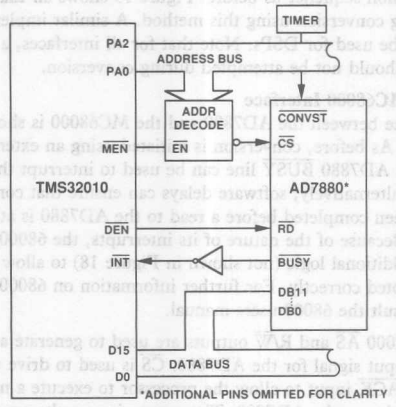

Figure 16. AD7880–TMS32010 Interface

AD7880–TMS320C25 Interface

Figure 17 shows an interface between the AD7880 and the TMS320C25. As with the two previous interfaces, conversion is initiated with a timer, and the processor is interrupted when the conversion sequence is completed. The TMS320C25 does not have a separate $\overline{\text{RD}}$ output to drive the AD7880 $\overline{\text{RD}}$ input directly. This has to be generated from the processor $\overline{\text{STRB}}$ and R/$\overline{\text{W}}$ outputs with the addition of some logic gates. The $\overline{\text{RD}}$ signal is OR-gated with the $\overline{\text{MSC}}$ signal to provide the one WAIT state required in the read cycle for correct interface timing. Conversion results are read from the AD7880 using the following instruction:

IN D,ADC

where *D* is Data Memory Address and
ADC is the AD7880 address.

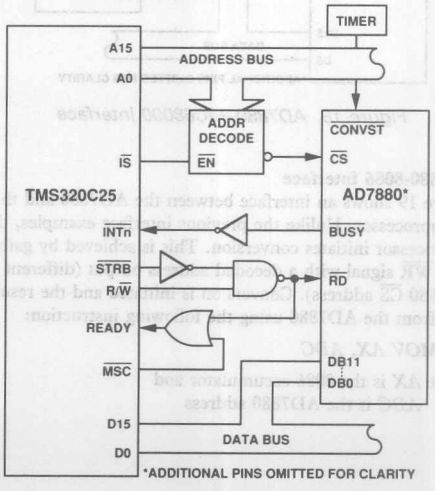

Figure 17. AD7880–TMS320C25 Interface

Some applications may require that the conversion be initiated by the microprocessor rather than an external timer. One option is to decode the AD7880 $\overline{\text{CONVST}}$ from the address bus so that

a write operation starts a conversion. Data is read at the end of the conversion sequence as before. Figure 19 shows an example of initiating conversion using this method. A similar implementation can be used for DSPs. Note that for all interfaces, a read operation should not be attempted during conversion.

AD7880–MC68000 Interface

An interface between the AD7880 and the MC68000 is shown in Figure 18. As before, conversion is initiated using an external timer. The AD7880 $\overline{BUSY}$ line can be used to interrupt the processor or, alternatively, software delays can ensure that conversion has been completed before a read to the AD7880 is attempted. Because of the nature of its interrupts, the 68000 requires additional logic (not shown in Figure 18) to allow it to be interrupted correctly. For further information on 68000 interrupts, consult the 68000 users manual.

The MC68000 $\overline{AS}$ and R/$\overline{W}$ outputs are used to generate a separate $\overline{RD}$ input signal for the AD7880. $\overline{CS}$ is used to drive the 68000 $\overline{DTACK}$ input to allow the processor to execute a normal read operation to the AD7880. The conversion results are read using the following 68000 instruction:

MOVE.W ADC, D0

where *D0* is the 68000 D0 register and
ADC is the AD7880 address

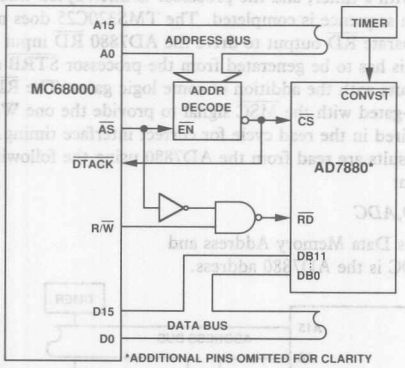

Figure 18. AD7880–MC68000 Interface

AD7880-8086 Interface

Figure 19 shows an interface between the AD7880 and the 8086 microprocessor. Unlike the previous interface examples, the microprocessor initiates conversion. This is achieved by gating the 8086 $\overline{WR}$ signal with a decoded address output (different to the AD7880 $\overline{CS}$ address). Conversion is initiated and the result is read from the AD7880 using the following instruction:

MOV AX, ADC

where *AX* is the 8086 accumulator and
ADC is the AD7880 address

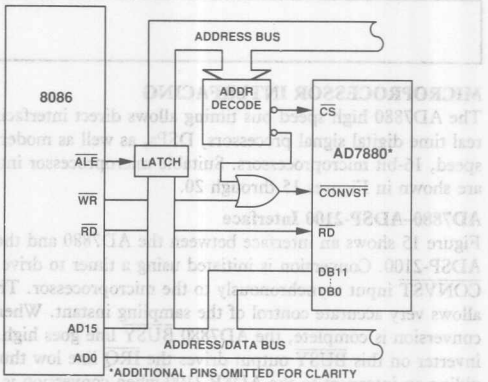

Figure 19. AD7880–8086 Interface

AD7880-6809 Interface

The AD7880 can also interface quite easily with 8-bit microprocessors. The 12-bit parallel data output from the AD7880 can be read into the microprocessor as an 8+4 byte structure. Figure 20 shows an interface to the MC6809 8-bit microprocessor. As in previous cases, conversion is initiated using an external timer. At the end of conversion, $\overline{BUSY}$ triggers a one-shot which drives the $\overline{IRQ}$ interrupt input of the microprocessor. A double read is then performed to two unique addresses. The first read fetches the lower 8 bits (DB0 – DB7) and loads the 74HC374 latch with the upper 4 bits (DB8 – DB11). The second read fetches these upper 4 bits.

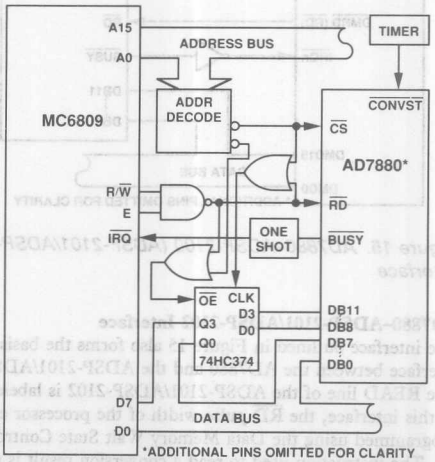

Figure 20. AD7880–6809 Interface

Good printed circuit board (PCB) layout is as important as the circuit design itself in achieving high speed A/D performance. The AD7880's comparator is required to make bit decisions on an LSB size of 1.22 mV. To achieve this, the designer must be conscious of noise both in the ADC itself and in the preceding analog circuitry. Switching mode power supplies are not recommended, as the switching spikes will feed through to the comparator causing noisy code transitions. Other causes of concern are ground loops and digital feedthrough from microprocessors. These are factors which influence any ADC, and a proper PCB layout which minimizes these effects is essential for best performance.

LAYOUT HINTS

Ensure that the layout for the printed circuit board has the digital and analog signal lines separated as much as possible. Take care not to run digital tracks alongside analog signal tracks. Guard (screen) the analog input with AGND.

Establish a single point analog ground (star ground) separate from the logic system ground at the AD7880 AGND pin or as the AD7880 DGND to this single analog ground point. Do not connect any other digital grounds to this analog ground point.

Low impedance analog and digital power supply common returns are essential to low noise operation of the ADC, so make the foil width for these tracks as wide as possible. The use of ground planes minimizes impedance paths and also guards the analog circuitry from digital noise. The circuit layout of Figures 26 and 27 have both analog and digital ground planes which are kept separated and only joined together at the AD7880 AGND pin.

NOISE

Keep the input signal leads to V_{IN} and signal return leads from AGND as short as possible to minimize input noise coupling. In applications where this is not possible, use a shielded cable between the source and the ADC. Reduce the ground circuit impedance as much as possible since any potential difference in grounds between the signal source and the ADC appears as an error voltage in series with the input signal.

ANALOG INPUT BUFFERING

To achieve specified performance, it is recommended that the analog input (V_{INA}, V_{INB}) be driven from a low impedance source. This necessitates the use of an input buffer amplifier. The choice of op amp will be a function of the particular application and the desired analog input range. The data acquisition circuit, described in this data sheet allows for various op amp configurations. Figure 21 shows the analog input buffer circuit.

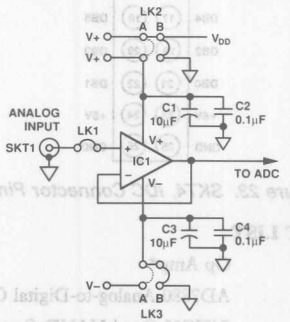

Figure 21. Analog Input Buffering

The options available to drive the supply of the op amp are:

Single +5 V (derived from PCB 5 V supply)

Dual Supply (externally supplied to V+ and V−)
±5 V, ±12 V or ±15 V

The simplest configuration is the 0 to 5 V range of Figure 5. A single supply 5 V op amp is recommended for such an implementation. This will allow for operation of the AD7880 in the 0 to 5 V unipolar range without supplying an external supply to V+ and V−. The 5 V supply is derived from the systems +5 V V_{DD} supply.

When it is required to drive the AD7880 with the 0 to 10 V input range, an external supply must be connected to V+ (see Figure 21).

In bipolar operation, positive and negative supplies must be connected to V+ and V−.

The AD711 is a general purpose op amp which could be used to drive the analog input of the AD7880.

POWER-DOWN CONTROL (MODE INPUT)

The AD7880 is designed for systems which need to have minimum power consumption. This includes such applications as hand held, portable battery powered systems and remote monitoring systems. As well as consuming minimum power under normal operating conditions, typically 20 mW, the AD7880 can be put into a power-down or sleep mode when not required to convert signals. When in this power-down mode, the AD7880 consumes approximately 2 mW of power.

The AD7880 is powered down by bringing the MODE input pin to a Logic Low in conjunction with keeping the $\overline{RD}$ input control High. The AD7880 will remain in the power-down mode until MODE is brought to a Logic High again. The MODE input should be driven with CD4000 or HCMOS logic levels.

It is recommended that one "dummy" conversion be implemented before reading conversion data from the AD7880 after it has been in the power-down mode. This is required to reset all internal logic and control circuitry. In a remote monitoring system where, say, 10 conversions are required to be taken with a sampling interval of 1 second, an additional 11th conversion must be carried out. Figure 22 gives a plot of power consump-

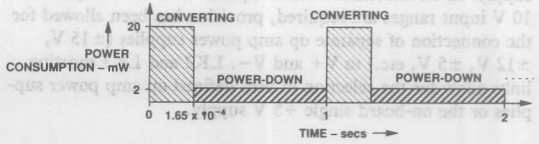

Figure 22. Power Consumption for Normal Operation and Power-Down Operation vs. Time

tion as a function of time for such operation. The total conversion time for each cycle is 11 × 15 μs (where 15 μs is the time taken for a single conversion) corresponding to 1.65×10^{-4} secs. Hence:

$$\text{Average Power} = \text{Power}_{\text{CONVERTING}} + \text{Power}_{\text{POWER-DOWN}}$$
$$= \{20\text{ mW} \times (1.65 \times 10^{-4})/(10)\} + \{2\text{ mW} \times (9.9998)/(10)\}$$
$$= 2.029\text{ mW}$$

AD7880 DATA ACQUISITION LAYOUT

Figure 24 shows the AD7880 in a data acquisition circuit. The corresponding printed circuit board (PCB) layout and silkscreen are shown in Figures 25 to 27.

The only additional component required for a full data acquisition system is an antialiasing filter. There is a component grid provided near the analog input on the PCB which may be used for such a filter or any other input conditioning circuitry. To facilitate this option there is a shorting link (labeled LK1 on the PCB) on the analog input track. With LK1 in place, the analog input connects to the buffer amplifier driving the AD7880. With LK1 removed, a wire link is needed to connect the analog input to the PCB component grid.

INTERFACE CONNECTIONS

The data acquisition board contains a parallel connection port labeled SKT4. This is a 26-contact IDC Connector and provides for direct microprocessor connection to the board. This connector, the pinout of which is shown in Figure 23, contains all data, control and status signals of the AD7880 (with the exception of the $\overline{\text{CONVST}}$ and the CLKIN inputs both of which are provided via SKT2 and SKT3 respectively). It also contains decoded R/$\overline{\text{W}}$ and $\overline{\text{STRB}}$ inputs which are necessary for interfacing to many microprocessors including the TMS320C25 and the Motorola 68000 series. Link LK7 selects $\overline{\text{RD}}$ directly or alternatively, the decoded version. Note that the AD7880 $\overline{\text{CS}}$ input must be decoded prior to the AD7880 evaluation board.

SKT1, SKT2 and SKT3 are three sub-miniature connectors (SMC) which provide input connections for the analog input, the $\overline{\text{CONVST}}$ input and the CLKIN input. Three different input ranges can be accepted by the AD7880 each of which is configured by selecting shorting plug options A, B or C of LK4. Position A corresponds to the 0 to 5 V unipolar configuration of Figure 5, position B corresponds to the bipolar ±5 V configuration of Figure 7 and position C allows for a 0 to +10 V unipolar range as shown in Figure 6.

POWER SUPPLY CONNECTIONS

The PCB requires a single +5 V power supply (labeled V_{DD}). Good decoupling allows this supply to drive the AD7880 V_{DD} which also drives the V_{REF} input as well as the op amp power supply. In circumstances where bipolar ±5 V or a unipolar 0 to 10 V input ranges are required, provision has been allowed for the connection of separate op amp power supplies (±15 V, ±12 V, ±5 V, etc.) to V+ and V−. LK2 and LK3 shorting links allow for the selection of user defined op amp power supplies or the on-board single +5 V supply.

LINK OPTIONS

There are seven link options which must be set before using the board. These are outlined below:

LK1	Connects the analog input to a buffer amplifier. The analog input may also be connected to a component grid for signal conditioning.
LK2, LK3	Allows for various op amp power supplies to be used to drive the input buffer of the AD7880. External supplies may be connected to V+ and V−. Alternatively, the AD7880's +5 V system supply and AGND can be selected to drive a single supply op amp.
LK4	Configures the various analog input ranges, 0 to 5 V, 0 to 10 V or ±5 V.
LK5	Selects reference input to V_{REF} of AD7880. Normally connected to V_{DD}. An external reference could also be wired in.
LK6	Selects power-down or sleep mode. The shorting plug is connected to V_{DD} for normal operation.
LK7	Connects the AD7880 $\overline{\text{RD}}$ input directly to the $\overline{\text{RD}}$ input of SKT4 or to a decoded $\overline{\text{STRB}}$ and R/$\overline{\text{W}}$ input. This shorting plug setting depends on the microprocessor, e.g., the TMS320C25 requires a decoded $\overline{\text{RD}}$ signal.

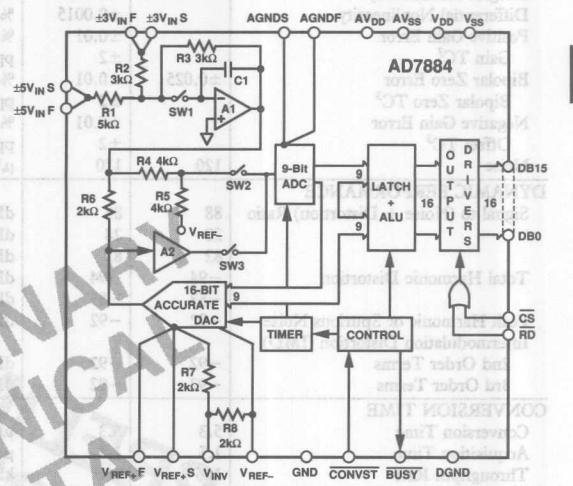
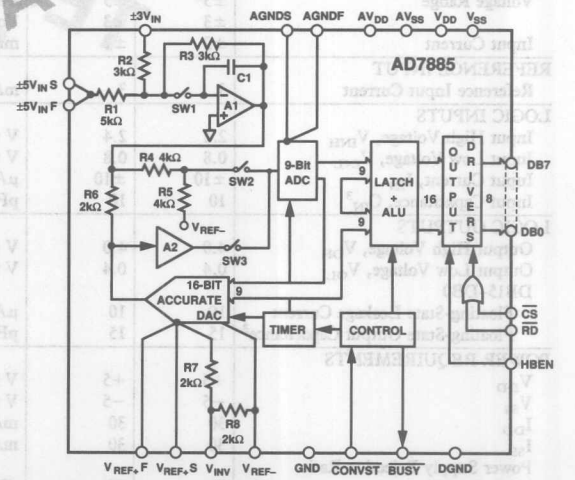
Robotics

GENERAL DESCRIPTION



The AD7884/AD7885 is a 16-bit monolithic analog-to-digital converter with internal sample-and-hold and a conversion time of 5.3 µsec. The maximum throughput rate is 166 kSPS. It uses a two pass flash architecture to achieve this speed. Two input ranges are available: ±5 V and ±3 V. Conversion is initiated by the $\overline{\text{CONVST}}$ signal. The result can be read into a microprocessor using the $\overline{\text{CS}}$ and $\overline{\text{RD}}$ inputs on the device. The AD7884 has a 16-bit parallel reading structure while the AD7885 has a byte reading structure. The conversion result is in 2s complement code.



The AD7884/AD7885 has its own internal oscillator which controls conversion. It runs from ±5 V supplies and needs a V_{REF+} of +3 V.

The AD7884 is available in 40-pin plastic and cerdip packages and in a 44-pin PLCC package.

The AD7885 is available in 28-pin plastic and cerdip packages and in a 28-pin PLCC package.

t_{11}	60	60	75	ns min	HBEN Low Pulse Duration
t_{12}	60	60	75	ns min	HBEN High Pulse Duration
t_{13}	40	40	40	ns max	Propagation Delay from HBEN Falling to Data Valid
t_{14}	40	40	40	ns max	Propagation Delay from HBEN Rising to Data Valid

NOTES

[1]Timing specifications in **bold** print are 100% production tested. All other times are sample tested at +5°C to ensure compliance. All input signals are specified with tr = tf = 5 ns (10% to 90% of 5 V) and timed from a voltage level of 1.6 V.

[2]t_6 is measured with the load circuit of Figure 1 and defined as the time required for an output to cross 0.8 V or 2.4 V.

[3]t_7 is derived from the measured time taken by the data outputs to change 0.5 V when loaded with the circuit of Figure 1. The measured number is then extrapolated back to remove the effects of charging or discharging the 100 pF capacitor. This means that the time, t_7, quoted in the Timing Characteristics is the true bus relinquish time of the part and as such is independent of external bus loading capacitances.

Specifications subject to change without notice.

ORDERING GUIDE

Model	Temperature Range	Linearity Error (% FSR)	SNR (dB)	Package Option*
AD7884AN	−40°C to +85°C		88	N-40

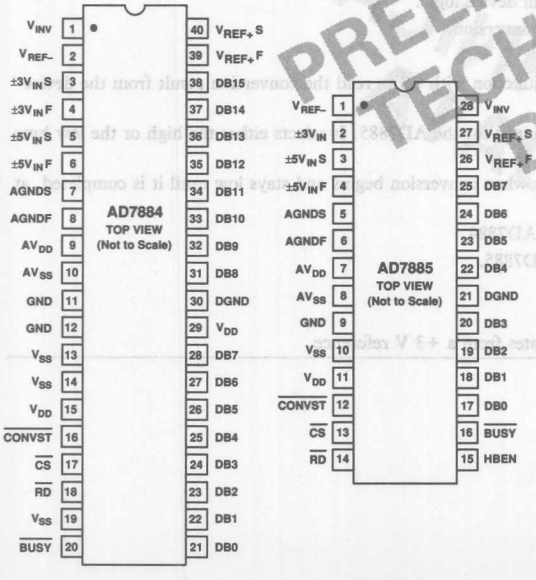
Derates above +75°C by . . . . . 10 mW/°C

*Stresses above those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. This is a stress rating only and functional operation of the device at these or any other conditions above those listed in the operational sections of this specification is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

2

CAUTION



ESD (electrostatic discharge) sensitive device. The digital control inputs are diode protected; however, permanent damage may occur on unconnected devices subject to high energy electrostatic fields. Unused devices must be stored in conductive foam or shunts. The protective foam should be discharged to the destination socket before devices are removed.

PIN CONFIGURATIONS

DIP

PLCC

This information applies to a product under development. Its characteristics and specifications are subject to change without notice. Analog Devices assumes no obligation regarding future manufacture unless otherwise agreed to in writing.

PIN FUNCTION DESCRIPTION

AD7884 Pin	AD7885 Pin	Description
V_{INV}	V_{INV}	This pin is connected to the inverting terminal of an op amp, as in Figure 6 and allows the inversion of the supplied +3 V reference.
V_{REF-}	V_{REF-}	This is the negative reference input and it can be obtained by using an external amplifier to invert the positive reference input. In this case, the amplifier output is connected to V_{REF-}. See Figure 6.
$\pm 3V_{IN}S$	—	This is the analog input sense pin for the ±3 volt analog input range on the AD7884.
$\pm 3V_{IN}F$	—	This is the analog input force pin for the ±3 volt analog input range on the AD7884. When using this input range, the ± 5 $V_{IN}F$ and ± 5 $V_{IN}S$ pins should be tied to AGND.
—	$\pm 3V_{IN}$	This is the analog input pin for the ±3 volt analog input range on the AD7885. When using this input range, the ± 5 $V_{IN}F$ and ± 5 $V_{IN}S$ pins should be tied to AGND.
$\pm 5V_{IN}S$	$\pm 5V_{IN}S$	This is the analog input sense pin for the ±5 volt analog input range on both the AD7884 and the AD7885.
$\pm 5V_{IN}F$	$\pm 5V_{IN}F$	This is the analog input force pin for the ±5 volt analog input range on both the AD7884 and AD7885. When using this input range, the ± 3 $V_{IN}F$ and ± 3 $V_{IN}S$ pins should be tied to AGND.
AGNDS	AGNDS	This is the ground return sense pin for the 9-bit ADC and the on-chip residue amplifier.
AGNDF	AGNDF	This is the ground return force pin for the 9-bit ADC and the on-chip residue amplifier.
AV_{DD}	AV_{DD}	Positive analog power rail for the sample-and-hold amplifier and the residue amplifier.
AV_{SS}	AV_{SS}	Negative analog power rail for the sample-and-hold amplifier and the residue amplifier.
GND	GND	This is the ground return for sample-and-hold section.
V_{SS}	V_{SS}	Negative supply for the 9-bit ADC.
V_{DD}	V_{DD}	Positive supply for the 9-bit ADC and all device logic.
$\overline{CONVST}$	$\overline{CONVST}$	This asynchronous control input starts conversion.
$\overline{CS}$	$\overline{CS}$	Chip Select control input.
$\overline{RD}$	$\overline{RD}$	Read control input. This is used in conjunction with $\overline{CS}$ to read the conversion result from the device output latch.
—	HBEN	High Byte Enable. Active high control input for the AD7885. It selects either the high or the low byte of the conversion for reading.
$\overline{BUSY}$	$\overline{BUSY}$	Busy output. The Busy output goes low when conversion begins and stays low until it is completed, at which time it goes high.
DB0–DB15	—	16-bit parallel data word output on the AD7884.
—	DB0–DB7	8-bit parallel data byte output on the AD7885.
DGND	DGND	Ground return for all device logic.
$V_{REF+}F$	$V_{REF+}F$	Reference force input.
$V_{REF+}S$	$V_{REF+}S$	Reference sense input. The device operates from a +3 V reference.

PRELIMINARY TECHNICAL DATA

This information applies to a product under development. Its characteristics and specifications are subject to change without notice. Analog Devices assumes no obligation regarding future manufacture unless otherwise agreed to in writing.

TERMINOLOGY

Integral Nonlinearity
This is the maximum deviation from a straight line passing through the endpoints of the ADC transfer function.

Differential Nonlinearity
This is the difference between the measured and the ideal 1 LSB change between any two adjacent codes in the ADC.

Bipolar Zero Error
This is the deviation of the midscale transition (all 0s to all 1s) from the ideal (AGND).

Positive Gain Error
This is the deviation of the last code transition (01 . . . 110 to 01 . . . 111) from the ideal ($+V_{REF+}$ S − 1 LSB).

Negative Gain Error
This is the deviation of the first code transition (10 . . . 000 to 10 . . . 001) from the ideal ($-V_{REF+}$S + 1 LSB)

Signal to (Noise + Distortion) Ratio
This is the measured ratio of signal to (noise + distortion) at the output of the A/D converter. The signal is the rms amplitude of the fundamental. Noise is the rms sum of all nonfundamental signals up to half the sampling frequency ($f_S/2$), excluding dc. The ratio is dependent upon the number of quantization levels in the digitization process; the more levels, the smaller the quantization noise. The theoretical signal to (noise + distortion) ratio for an ideal N-bit converter with a sine wave input is given by:

$$Signal\ to\ (Noise + Distortion) = (6.02N + 1.76)\ dB$$

Thus for a 16-bit converter, this is 98 dB.

Total Harmonic Distortion
Total harmonic distortion (THD) is the ratio of the rms sum of harmonics to the fundamental. For the AD7884/AD7885, it is defined as:

$$THD\ (dB) = 20\ log\ \frac{\sqrt{V_2^2 + V_3^2 + V_4^2 + V_5^2 + V_6^2}}{V_1}$$

where V_1 is the rms amplitude of the fundamental and V_2, V_3, V_4, V_5 and V_6 are the rms amplitudes of the second through the sixth harmonics.

Peak Harmonic or Spurious Noise
Peak harmonic or spurious noise is defined as the ratio of the rms value of the next largest component in the ADC output spectrum (up to $f_S/2$ and excluding dc) to the rms value of the fundamental. Normally, the value of this specification is determined by the largest harmonic in the spectrum, but for parts where the harmonics are buried in the noise floor, it will be a noise peak.

Intermodulation Distortion
With inputs consisting of sine waves at two frequencies, fa and fb, any active device with nonlinearities will create distortion products at sum and difference frequencies of mfa ± nfb where m, n = 0, 1, 2, 3, etc. Intermodulation terms are those for which neither m or n are equal to zero. For example, the second order terms include (fa + fb) and (fa − fb), while the third order terms include (2fa + fb), (2fa − fb), (fa + 2fb) and (fa − 2fb).

The AD7884/AD7885 is tested using the CCIFF standard where two input frequencies near the top end of the input bandwidth are used. In this case, the second and third order terms are of different significance. The second order terms are usually distanced in frequency from the original sine waves while the third order terms are usually at a frequency close to the input frequencies. As a result, the second and third order terms are specified separately. The calculation of the intermodulation distortion is as per the THD specification where it is the ratio of the rms sum of the individual distortion products to the rms amplitude of the fundamental expressed in dBs.

Power Supply Rejection Ratio
This is the ratio, in dBs, of the change in positive gain error to the change in V_{DD} or V_{SS}. It is a dc measurement.

OPERATIONAL DIAGRAM

An operational diagram for the AD7884/AD7885 is shown in Figure 6. It is set up for an analog input range of ±5 V. If a ±3 V input range is required, A1 should drive ±3 V_{IN}S and ±3 V_{IN}F with ±5 V_{IN}S, ±5 V_{IN}F being tied to system AGND.

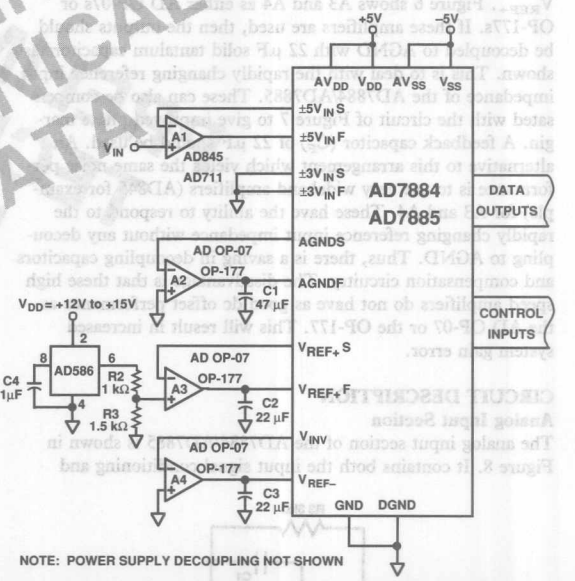

Figure 6. AD7884/AD7885 Operational Diagram

The chosen input buffer amplifier (A1) should have low noise and distortion and fast settling time for high bandwidth applications. Both the AD711 and the AD845 are suitable amplifiers.

A2 is the force, sense amplifier for AGND. The AGNDS pin should be at zero potential. Therefore, the amplifier must have a very low input offset voltage and good noise performance. For these reasons, either the AD OP-07 or OP-177 is recommended. The output of A2 is decoupled with a 47 µF solid tantalum capacitor to AGND to deal with the fast current transients on the

PRELIMINARY TECHNICAL DATA

This information applies to a product under development. Its characteristics and specifications are subject to change without notice. Analog Devices assumes no obligation regarding future manufacture unless otherwise agreed to in writing.

If the user wishes to improve the phase margin, the circuit given in Figure 7 may be used. A feedback capacitor (R_F) of 47 μF should be used. This circuit compensates for the load capacitor by adding a low frequency zero and ensures an adequate phase margin.

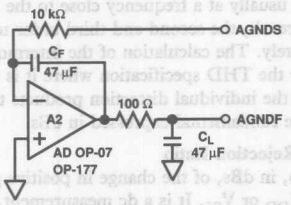

Figure 7. Compensation Circuit for A2

The required +3 V reference is derived from the AD586. The +5 V output is divided down to +3 V by R2 and R3 before being buffered by A3. A4 is a unity gain inverter which provides the −3 V negative reference. The gain setting resistors are on-chip and are factory trimmed to ensure precise tracking of V_{REF+}. Figure 6 shows A3 and A4 as either AD OP-07s or OP-177s. If these amplifiers are used, then the outputs should be decoupled to AGND with 22 μF solid tantalum capacitors as shown. This is to deal with the rapidly changing reference input impedance of the AD7884/AD7885. These can also be compensated with the circuit of Figure 7 to give improved phase margin. A feedback capacitor (C_F) of 22 μF should be used. An alternative to this arrangement which yields the same noise performance is to use very wideband amplifiers (AD845 for example) for A3 and A4. These have the ability to respond to the rapidly changing reference input impedance without any decoupling to AGND. Thus, there is a saving in decoupling capacitors and compensation circuitry. The disadvantage is that these high speed amplifiers do not have as good dc offset performance as the AD OP-07 or the OP-177. This will result in increased system gain error.

CIRCUIT DESCRIPTION

Analog Input Section

The analog input section of the AD7884/AD7885 is shown in Figure 8. It contains both the input signal conditioning and

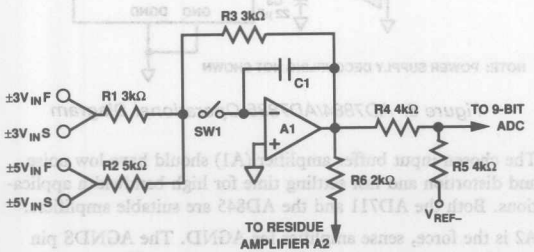

Figure 8. AD7884/AD7885 Analog Input Section

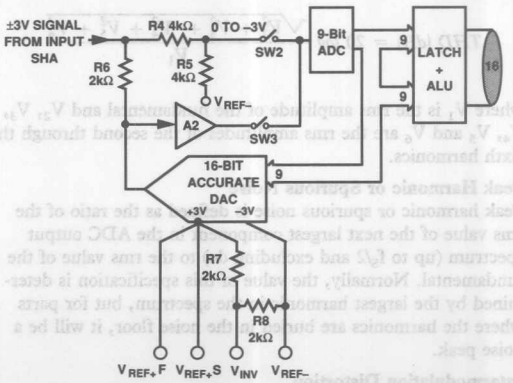
inputs are tied to 0 V, the input section has a gain of −0.6 and transforms an input signal of ±5 volts to the required ±3 volts. When the ±5 $V_{IN}S$ and ±5 $V_{IN}F$ inputs are grounded, the input section has a gain of −1 and so the analog input range is now ±3 volts. Resistors R4 and R5, at the amplifier output, further condition the ±3 volts signal to be 0 to −3 volts. This is the required input for the 9-bit A/D converter section.

With SW1 closed, the output of A1 follows the input (the sample-and-hold is in the track mode). On the rising edge of the $\overline{\text{CONVST}}$ pulse, SW1 goes open circuit, and capacitor C1 holds the voltage on the output of A1. The sample-and-hold is now in the hold mode. The aperture delay time for the sample-and-hold is nominally 50 ns.

A/D Converter Section

The AD7884/AD7885 uses a two-pass flash technique in order to achieve the required speed and resolution. When the $\overline{\text{CONVST}}$ control input goes from low to high, the sample-and-hold amplifier goes into the hold mode and a 0 V to −3 V signal is presented to the input of the 9-bit ADC. The first phase of conversion generates the 9 MSBs of the 16-bit result and transfers these to the latch and ALU combination. They are also fed back to the 9 MSBs of the 16-bit DAC. The 7 LSBs of the DAC are permanently loaded with 0s. The DAC output is subtracted from the analog input with the result being amplified and offset in the Residue Amplifier Section. The signal at the output of A2 is proportional to the error between the first phase result and the actual analog input signal and is digitized in the second conversion phase. This second phase begins when the 16-bit DAC and the Residue Error Amplifier have both settled. First, SW2 is turned off and SW3 is turned on. The 9-bit result is transferred to the output latch and ALU. An error correction algorithm now compensates for the offset inserted in the Residue Amplifier Section and errors introduced in the first pass conversion and combines both results to give the 16-bit answer.



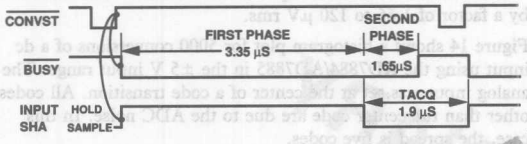


Figure 9. A/D Converter Section

This information applies to a product under development. Its characteristics and specifications are subject to change without notice. Analog Devices assumes no obligation regarding future manufacture unless otherwise agreed to in writing.

Timing and Control Section

Figure 10 shows the timing and control sequence for the AD7884/AD7885. When the part receives a $\overline{\text{CONVST}}$ pulse, the conversion begins. The input sample-and-hold goes into the hold mode 50 ns after the rising edge of $\overline{\text{CONVST}}$ and $\overline{\text{BUSY}}$ goes low. This is the first phase of conversion and takes 3.35 μs to complete. The second phase of conversion begins when SW2 is turned off and SW3 turned on. The Residue Amplifier and SHA section (A2 in Figure 9) goes into hold mode at this point and allows the input sample-and-hold to go back into sample mode. Thus, while the second phase of conversion is ongoing, the input sample-and-hold is also acquiring the input signal for the next conversion. This overlap between conversion and acquisition allows throughput rates of 166 kSPS to be achieved.

PRELIMINARY TECHNICAL DATA

USING THE AD7884/AD7885

Analog Input Ranges

The AD7884/AD7885 can be set up to have either a ±3 volts analog input range or a ±5 volts analog input range. Figures 11 and 12 show the necessary corrections for each of these. The output code is 2s complement and the ideal code table for both input ranges is shown in Table I.

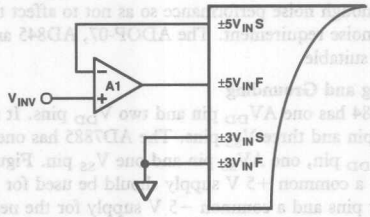

Figure 11. ±5 V Input Range Connections

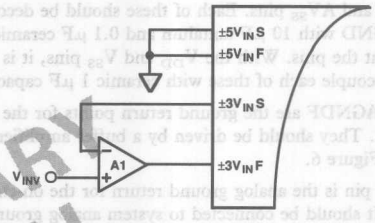

Figure 12. ±3 V Input Range Connections

Reference Considerations

The AD7884/AD7885 operates from a ±3 volt reference. This can be derived simply from any single +5 volt reference as shown in Figure 6.

The critical performance specification for a reference in a 16-bit application is noise. The reference pk-pk noise should be insignificant in comparison to the ADC noise. The AD7884/AD7885 has a typical rms noise of 120 μV. For example a reasonable target would be to keep the total rms noise less than 125 μV. To do this the reference noise needs to be less than 35 μV rms. Using a crest factor of 3.3 this corresponds to a pk-pk noise of 230 μV. Both the AD586 and the AD REF-02 noise is lower than this, making both suitable.

Table I. Ideal Output Code Table for the AD7884/AD7885

Analog Input			Digital Output
In Terms of FSR[2]	±3 V Range[3]	±5 V Range[4]	Code Transition[1]
+FSR/2 − 1 LSB	2.999908	4.999847	011 . . . 111 to 011 . . . 110
+FSR/2 − 2 LSBs	2.999817	4.999695	011 . . . 110 to 011 . . . 101
+FSR/2 − 3 LSBs	2.999726	4.999543	011 . . . 101 to 011 . . . 100
AGND + 1 LSB	0.000092	0.000153	000 . . . 001 to 000 . . . 000
AGND	0.000000	0.000000	000 . . . 000 to 111 . . . 111
AGND − 1 LSB	−0.000092	−0.000153	111 . . . 111 to 111 . . . 110
−(FSR/2 − 3 LSBs)	−2.999726	−4.999543	100 . . . 011 to 100 . . . 010
−(FSR/2 − 2 LSBs)	−2.999817	−4.999695	100 . . . 010 to 100 . . . 001
−(FSR/2 − 1 LSB)	−2.999908	−4.999847	100 . . . 001 to 100 . . . 000

NOTES
[1]This table applies for $V_{REF+}S$ = +3 V.
[2]FSR (Full-Scale Range) is 6 volts for the ±3 V input range and 10 volts for the ±5 V input range.
[3]1 LSB on the ±3 V range is FSR/2^{16} and is equal to 91.5 μV.
[4]1 LSB on the ±5 V range is FSR/2^{16} and is equal to 152.6 μV.

This information applies to a product under development. Its characteristics and specifications are subject to change without notice. Analog Devices assumes no obligation regarding future manufacture unless otherwise agreed to in writing.

The buffer amplifier used to drive the device V_{REF+} should have low enough noise performance so as not to affect the overall system noise requirement. The ADOP-07, AD845 and OP-177 are all suitable.

Decoupling and Grounding

The AD7884 has one AV_{DD} pin and two V_{DD} pins. It also has one AV_{SS} pin and three V_{SS} pins. The AD7885 has one AV_{DD} pin, one V_{DD} pin, one AV_{SS} pin and one V_{SS} pin. Figure 6 shows how a common +5 V supply should be used for the positive supply pins and a common −5 V supply for the negative supply pins.

For decoupling purposes, the critical pins on both devices are the AV_{DD} and AV_{SS} pins. Each of these should be decoupled to system AGND with 10 μF tantalum and 0.1 μF ceramic capacitors right at the pins. With the V_{DD} and V_{SS} pins, it is sufficient to decouple each of these with ceramic 1 μF capacitors.

AGNDS, AGNDF are the ground return points for the on-chip 9-bit ADC. They should be driven by a buffer amplifier as shown in Figure 6.

The GND pin is the analog ground return for the on-chip linear circuitry. It should be connected to system analog ground.

The DGND pin is the ground return for the on-chip digital circuitry. It should be connected to the ground terminal of the V_{DD} and V_{SS} supplies. If a common analog supply is used for AV_{DD} and V_{DD} then DGND should be connected to the common ground point.

Power Supply Sequencing

If the AD7884/AD7885 is being powered from separate analog and digital supplies, then care should be taken with power supply sequencing. AV_{DD} should always come up before V_{DD} and AV_{SS} should always come up before V_{SS}. If this cannot be guaranteed, Schottky diodes (HP5082-2810 or equivalent) should be used to ensure that V_{DD} never exceeds AV_{DD} by more than 0.3 V and that V_{SS} never goes below AV_{SS} by more than 0.3 V.

AD7884/AD7885 PERFORMANCE

Linearity

The linearity of the AD7884/AD7885 is determined by the on-chip 16-bit D/A converter. This is a segmented DAC which is laser trimmed for 16-bit DNL performance to ensure that there are no missing codes in the ADC transfer function. Figure 13 shows a typical INL plot for the AD7884/AD7885.

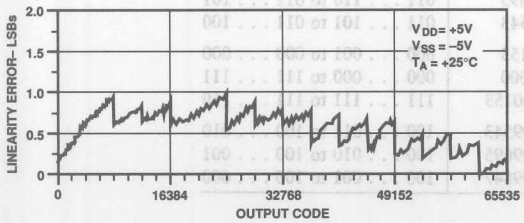

Figure 13. AD7884/AD7885 Typical Linearity Performance

Noise

In an A/D converter, noise exhibits itself as code uncertainty in dc applications and as the noise floor (in an FFT, for example) in ac applications.

In a sampling A/D converter like the AD7884/AD7885, all information about the analog input appears in the baseband from dc to 1/2 the sampling frequency. An antialiasing filter will remove unwanted signals above fs/2 in the input signal but the converter wideband noise will alias into the baseband. In the AD7884/AD7885, this noise is made up of sample-and-hold noise and a/d converter noise. The sample-and-hold section contributes 51 μV rms and the ADC section contributes 59 μV rms. These add up to a total rms noise of 78 μV. This is the input referred noise in the ±3 V analog input range. When operating in the ±5 V input range, the input gain is reduced to −0.6. This means that the input referred noise is now increased by a factor of 1.66 to 120 μV rms.

Figure 14 shows a histogram plot for 5000 conversions of a dc input using the AD7884/AD7885 in the ±5 V input range. The analog input was set at the center of a code transition. All codes other than the center code are due to the ADC noise. In this case, the spread is five codes.

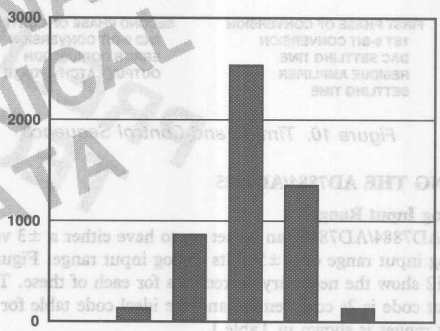

Figure 14. Histogram of 5000 Conversions of a DC Input

If the noise in the converter is too high for an application, it can be reduced by oversampling and digital filtering. This involves sampling the input at higher than the required word rate and then averaging to arrive at the final result. The very fast conversion time of the AD7884/AD7885 makes it very suitable for oversampling. For example, if the required input bandwidth is 50 kHz, the AD7884/AD7885 could be oversampled by a factor of 2. This yields a 3 dB improvement in the effective SNR performance. The noise performance in the ±5 volt input range is now effectively 85 μV rms and the resultant spread of codes for 2500 conversions will be four. This is shown in Figure 15.

PRELIMINARY TECHNICAL DATA

This information applies to a product under development. Its characteristics and specifications are subject to change without notice. Analog Devices assumes no obligation regarding future manufacture unless otherwise agreed to in writing.

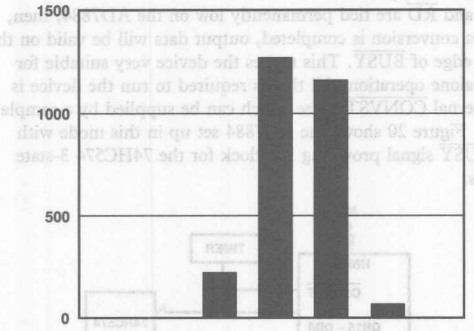

Figure 15. Histogram of 2500 Conversions of a DC Input Using a ×2 Oversampling Ratio

Dynamic Performance

With a combined conversion and acquisition time of 6 µs, the AD7884/AD7885 is ideal for wide bandwidth signal processing applications. Signal to (Noise + Distortion), Total Harmonic Distortion, Peak Harmonic or Spurious Noise and Intermodulation Distortion are all specified. Figure 16 shows a typical FFT plot of a 1.8 kHz, ±5 V input after being digitized by the AD7884/AD7885.

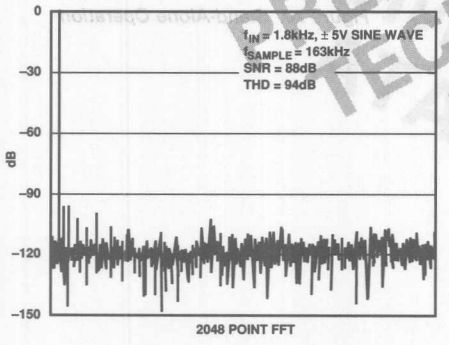

Figure 16. AD7884/AD7885 FFT Plot

MICROPROCESSOR INTERFACING

The AD7884/AD7885 is designed on a high speed process which results in very fast interfacing timing. The AD7884 has a full 16-bit parallel bus and the AD7885 has an 8-bit wide bus.

AD7884–MC68000 Interface

Figure 17 shows a general interface diagram for the MC68000, 16-bit microprocessor to the AD7884. In Figure 17, conversion is initiated by bringing $\overline{CSA}$ low (i.e., writing to the appropriate address). This allows the processor to maintain control over the complete conversion process. In some cases it may be more desirable to control conversion independent from the processor. This can be done by using an external sampling timer.

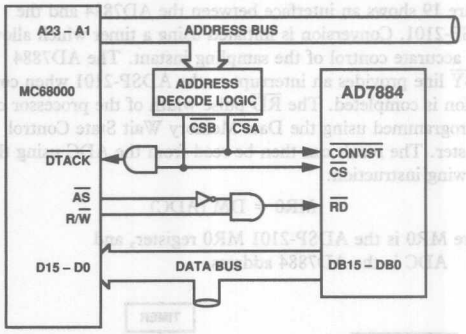

Figure 17. AD7884 to MC68000 Interface

Once conversion has been started, the processor must wait until it is completed before reading the result. There are two ways of ensuring this. The first way is to simply use a software delay to wait for 6.5 µs before bringing $\overline{CS}$ and $\overline{RD}$ low to read the data. The second way is to use the $\overline{BUSY}$ output of the AD7884 to generate an interrupt in the MC68000. Because of the nature of its interrupts, the MC68000 requires additional logic (not shown in Figure 17) to allow it to be interrupted correctly. For full information on this, consult the MC68000 User's Manual.

AD7885 to 8088 Interface

The AD7885, with its byte (8 + 8) data format, is ideal for use with the 8088 microprocessor. Figure 18 is the interface diagram. Conversion is started by enabling $\overline{CSA}$. At the end of conversion, data is read into the processor. The read instructions are:

```
MOV AX, C001    Read 8 MSBs of data
MOV AX, C000    Read 8 LSBs of data
```

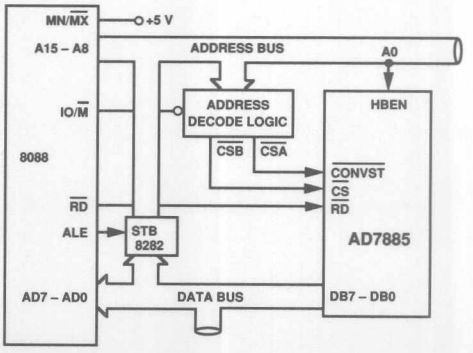

Figure 18. AD7885 to 8088 Interface

This information applies to a product under development. Its characteristics and specifications are subject to change without notice. Analog Devices assumes no obligation regarding future manufacture unless otherwise agreed to in writing.

AD7884 to ADSP-2101 Interface

Figure 19 shows an interface between the AD7884 and the ADSP-2101. Conversion is initiated using a timer which allows very accurate control of the sampling instant. The AD7884 $\overline{BUSY}$ line provides an interrupt to the ADSP-2101 when conversion is completed. The $\overline{RD}$ pulse width of the processor can be programmed using the Data Memory Wait State Control Register. The result can then be read from the ADC using the following instruction:

MR0 = DM (ADC)

where MR0 is the ADSP-2101 MR0 register, and
ADC is the AD7884 address.

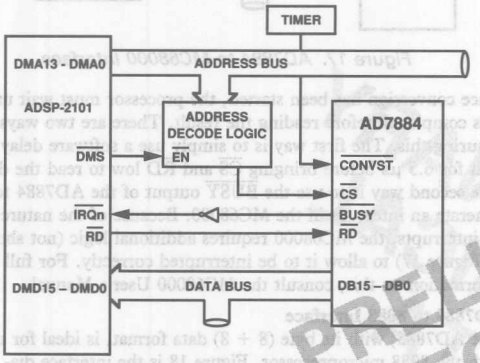

Figure 19. AD7884 to ADSP-2101 Interface

Stand-Alone Operation

If $\overline{CS}$ and $\overline{RD}$ are tied permanently low on the AD7884, then, when a conversion is completed, output data will be valid on the rising edge of $\overline{BUSY}$. This makes the device very suitable for stand-alone operation. All that is required to run the device is an external $\overline{CONVST}$ pulse which can be supplied by a sample timer. Figure 20 shows the AD7884 set up in this mode with the $\overline{BUSY}$ signal providing the clock for the 74HC574 3-state latches.

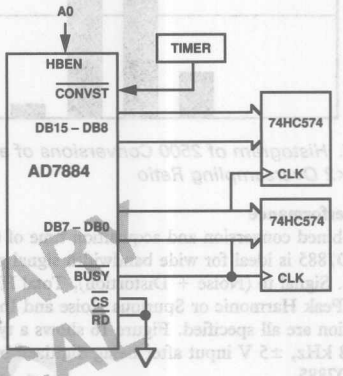

Figure 20. Stand-Alone Operation

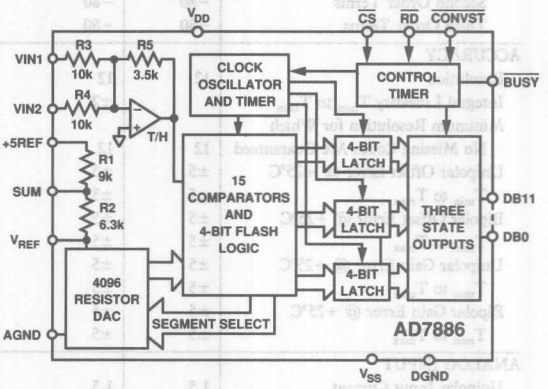
ANALOG DEVICES

LC²MOS 12-Bit, 750 kHz, Sampling ADC



AD7886

2

FEATURES
- 750 kHz Throughput Rate
- 1 μs Conversion Time
- 12-Bit No Missed Codes Over Temperature
- 67 dB SNR at 100 kHz Input Frequency
- Low Power—250 mW typ
- Fast Bus Access Time—57 ns max

APPLICATIONS
- Digital Signal Processing
- Speech Recognition and Synthesis
- Spectrum Analysis
- DSP Servo Control

FUNCTIONAL BLOCK DIAGRAM

GENERAL DESCRIPTION

The AD7886 is 12-bit ADC with a sample-and-hold amplifier offering high speed performance combined with low power dissipation. The AD7886 is a triple pass flash ADC, which uses 15 comparators in a 4-bit flash technique to achieve 12-bit accuracy in 1 μs conversion time. An on-chip clock oscillator provides the appropriate timing for each of the three conversion stages eliminating the need for any external clocks. Acquisition time of the sample-and-hold amplifier is less than 333 ns giving a resulting throughput rate of 750 kHz.

The AD7886 operates from ±5 V power supplies. Pin-strappable inputs offer a choice of three analog input ranges; 0 to 5 V, 0 to 10 V or ±5 V.

In addition to the traditional dc accuracy specifications such as linearity, offset and full-scale errors, the AD7886 is also specified for dynamic performance parameters including harmonic distortion and signal-to-noise ratio at a sampling frequency of 750 kHz.

The AD7886 has a high speed digital interface with three-state data outputs. Conversion control is provided by a $\overline{\text{CONVST}}$ input. Data access is controlled by $\overline{\text{CS}}$ and $\overline{\text{RD}}$ inputs, standard microprocessor signals. The data access time of less than 57 ns means that the AD7886 can interface directly to most modern microprocessors including DSP processors.

The AD7886 is fabricated in Analog Devices' Linear Compatible CMOS process, a mixed technology process that combines precision bipolar circuits with low power CMOS logic.

The AD7886 is available in both a 28-pin DIP and in a 28-pin leaded chip carrier.

PRODUCT HIGHLIGHTS

1. Fast 1.333 μs Throughput Time.
   Fast 1.333 μs throughput time makes the AD7886 suitable for a wide range of data acquisition applications.
2. Dynamic Specifications for DSP Users.
   The AD7886 is specified for ac parameters, including signal-to-noise ratio, harmonic distortion and intermodulation distortion. Key digital timing parameters are also tested and guaranteed over the full operating temperature range.
3. Fast Microprocessor Interface.
   Standard control signals, $\overline{\text{CS}}$ and $\overline{\text{RD}}$, and fast bus access times make the AD7886 easy to interface to microprocessors.
4. Low Power.
   LC²MOS fabrication process gives low power dissipation of 250 mW.

NOTES

[1]Timing specifications in **bold print** are 100% production tested. All other times are sample tested at +25°C to ensure compliance. All input signals are specified with tr = tf = 5 ns (10% to 90% of 5 V) and timed from a voltage level of 1.6 V.

[2]t_6 is measured with the load circuit of Figure 1 and defined as the time required for an output to cross 0.8 V or 2.4 V.

[3]t_7 and t_9 are derived from the measured time taken by the data outputs to change by 0.5 V when loaded with the circuit of Figure 1. The measured number is then extrapolated back to remove the effects of charging or discharging the load capacitor, C_L. This means that the times, t_7 and t_9, quoted in the timing characteristics are the true bus relinquish times of the part and as such are independent of external bus loading capacitances.

Specifications subject to change without notice.

Derates above +75°C by . . . . . 10 mW/°C

[1]Stresses above those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. This is a stress rating only and functional operation of the device at these or any other conditions above those listed in the operational sections of this specification is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

[2]If V_{SS} is open circuited with V_{DD} and AGND applied, the V_{SS} pin will be pulled positive, exceeding the Absolute Maximum Ratings. If this possibility exists, a Schottky diode from V_{SS} to DGND (cathode end to GND) ensures that the Absolute Maximum Ratings will be observed.

CAUTION

ESD (electrostatic discharge) sensitive device. The digital control inputs are diode protected; however, permanent damage may occur on unconnected devices subject to high energy electrostatic fields. Unused devices must be stored in conductive foam or shunts. The protective foam should be discharged to the destination socket before devices are inserted.

ORDERING GUIDE

Model[1, 2]	Temperature Range	SNR (dBs)	Integral Nonlinearity (LSBs)	Package Option[3]
AD7886JD	0°C to +70°C	65		D-28
AD7886KD	0°C to +70°C	67	±2.0	D-28
AD7886JP	0°C to +70°C	65		P-28A[2]
AD7886KP	0°C to +70°C	67	±2.0	P-28A[2]
AD7886BD	−40°C to +85°C	67	±2.0	D-28
AD7886TD	−55°C to +125°C	65	±2.0	D-28

PIN FUNCTION DESCRIPTION

DIP Pin Number	Mnemonic	Description
Power Supply		
10 & 19	V_{DD}	Positive Power Supply, +5 V ± 5%. Both V_{DD} pins must be tied together.
15 & 24	V_{SS}	Negative Power Supply, −5 V ± 5%. Both V_{SS} pins must be tied together.
16 & 23	AGND	Analog Ground. Both AGND pins must be tied together.
5	DGND	Digital Ground.
Analog and Reference Inputs		
17 & 18	VIN	Analog Inputs, VIN1 and VIN2. The part can be pin strapped for any one of three analog input ranges;

Range	Pin Strap	Signal Input
0 to 5 V	Connect VIN2 to VIN1	VIN1 & VIN2
0 to 10 V	Connect VIN2 to GND	VIN1
±5 V	Connect VIN2 to +5 V	VIN1

20	+5REF	+5 V Reference input. This input is used in conjunction with SUM and V_{REF} inputs to scale an external +5 V reference to −3.5 V, the required reference for the part, see Figure 2.
21	SUM	Summing Point. This input is used in conjunction with +5REF and V_{REF} inputs to scale an external +5 V reference to −3.5 V, the required reference for the part, see Figure 2.
22	V_{REF}	Voltage Reference Input. The AD7886 is specified with V_{REF} = −3.5 V.
Interface and Control		
1–4,	DB7–DB4	Three-state data outputs.
6–9,	DB3–DB0	These outputs are controlled by $\overline{CS}$ and $\overline{RD}$. DB11 is the Most Significant Bit (MSB).
25–28	DB11–DB8	
11	$\overline{BUSY}$	$\overline{BUSY}$ Output indicates converter status. $\overline{BUSY}$ is low during conversion.
12	$\overline{CS}$	Chip Select Input. The device is selected when this input is low.
13	$\overline{RD}$	Read Input. This active low signal, in conjunction with $\overline{CS}$, is used to enable the output data three-state drivers.
14	$\overline{CONVST}$	Conversion Start Input. This input is used to start conversion.

TERMINOLOGY

Unipolar Offset Error

The ideal first code transition should occur when the analog input is 1 LSB above AGND. The deviation of the actual transition from that point is termed the offset error.

Bipolar Zero Error

The ideal midscale transition (i.e., 0111 1111 1111 to 1000 0000 0000 for the ±5 V range should occur when the analog input is at zero volts. Bipolar zero error is the deviation of the actual transition from that point.

Gain Error

In the unipolar mode, gain error is measured with respect to the first and last code transition points. The ideal difference between these points if FS−2 LSBs. For bipolar applications, the gain error is measured from the midscale transition to both the first and last code transitions. The ideal difference in this case is FS/2−1 LSB. The gain error is defined as the deviation between the ideal difference, given above, and the measured difference. For the bipolar case, there are two gain errors, the figure in the specification page represents the worst case. Ideal FS depends on the +5REF input; for the 0 to 5 V input, ideal FS = +5REF and for the 0 to 10 V and ±5 V ranges, ideal FS = 2 × +5REF.

CONVERTER DETAILS

The AD7886 is a triple-pass flash ADC which uses 15 comparators in a 4-bit flash technique to perform the 12-bit conversion procedure. Each of the 4096 quantization levels is realized internally with a precision resistor DAC.

The fifteen comparators first compare the analog input voltage to the $V_{REF}/16$ voltages of the resistor array. This determines the four most significant bits and selects 1 out of 16 voltage segments. The comparators are then switched to 15 subvoltages on that segment to determine the next four bits and select 1 out of 256 voltage segments. A further switching of the comparators to another 15 subvoltages produces the complete 12-bit conversion result. The 12 bits of data are then stored internally in a three-state output latch.

REFERENCE INPUT

The AD7886 operates from a −3.5 V reference which must be provided at the V_{REF} input. Two on-chip resistors for use with an external amplifier can be used for deriving −3.5 V from standard 5 V references. Figure 2 shows an example with the AD586 which a is a high performance voltage reference which exhibits excellent stability performance, 5 ppm/°C max. The external amplifier serves a second function of force/sensing the V_{REF} input. Force/sensing minimizes error contributions from

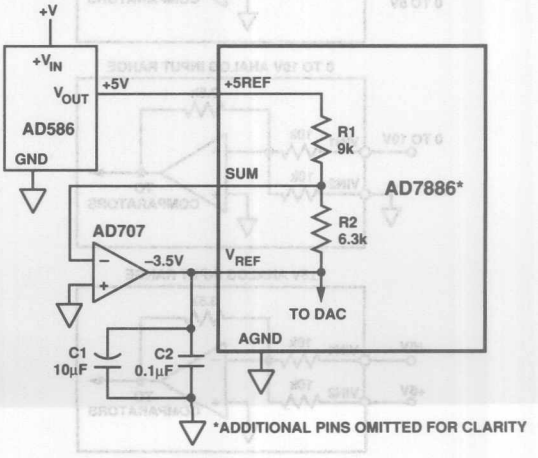

Figure 2. Typical Reference Circuitry

voltage or IR drops along the internal conductors. IR drops in the reference path cause a gain error, and typically the external amplifier reduces this error by 2 LSBs. In systems where a −3.5 V reference is available then it can be applied to the V_{REF} input directly causing a slight increase in gain error. A low op amp offset voltage is important as any offset voltage will add directly to the voltage that is being force/sensed. Suitable op amps for this application are precision op amps such as the AD705 or the AD707 which feature offset voltages of less than 100 μV.

Proper decoupling on the op amp output is important to suppress high speed transients during the conversion procedure. Note, connecting capacitors directly to op amp outputs can cause stability problems. However, the use of large capacitors, 10 μF in Figure 2, limits the open-loop bandwidth preventing any closed-loop oscillations.

TRACK-AND-HOLD AMPLIFIER

The analog input is sampled by an on-chip track-and-hold amplifier before being applied to the ADC. The 3dB bandwidth of this amplifier is typically 20 MHz which is much greater than the Nyquist limit of the ADC, so it can be used for undersampling applications. The track-and-hold amplifier acquires the input signal to 12-bit accuracy in less than 333 ns. The overall throughput time is equal to the conversion time plus the track/hold amplifier acquisition time which is 1.333 μs for the AD7886.

The operation of the track/hold amplifier is essentially transparent to the user. The track-to-hold transition occurs at the start of conversion on the falling edge of $\overline{\text{CONVST}}$. The conversion procedure does not start until the rising edge of $\overline{\text{CONVST}}$. The width of the $\overline{\text{CONVST}}$ pulse low time determines the track-to-hold settling time. The track/hold reverts back to the track mode at the end of conversion when $\overline{\text{BUSY}}$ has returned high.

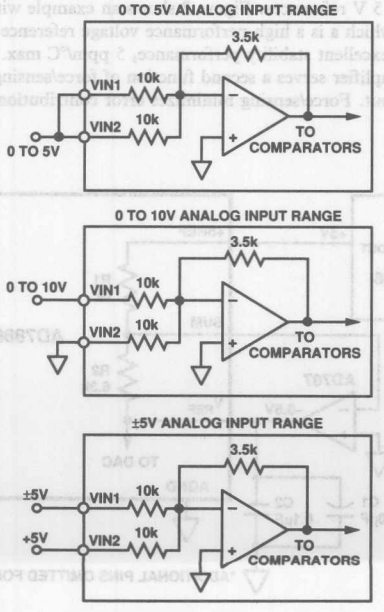

Figure 3. Analog Input Range Configurations

ANALOG INPUT RANGES

The AD7886 has three user selectable analog input ranges: 0 to 5 V, 0 to 10 V and ±5 V. Figure 3 shows how to configure the two analog inputs (VIN1 and VIN2) for these ranges.

UNIPOLAR OPERATION

Figure 4 shows a typical unipolar circuit for the AD7886. The ideal input/output characteristic is shown in Figure 5. The designed code transitions occur on integer multiples of 1 LSB.

The output code is natural binary with 1 LSB = FS/4096. FS is either +5 V or +10 V depending on how the analog inputs are configured.

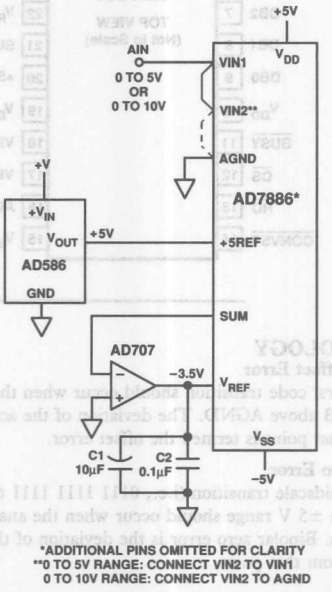

Figure 4. Unipolar Operation

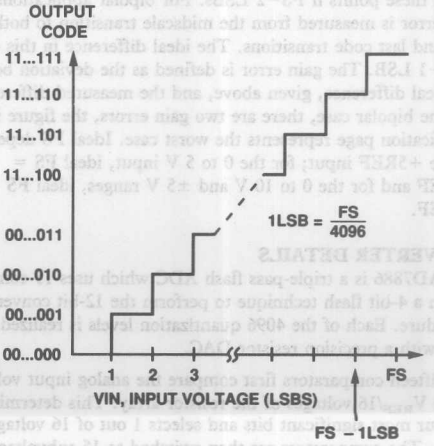

Figure 5. Ideal Input/Output Transfer Characteristic for Unipolar Operation

OFFSET AND GAIN ADJUSTMENT

In most digital signal processing (DSP) applications, offset and full-scale errors have little or no effect on system performance. Offset error can usually be eliminated in the analog domain by ac coupling. Full-scale errors do not cause problems as long as the input signal is within the full dynamic range of the ADC. For applications which require that the input signal range match the full analog input dynamic range of the ADC, offset and full-scale errors have to be adjusted to zero.

UNIPOLAR OFFSET AND GAIN ERROR ADJUSTMENT

If absolute accuracy is an application requirement, then offset and gain can be adjusted to zero. Offset error must be adjusted before gain error. Zero offset is achieved by adjusting the offset of the op amp driving the analog input (i.e., A1 in Figure 6). For zero offset error apply a voltage of 1 LSB to AIN and adjust the op amp offset until the ADC output code flickers between 0000 0000 0000 and 0000 0000 0001.

0 to 5 V Range: 1 LSB = 1.22 mV
0 to 10 V Range: 1 LSB = 2.44 mV

For zero gain error apply an analog input voltage equal to FS−1 LSB (last code transition) at AIN and adjust R3 until the ADC output code flickers between 1111 1111 1110 and 1111 1111 1111.

0 to 5 V Range: FS−1 LSB = 4.99878 V
0 to 10 V Range: FS−1 LSB = 9.99756 V

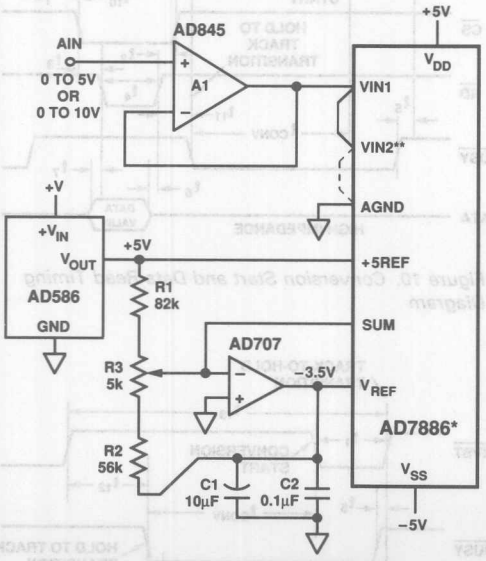

Figure 6. Unipolar Operation with Gain Error Adjust

BIPOLAR OPERATION

Bipolar operation is achieved by providing a +10 V span on the VIN1 input while offsetting the VIN2 input by +5 V. A typical circuit is shown in Figure 7. The output code is offset binary. The ideal input/output transfer characteristic is shown in Figure 8. The LSB size is (10/4096) V = 2.44 mV.

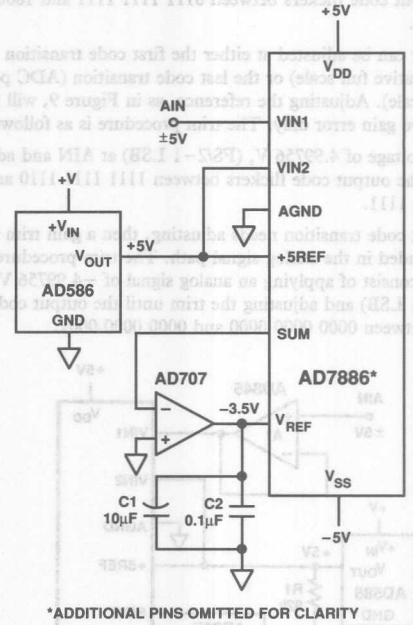

Figure 7. Bipolar Operation

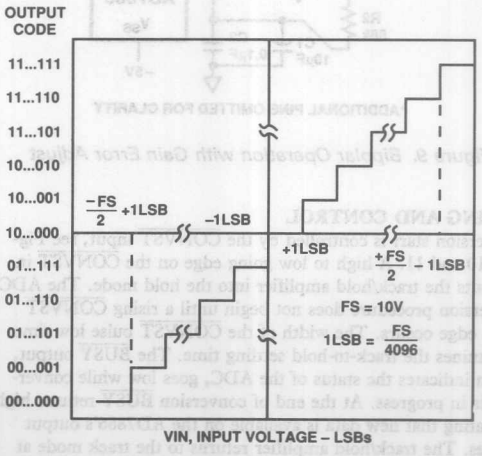

Figure 8. Ideal Input/Output Characteristics for Bipolar Operation

BIPOLAR OFFSET AND GAIN ADJUSTMENT

In applications where absolute accuracy is important then offset and gain error can be adjusted to zero. Offset is adjusted by trimming the voltage at the VIN1 or VIN2 input when the analog input is at zero volts. This can be achieved by adjusting the offset of an external amplifier used to drive either of these inputs, see A1 in Figure 9. The trim procedure is as follows:

Apply zero volts at AIN and adjust the offset of A1 until the ADC output code flickers between 0111 1111 1111 and 1000 0000 0000.

Gain error can be adjusted at either the first code transition (ADC negative full scale) or the last code transition (ADC positive full scale). Adjusting the reference, as in Figure 9, will trim the positive gain error only. The trim procedure is as follows:

Apply a voltage of 4.99756 V, (FS/2−1 LSB) at AIN and adjust R3 until the output code flickers between 1111 1111 1110 and 1111 1111 1111.

If the first code transition needs adjusting, then a gain trim has to be included in the analog signal path. The trim procedure will then consist of applying an analog signal of −4.99756 V, (−FS/2+1 LSB) and adjusting the trim until the output code flickers between 0000 0000 0000 and 0000 0000 0001.

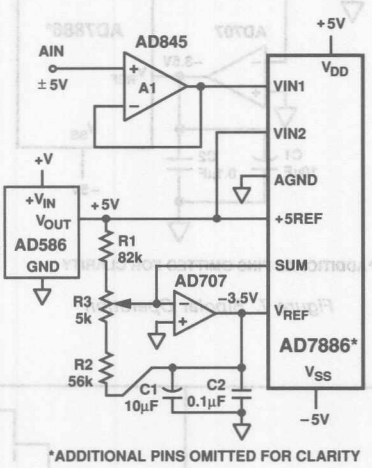

Figure 9. Bipolar Operation with Gain Error Adjust

TIMING AND CONTROL

Conversion start is controlled by the $\overline{\text{CONVST}}$ input, see Figures 10 and 11. A high to low going edge on the $\overline{\text{CONVST}}$ input puts the track/hold amplifier into the hold mode. The ADC conversion procedure does not begin until a rising $\overline{\text{CONVST}}$ pulse edge occurs. The width of the $\overline{\text{CONVST}}$ pulse low time determines the track-to-hold settling time. The $\overline{\text{BUSY}}$ output, which indicates the status of the ADC, goes low while conversion is in progress. At the end of conversion $\overline{\text{BUSY}}$ returns high indicating that new data is available on the AD7886's output latches. The track/hold amplifier returns to the track mode at the end of conversion and remains there until the next $\overline{\text{CONVST}}$ pulse. Conversion starts must not be attempted while conversion is in progress as this will cause erroneous results.

Data read operations are controlled by the $\overline{\text{CS}}$ and $\overline{\text{RD}}$ inputs. These digital inputs, when low, enable the AD7886's three-state output latches. Note, these latches cannot be enabled during conversion. In applications where $\overline{\text{CS}}$ and $\overline{\text{RD}}$ are tied permanently low, as in Figure 11, the data bus will go into the three-state condition at the start of conversion and return to its active state when conversion is complete. Tying $\overline{\text{CS}}$ and $\overline{\text{RD}}$ permanently low is useful when external latches are used to store the conversion results. The data bus becomes active before $\overline{\text{BUSY}}$ returns high at the end of conversion, so that $\overline{\text{BUSY}}$ can be used as a clocking signal for the external latches.

A typical DSP application would have a timer connected to the $\overline{\text{CONVST}}$ input for precise sampling intervals. $\overline{\text{BUSY}}$ would be connected to the interrupt of a microprocessor which would be asserted at the end of every conversion. The microprocessor would then assert the $\overline{\text{CS}}$ and $\overline{\text{RD}}$ inputs and read the data from the ADC. For applications where both data reading and conversion control need to be managed by a microprocessor, then a $\overline{\text{CONVST}}$ pulse can be decoded from the address bus. One decoding possibility is that a write instruction to the ADC address starts a conversion and a read instruction reads the conversion result.

AD7886 DYNAMIC SPECIFICATIONS

The AD7886 is specified for dynamic performance specifications as well as traditional dc specifications such as integral and differential nonlinearity. These ac specifications are required for the signal processing applications such as speech recognition, spectrum analysis, and high speed modems. These applications require information on the ADC's effect on the spectral content of the input signal. Hence, the parameters for which the AD7886 is specified include SNR, harmonic distortion, intermodulation distortion and peak harmonics. These terms are discussed in more detail in the following sections.

Signal-to-Noise Ratio (SNR)

SNR is the measured signal-to-noise ratio at the output of the ADC. The signal is the rms magnitude of the fundamental. Noise is the rms sum of all the nonfundamental signals up to half the sampling frequency (FS/2) excluding dc. SNR is dependent upon the number of quantization levels used in the digitization process; the more levels, the smaller the quantization noise. The theoretical signal to noise ratio for a sine wave input is given by

$$SNR = (6.02N + 1.76)\ dB \quad (1)$$

where N is the number of bits. Thus for an ideal 12-bit converter, SNR = 74dB.

The output spectrum from the ADC is evaluated by applying a sine wave signal of very low distortion to the VIN input which is sampled at a 750 kHz sampling rate. A Fast Fourier Transform (FFT) plot is generated from which the SNR data can be obtained. Figure 12 shows a typical 2048 point FFT plot with an input signal of 100 kHz and a sampling frequency of 750 kHz. The SNR obtained from this graph is 68 dB. It should be noted that the harmonics are taken into account when calculating the SNR.

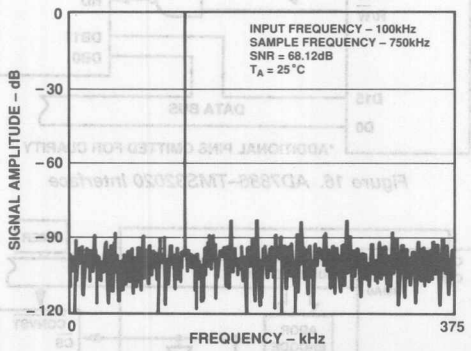

Figure 12. AD7886 FFT Plot

Effective Number of Bits

The formula given in Equation 1 relates the SNR to the number of bits. Rewriting the formula, as in Equation 2, it is possible to get a measure of performance expressed in effective number of bits (N).

$$N = \frac{SNR - 1.76}{6.02} \quad (2)$$

The effective number of bits for a device can be calculated directly from its measured SNR.

Figure 13 shows a typical plot of effective number of bits versus frequency for a sampling frequency of 750 kHz. Input frequency range for this particular graph was limited by the test equipment to FS/4. The effective number of bits typically falls between 10.9 and 11.2 corresponding to SNR figures of 67.38 dB and 69.18 dB.

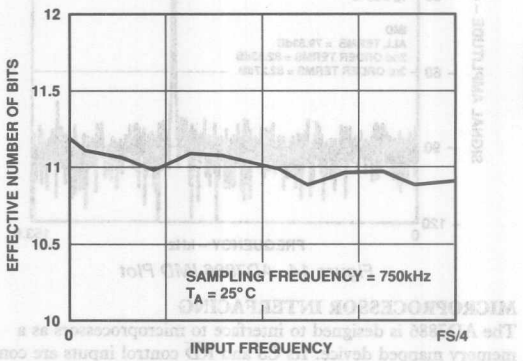

Figure 13. Effective Number of Bits vs. Frequency

Total Harmonic Distortion (THD)

THD is the ratio of the rms sum of harmonics to the fundamental. For the AD7886, THD is defined as

$$THD = 20\ log \frac{\sqrt{V_2^2 + V_3^2 + V_4^2 + V_5^2 + V_6^2}}{V_1} \quad (3)$$

where V_1 is the rms amplitude of the fundamental and V_2, V_3, V_4, V_5 and V_6 are the rms amplitudes of the second through to the sixth harmonic. The THD is also derived from the FFT plot of the ADC output spectrum.

Intermodulation Distortion (IMD)

With inputs consisting of sine waves at two frequencies, fa and fb, any active device with nonlinearities will create distortion products at sum and difference frequencies of mfa± nfb where m,n = 0, 1, 2, 3, etc. Intermodulation terms are those for which neither m or n are equal to zero. For example, the second order terms include (fa + fb) and (fa − fb) while the third order terms include (2fa + fb), (2fa − fb), (fa + 2fb) and (fa − 2fb).

Using the CCIF standard where two input frequencies near the top end of the input bandwidth are used, the second and third order terms are of different significance. The second order terms are usually distanced in frequency from the original sine waves, while the third order terms are usually at a frequency close to the input frequencies. As a result, the second and third order terms are specified separately. The calculation of the intermodulation distortion is as per the THD specification where it is the ratio of the rms sum of the individual distortion products to the rms amplitude of the fundamental expressed in dBs. In this case, the input consists of two, equal amplitude, low distortion sine waves. Figure 14 shows a typical IMD plot for the AD7886.

Peak Harmonic or Spurious Noise

Peak harmonic or spurious noise is defined as the ratio of the rms value of the next largest component in the ADC output spectrum (up to FS/2 and excluding dc) to the rms value of the fundamental. Normally, the value of this specification will be

parts where the harmonics are buried in the noise floor the peak will be a noise peak.

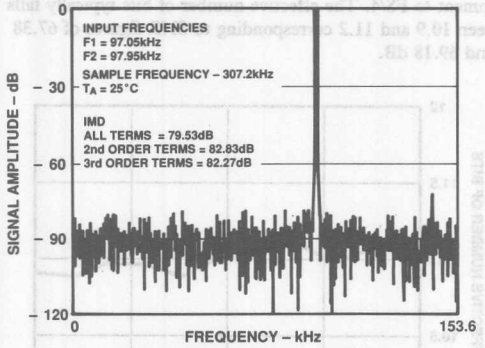

Figure 14. AD7886 IMD Plot

MICROPROCESSOR INTERFACING

The AD7886 is designed to interface to microprocessors as a memory mapped device. Its $\overline{CS}$ and $\overline{RD}$ control inputs are common to all memory peripheral interfacing. Figures 15 to 21 demonstrate typical interfaces for the AD7886.

AD7886–TMS320C10/TMS32020

Figures 15 and 16 show typical interfaces for the TMS320C10 and the TMS32020 DSP processors. An external timer controls conversion start to the processor. At the end of each conversion the ADC's $\overline{BUSY}$ output interrupts the microprocessor. The conversion result can then be read from the ADC with the following instruction:

IN D,ADC (ADC = ADC address)

AD7886– ADSP-2100/TMS320C25/DSP56000

Some of the faster DSP processors have data access times which are outside the capabilities of the AD7886. Interfacing to such processors requires the use of either a single WAIT state or external latches. Examples are shown in Figures 17, 18 and 19.

The use of a single WAIT state for the TMS320C25 and the ADSP-2100 interfaces extends the read instruction to the ADC by one processor CLK OUT cycle. In the DSP56000 example the ADC's data is first clocked into 74HC374 latches before being read by the processor. The AD7886's $\overline{CS}$ and $\overline{RD}$ inputs are tied permanently low, and the rising edge of $\overline{BUSY}$ updates the latches at the end of conversion. Both methods of overcoming the very fast data access time required by these processors are interchangeable, i.e., a WAIT state can be used for the DSP56000 eliminating the need for latches or vice versa for the other two interfaces.

For all three interfaces, an external timer controls conversion start, the processor is interrupted at the end of each conversion by the ADC's $\overline{BUSY}$ output. The following instruction then reads data from the ADC:

ADSP-2100 – MR = DM(ADC)
TMS320C25 – IN D,ADC
DSP56000 – MOVEP Y:ADC,XO

Assuming the ADC is memory mapped into the top 64 locations in Y memory space.
(ADC = ADC address)

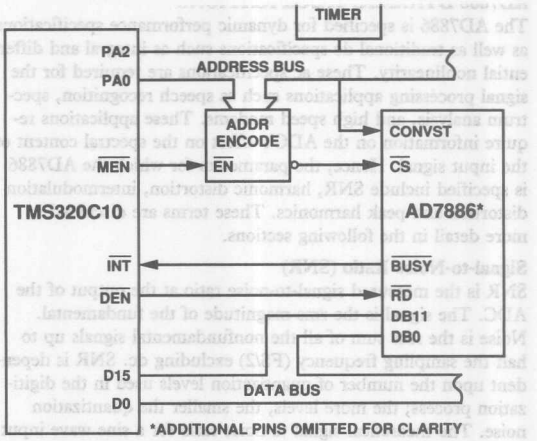

Figure 15. AD7886–TMS320C10 Interface

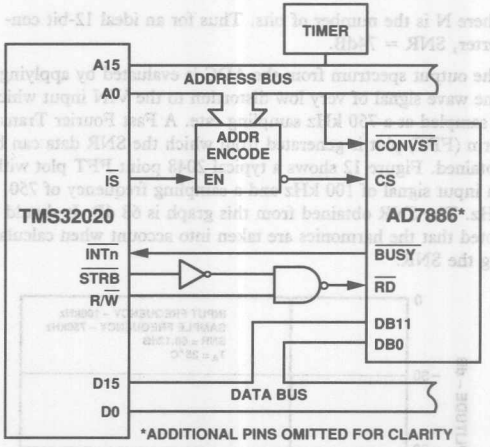

Figure 16. AD7886–TMS32020 Interface

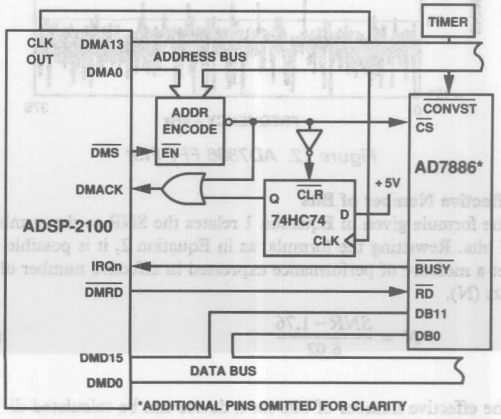

Figure 17. AD7886–ADSP-2100 Interface

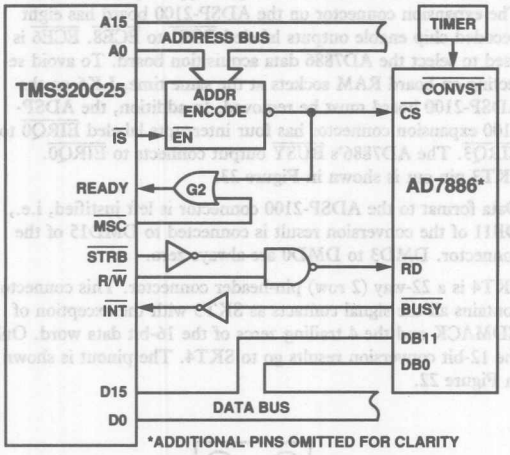

Figure 18. AD7886–TMS320C25 Interface

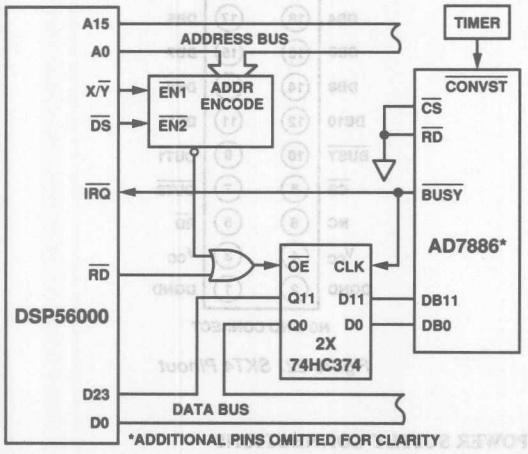

Figure 19. AD7886–DSP56000 Interface

AD7886–MC68000

Applications that require conversions to be initiated by the microprocessor rather than an external timer may decode a $\overline{\text{CONVST}}$ signal from the address bus. An example is given in Figure 20 with the MC68000 processor. A write instruction starts conversion while a read instruction reads the data when conversion is complete. A delay at least as long as the ADC conversion time must allowed between initiating a conversion and reading the ADC data into the processor. In Figure 20, $\overline{\text{BUSY}}$ is used to drive the processor into a WAIT state if the processor attempts to read data before conversion is complete.

Conversion is initiated with a write instruction to the ADC:

Move.W D0,ADC (ADC = ADC address)

Data is transferred to the processor with a read instruction, $\overline{\text{BUSY}}$ will force the processor to WAIT for the end of conversion if a conversion is in progress.

Move.W ADC,DO (ADC = ADC address)

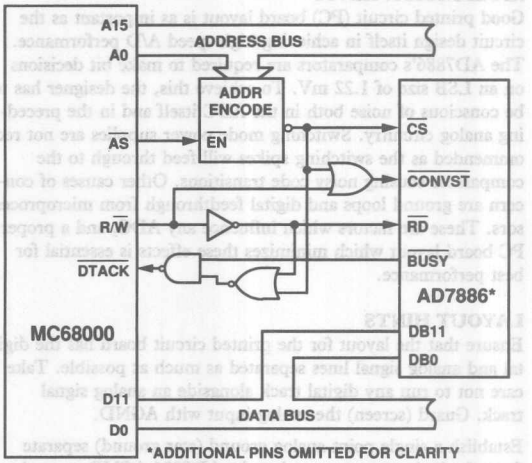

Figure 20. AD7886–MC68000 Interface

AD7886–Z-80/8085A

For 8-bit processors an external latch is required to store 4-bits of the conversion result (4 LSBs in Figure 21). The data is then read in two bytes: one read from the ADC and a second from the latch.

Figure 21 shows a typical interface that is suitable for the Z-80 or the 8085A. Not shown in the Figure is the 8-bit latch needed to demultiplex the 8085A common address/data bus. The following LOAD instruction reads the conversion result into the HL register pair.

For the 8085A – LHLD (ADC) (ADC = ADC address)
For the Z-80–LDHL (ADC) (ADC = ADC address)

This is a two byte read instruction. The first byte to be read has to be the high byte (DB11 to DB4). At the end of the first read operation, the rising edge of $\overline{\text{CS}}$ and $\overline{\text{RD}}$ clocks the 4 LSBs into 74HC374 latches. The second byte (4 LSBs) is then read from these latches.

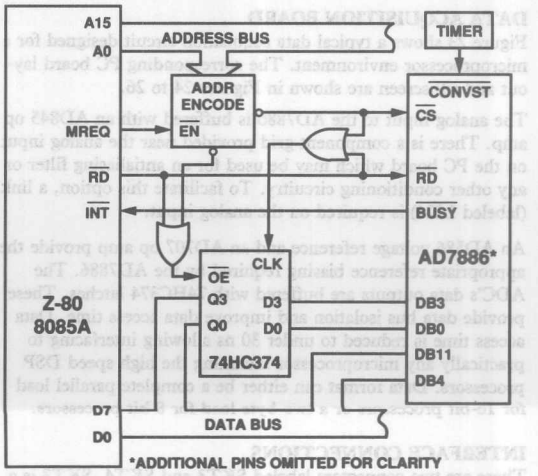

Figure 21. AD7886–Z-80/8085A Interface

APPLICATION HINTS

Good printed circuit (PC) board layout is as important as the circuit design itself in achieving high speed A/D performance. The AD7886's comparators are required to make bit decisions on an LSB size of 1.22 mV. To achieve this, the designer has to be conscious of noise both in the ADC itself and in the preceding analog circuitry. Switching mode power supplies are not recommended as the switching spikes will feed through to the comparator causing noisy code transitions. Other causes of concern are ground loops and digital feedthrough from microprocessors. These are factors which influence any ADC, and a proper PC board layout which minimizes these effects is essential for best performance.

LAYOUT HINTS

Ensure that the layout for the printed circuit board has the digital and analog signal lines separated as much as possible. Take care not to run any digital track alongside an analog signal track. Guard (screen) the analog input with AGND.

Establish a single point analog ground (star ground) separate from the logic system ground at the AD7886 AGND or as close as possible to the AD7886. Connect all other grounds and the AD7886 DGND to this single analog ground point. Do not connect any other digital grounds to this analog ground point.

Low impedance analog and digital power supply common returns are essential to low noise operation of the ADC, so make the foil width for these tracks as wide as possible. The use of ground planes minimizes impedance paths and also guards the analog circuitry from digital noise. The circuit layout of Figures 25 and 26 have both analog and digital ground planes which are kept separated and only joined together at the AD7886 AGND.

NOISE

Keep the input signal leads to VIN and signal return leads from AGND as short as possible to minimize input noise coupling. In applications where this is not possible, use a shielded cable between the source and the ADC. Reduce the ground circuit impedance as much as possible since any potential difference in grounds between the signal source and the ADC appears as an error voltage in series with the input signal.

DATA ACQUISITION BOARD

Figure 23 shows a typical data acquisition circuit designed for a microprocessor environment. The corresponding PC board layout and silkscreen are shown in Figures 24 to 26.

The analog input to the AD7886 is buffered with an AD845 op amp. There is a component grid provided near the analog input on the PC board which may be used for an antialiasing filter or any other conditioning circuitry. To facilitate this option, a link (labeled LK4) is required on the analog input.

An AD586 voltage reference and an AD707 op amp provide the appropriate reference biasing required by the AD7886. The ADC's data outputs are buffered with 74HC374 latches. These provide data bus isolation and improve data access time. Data access time is reduced to under 30 ns allowing interfacing to practically any microprocessor including the high speed DSP processors. Data format can either be a complete parallel load for 16-bit processors or a two-byte load for 8-bit processors.

INTERFACE CONNECTIONS

There are two connectors labeled SKT3 and SKT4. SKT3 is a 96-contact (3-row) connector which is directly compatible with the ADSP-2100 evaluation board prototype expansion connector. The expansion connector on the ADSP-2100 board has eight decoded chip enable outputs labeled $\overline{\text{ECE1}}$ to $\overline{\text{ECE8}}$. $\overline{\text{ECE6}}$ is used to select the AD7886 data acquisition board. To avoid selecting on-board RAM sockets at the same time, LK6 on the ADSP-2100 board must be removed. In addition, the ADSP-2100 expansion connector has four interrupts labeled $\overline{\text{EIRQ0}}$ to $\overline{\text{EIRQ3}}$. The AD7886's $\overline{\text{BUSY}}$ output connects to $\overline{\text{EIRQ0}}$. SKT3 pin out is shown in Figure 23.

Data format to the ADSP-2100 connector is left justified, i.e., DB11 of the conversion result is connected to DMD15 of the connector. DMD3 to DMD0 are always zero.

SKT4 is a 22-way (2 row) pin-header connector. This connector contains all the signal contacts as SKT3 with the exception of EDMACK and the 4 trailing zeros of the 16-bit data word. Only the 12-bit conversion results go to SKT4. The pinout is shown in Figure 22.

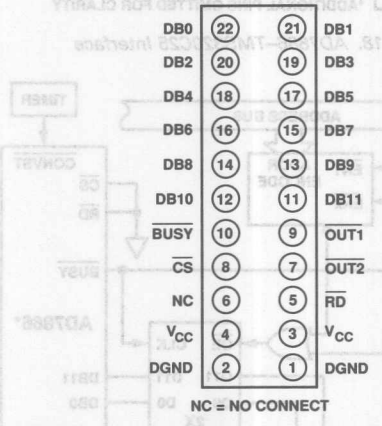

Figure 22. SKT4 Pinout

POWER SUPPLY CONNECTIONS

The PC board requires two analog power supplies and one 5 V digital supply. Connections to the analog supply are made directly to the PC board as shown on the silkscreen in Figure 24. The connections are labeled V+ and V−, and the range for both of these supplies is 12 V to 15 V. Connection to the 5 V digital supply is made through either of the two connectors (SKT3 or SKT4). The ±5 V analog supplies required by the AD7886 are generated from voltage regulators on the V− and V+ power supplies.

LINK OPTIONS

There are five link options, labeled LK1 to LK5 which must be set before using the board.

LK1 Input Range Select

The AD7886 can accommodate three possible analog input ranges: 0 to 5 V, 0 to 10 V and ±5 V. The link options are as follows:

0 to 5 V	Use Link C
0 to 10 V	Use Link B
±5 V	Use Link A

LK2 and LK3 Control Input Options

The evaluation board includes two latches to increase the data access time when interfacing to the faster DSP machines. If these latches are not required, they may be removed and the data digital paths shorted out, i.e., latch inputs Dx shorted to outputs Qx using wire links in the latch sockets. When using the latches, the AD7886 control inputs, $\overline{CS}$ and $\overline{RD}$, must be tied low via links 2 and 3. The latches are updated by the rising edge of the $\overline{BUSY}$ signal at the end of every conversion. Data is then read by asserting the latch output enable signals. The alternative is to remove the latches and assert the ADC's control inputs from either of the connectors, SKT3 or SKT4, as outlined in the data sheet.

Latches Included	Latches Removed
Insert Link 2	Remove Link 2
Insert Link 3	Remove Link 3

LK4 Analog Input Option

LK4 connects the analog input to a component grid or to a buffer amplifier which drives the ADC input.

LK5

Data format can be 16-bits parallel or two bytes for 8-bit processors. There are two data enable controls for the 74HC374 latches, labeled $\overline{OUT1}$ and $\overline{OUT2}$. $\overline{OUT1}$ enables the 8 MSBs (IC8), and $\overline{OUT2}$ enables the 4 LSBs (IC9). Link options are: for 16-bit format, include LK5 and for a two byte read format, remove LK5.

LC²MOS 8-Channel, 12-Bit Serial, Data Acquisition System

AD7890

FEATURES

- Fast 12-Bit ADC with 10 μs Conversion Time
- Eight Single-Ended Analog Input Channels
- ±10 V Input Range
- Allows Separate Access to Multiplexer and ADC
- On-Chip Track/Hold Amplifier
- High Speed, Flexible, Serial Interface
- Single Supply Operation
- Low Power, 50 mW max in Normal Operation
- Power-Down Mode

FUNCTIONAL BLOCK DIAGRAM

GENERAL DESCRIPTION

The AD7890 is an eight-channel 12-bit data acquisition system. The part contains an input multiplexer, an on-chip track/hold amplifier, a high speed 12-bit ADC and a high speed serial interface. The part operates from a single +5 V supply and accepts an analog input range of ±10 V.

The multiplexer on the part is independently accessible. This allows the user to insert an antialiasing filter, if required, between the multiplexer and the ADC. This means that one antialiasing filter can be used for all eight channels. Connection of an external capacitor allows the user to adjust the time given to the multiplexer settling to include any external delays in this antialiasing filter.

Output data from the AD7890 is provided via a high speed bidirectional serial interface port. The part contains an on-chip control register, allowing control of channel selection, conversion start, power-down, etc., via the serial port. Versatile, high speed logic ensures easy interfacing to serial ports on microcontrollers and digital signal processors.

In addition to the traditional dc accuracy specifications such as linearity, full-scale and offset errors, the AD7890 is also specified for dynamic performance parameters including harmonic distortion and signal-to-noise ratio.

Power dissipation in normal mode is low at 30 mW typ, and the part can be placed in a standby (power-down) mode if it is not required to performed conversions. The AD7890 is fabricated in Analog Devices' Linear Compatible CMOS (LC²MOS) process, a mixed technology process that combines precision bipolar circuits with low power CMOS logic. The part is available in a 24-pin, 0.3" wide, plastic or hermetic dual-in-line package or in a 24-pin small outline package (SOIC).

PRODUCT HIGHLIGHTS

1. Complete 12-Bit Data Acquisition System on a Chip
   The AD7890 is a complete monolithic ADC combining an eight-channel multiplexer, 12-bit ADC and a track/hold amplifier on a single chip.
2. Separate Access to Multiplexer and ADC
   The AD7890 provides access to the output of the multiplexer allowing the user to insert an antialiasing filter between the multiplexer and the ADC. This allows one antialiasing filter for eight channels—a considerable saving over the eight antialiasing filters required if the multiplexer was internally connected to the ADC.
3. High Speed Serial Interface
   The part provides a high speed serial interface for easy connection to serial ports of microcontrollers and DSP processors. An on-chip control register is programmed via this bidirectional serial port.

PIN FUNCTION DESCRIPTION

Pin Mnemonic	Description
V_{IN1}–V_{IN8}	Analog Input Channels. These input channels provide eight single-ended inputs. The analog input range on each channel is ±10 V. The channel to be converted is selected using the A0, A1 and A2 bits in the control register. The multiplexer has guaranteed break-before-make operation.
MUX OUT	Multiplexer Output. The output of the multiplexer appears at this pin. The output voltage range from this output is 0 to +2.5 V for a ±10 V analog input to the selected channel. The output impedance of this output is nominally 3.5 kΩ. If no external antialiasing filter is required, MUX OUT should be connected to SHA IN.
SHA IN	Track/Hold Input. The input to the on-chip track/hold is applied to this pin. It is a high impedance input, and the input voltage range is 0 V to +2.5 V.
REF IN	Voltage Reference Input. The reference voltage for the part is applied to this pin. The input impedance of this reference input varies with the analog input voltage and REF IN should, therefore, be driven from a low impedance source. The nominal reference voltage for correct operation of the AD7890 is +2.5 V.
V_{DD}	Positive supply voltage, +5 V ± 5%.
AGND	Analog Ground. Ground reference for track/hold, comparator and DAC.
DGND	Digital Ground. Ground reference for digital circuitry.
SCLK	Serial Clock Input. In the external clocking (slave) mode (see DIGITAL INTERFACE section) this is an externally applied serial clock which is used to load serial data to the control register and to access data from the output register. In the self-clocking (master) mode, the internal serial clock, which is derived from the clock input (CLK IN), appears on this pin. Once again, it is used to load serial data to the control register and to access data from the output register.
$\overline{TFS}$	Transmit Frame Synchronization Pulse. Active low logic input with serial data expected after the falling edge of this signal.
DATA IN	Serial Data Input. Serial data to be loaded to the control register is provided at this input. The first six bits of serial data are loaded to the control register on the first six falling edges of SCLK after $\overline{TFS}$ goes low. Serial data on subsequent SCLK edges is ignored while $\overline{TFS}$ remains low.
$\overline{RFS}$	Receive Frame Synchronization Pulse. In the external clocking mode, this pin is an active low logic input with $\overline{RFS}$ provided externally as a strobe or framing pulse to access serial data from the output register. In the self-clocking mode, it is an active low output which is internally generated and provides a strobe or framing pulse for serial data from the output register. For applications which require that data be transmitted and received at the same time, $\overline{RFS}$ and $\overline{TFS}$ should be connected together.
DATA OUT	Serial Data Output. Sixteen bits of serial data are provided with one leading zero, preceeding the three address bits of the Control register and the 12-bits of conversion data. Serial data is valid on the falling edge of SCLK for sixteen edges after $\overline{RFS}$ goes low. Output coding from the ADC is 2s complement.
$\overline{CONVST}$	Convert Start. Edge-triggered logic input. A low to high transition on this input puts the track/hold into hold and initiates conversion provided that the internal one-shot has timed out (see Control Register section). If the internal pulse is active when the $\overline{CONVST}$ goes high, the track/hold will not go into hold until the pulse times out. If the internal pulse has timed out when $\overline{CONVST}$ goes high, the rising edge of $\overline{CONVST}$ drives the track/hold into hold and initiates conversion.
CLK IN	Clock Input. An external TTL-compatible clock is applied to this input pin to provide the clock source for the conversion sequence. In the self-clocking serial mode, the SCLK output is derived from this CLK IN pin.
C_{EXT}	External Capacitor. An external capacitor is connected to this pin to determine the length of the internal one-shot pulse (see $\overline{CONVST}$ input and Control Register section). Larger capacitances on this pin extend the pulse to allow for settling-time delays through an external antialiasing filter or signal conditioning circuitry.
NC	No Connect. Do not connect anything to this pin.

PRELIMINARY TECHNICAL DATA

This information applies to a product under development. Its characteristics and specifications are subject to change without notice. Analog Devices assumes no obligation regarding future manufacture unless otherwise agreed to in writing.

A2	A1	A0	CONV	SC/EC	STBY

A2 Address Input. This input is the most significant address input for multiplexer channel selection.

A1 Address Input. This is the 2nd most significant address input for multiplexer channel selection.

A0 Address Input. Least significant address input for multiplexer channel selection. When the address is written to the control register, an internal one-shot is initiated, the pulse width of which is determined by the value of capacitance on the C_{EXT} pin. When this pulse is active, it ensures the conversion process cannot be activated. This allows an external antialiasing filter (the output of which appears at SHA IN) to settle before the track/hold goes into hold and conversion is initiated. When this pulse times out, the track/hold goes into hold and conversion is initiated.

CONV Conversion Start. Writing a 1 to this bit initiates a conversion in a similar manner to the $\overline{\text{CONVST}}$ input. Continuous conversion starts do not take place when there is a 1 in this location. The internal one-shot and the conversion process are initiated on the next clock edge after a 1 is written to this bit. With a 1 in this bit, the hardware conversion start, i.e., the $\overline{\text{CONVST}}$ input, is disabled. Writing a 0 to this bit enables the hardware $\overline{\text{CONVST}}$ input.

SC/EC Master/Slave Selection. Writing a 0 to this bit puts the AD7890 into its self-clocking (master) mode where the SCLK and $\overline{\text{RFS}}$ pins are outputs and the AD7890 effectively acts as a master in a serial system. This self-clocking mode is useful for connection to shift registers and the serial ports of DSP processors. Writing a 1 to this bit puts the AD7890 serial interface into its external clocking (slave) mode where the SCLK and $\overline{\text{RFS}}$ pins are both inputs and the AD7890 effectively acts as a slave to a microprocessor in a serial system. This external clocking mode is useful for connection to the serial port of microcontrollers such as the 8XC51 and the 68HCXX and for connection to the serial ports of DSP processors. The AD7890 powers up in its external clocking mode.

STBY Standby Mode Input. Writing a 1 to this bit places the device in its standby or power-down mode. Writing a 0 to this bit places the device in its normal operating mode.

PRELIMINARY TECHNICAL DATA

CIRCUIT DESCRIPTION

The AD7890 is an eight-channel, 12-bit serial data acquisition system. It provides the user with signal scaling, multiplexer, track/hold, A/D converter and versatile serial logic functions on a single chip. The signal scaling allows the part to handle ±10 V input signals while operating from a single +5 V supply. The part requires an external +2.5 V external reference.

Unlike other single chip solutions, the AD7890 provides the user with separate access to the multiplexer and the A/D converter. This means that the flexibility of separate multiplexer and ADC solutions is not sacrificed with the one-chip solution. With access to the multiplexer output, the user can implement external signal conditioning between the multiplexer and the track/hold. It means that one antialiasing filter can be used to on the output of the multiplexer to provide the antialiasing function for all eight channels. The extra settling time introduced into the circuit by the external circuitry can be allowed for by the AD7890 by connecting a single capacitor to the C_{EXT} pin. If no external signal conditioning is required, the multiplexer output (MUX OUT) can simply be connected directly to the track/hold input (SHA IN).

A serial write to the control register selects the input channel to be converted. When the three address bits are written to the control register, an internal pulse is initiated. This disables the track/hold from going into hold and also disables conversion from being initiated. The duration of the internal pulse allows for the settling time of the on-chip multiplexer. By connecting different values of capacitor for the C_{EXT} pin, this internal pulse can be stretched to cater for the settling time of external components between the MUX OUT and SHA IN pins.

Once the pulse has been timed out, conversion can be initiated on the A/D converter. The conversion can be initiated by pulsing the $\overline{\text{CONVST}}$ input or by writing to the CONV bit of the Control Register. If the conversion start command is coincident with the multiplexer write or occurs while the internal pulse is active, the track/hold will not go into hold and conversion will not be initiated until the internal pulse has timed out.

The AD7890 provides separate channel select and conversion start control. This allows the user to optimize the throughput rate of the system. Once the track/hold has gone into hold mode the input channel can be updated and the input voltage can settle to the new value while the present conversion is in progress.

This information applies to a product under development. Its characteristics and specifications are subject to change without notice. Analog Devices assumes no obligation regarding future manufacture unless otherwise agreed to in writing.

DIGITAL INTERFACE

The AD7890's serial communications port provides a flexible arrangement to allow easy interfacing to industry standard microprocessors, microcontrollers and digital signal processors. A serial read to the AD7890 accesses data from the output register via the DATA OUT line. A serial write to the AD7890 writes data to the Control Register via the DATA IN line.

Two different modes of operation are available, optimized for different types of interface where the AD7890 can either act as master in the system (it provides the serial clock and data framing signal) or act as slave (an external serial clock and framing signal can be provided to the AD7890). These two modes, labelled self-clocking mode and external clocking mode, are discussed in detail in the following sections. Note, the AD7890 powers up in its external clocking mode. A Logic 0 must be written to the SC/EC bit of the control register to place the part in its self-clocking mode.

Self-Clocking Mode

The AD7890 is configured for its self-clocking mode by writing a 0 to the SC/EC bit of the control register. In this mode, the AD7890 provides the serial clock signal and the serial data framing signal used for the transfer of data from the AD7890. This self-clocking mode can be used with processors which allow an external device to clock their serial port including most digital signal processors.

Read Operation

Figure 1 shows a timing diagram for reading from the AD7890 in the self-clocking mode. At the end of conversion, $\overline{RFS}$ goes low and the serial clock (SCLK) and serial data (DATA OUT) outputs become active. Sixteen bits of data are transmitted with one leading zero, followed by the three address bits of the Control Register, followed by the 12 bit conversion result starting with the MSB. Serial data is clocked out of the device on the rising edge of SCLK and is valid on the falling edge of SCLK. The $\overline{RFS}$ output remains low for the duration of the sixteen clock cycles. When $\overline{RFS}$ returns high, the serial clock and serial data outputs are disabled.

Write Operation

Figure 2 shows a write operation to the Control Register of the AD7890. The $\overline{TFS}$ input goes low to indicate to the part that a serial write is about to occur. $\overline{TFS}$ going low initiates the SCLK output, and this is used to clock data out of the processors serial port and into the Control Register of the AD7890. The AD7890 Control Register requires only six bits of data. These are loaded on the first six clock cycles of the serial clock with data on all subsequent clock cycles being ignored. Serial data to be written to the AD7890 must be valid on the falling edge of SCLK.

PRELIMINARY TECHNICAL DATA

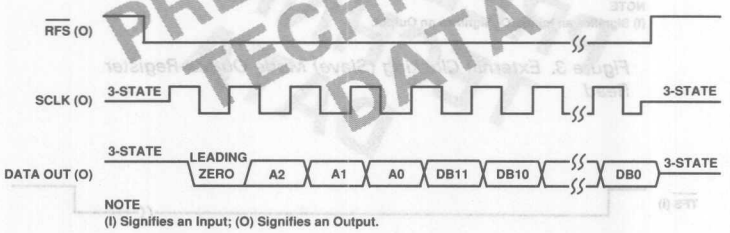

Figure 1. Self-Clock (Master) Mode Output Register Read

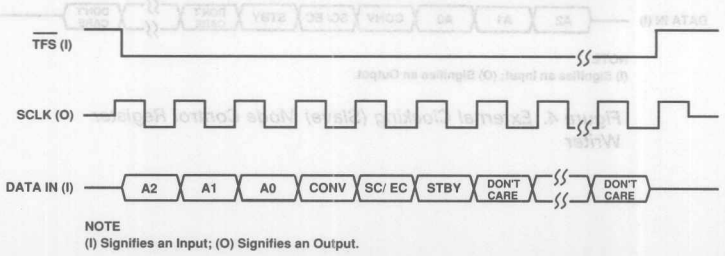

Figure 2. Self-Clocking (Master) Mode Control Register Write

This information applies to a product under development. Its characteristics and specifications are subject to change without notice. Analog Devices assumes no obligation regarding future manufacture unless otherwise agreed to in writing.

External Clocking Mode

The AD7890 is configured for its external clocking mode by writing a 1 to the SC/EC bit of the Control Register. In this mode, SCLK and $\overline{RFS}$ of the AD7890 are configured as inputs. This external-clocking mode is designed for direct interface to systems which provide a serial clock output which is synchronized to the serial data output including microcontrollers such as the 80C51, 87C51, 68HC11 and 68HC05 and most digital signal processors.

Read Operation

Figure 3 shows the timing diagram for reading from the AD7890 in the external clocking mode. $\overline{RFS}$ goes low to access data from the AD7890. The serial clock input does not have to be continuous. The serial data can be accessed in a number of bytes. However, $\overline{RFS}$ must remain low for the duration of the data transfer operation. Once again, sixteen bits of data are transmitted with one leading zero, followed by the three address bits in the Control Register, followed by the 12-bit conversion result starting with the MSB. Serial data is clocked out of the device on the rising edge of SCLK and is valid on the falling edge of SCLK. If a serial read from the output register is in progress when conversion is complete, the updating of the output register is deferred until the serial data read is complete.

Write Operation

Figure 4 shows a write operation to the Control Register of the AD7890. As with the self-clocking mode, the $\overline{TFS}$ input goes low to indicate to the part that a serial write is about to occur. The AD7890 control register requires only six bits of data. These are loaded on the first six clock cycles of the serial clock with data on all subsequent clock cycles being ignored. Serial data to be written to the AD7890 must be valid on the falling edge of SCLK.

LC²MOS 8-Channel, 12-Bit Parallel Data Acquisition System

AD7891

FEATURES

- Fast 12-Bit ADC with 10 μs Conversion Time
- Eight Single-Ended Analog Input Channels
- ±10 V Input Range
- Allows Separate Access to Multiplexer and ADC
- On-Chip Track/Hold Amplifier
- High Speed Parallel Interface
- Single Supply Operation
- Low Power, 50 mW max in Normal Operation
- Power-Down Mode

FUNCTIONAL BLOCK DIAGRAM

GENERAL DESCRIPTION

The AD7891 is an 8-channel 12-bit data acquisition system with a parallel interface structure. The part contains an input multiplexer, an on-chip track/hold amplifier, a high speed 12-bit ADC and a high speed parallel interface. The part operates from a single +5 V supply and accepts an analog input range of ±10 V.

The multiplexer on the part is independently accessible. This allows the user to insert an antialiasing filter, if required, between the multiplexer and the ADC. This means that one antialiasing filter can be used for all eight channels. Connection of an external capacitor allows the user to adjust the time given to the multiplexer settling to include any external delays in this antialiasing filter.

The AD7891 has standard control inputs and fast data access times which ensure easy interfacing to modern microprocessors and digital signal processors.

In addition to the traditional dc accuracy specifications such as linearity, full-scale and offset errors, the part is also specified for dynamic performance parameters including harmonic distortion and signal-to-noise ratio.

Power dissipation in normal mode is low at 30 mW typ, while in the standby mode this is reduced to 1 mW typ. The AD7891 is fabricated in Analog Devices' Linear Compatible CMOS (LC²MOS) process, a mixed technology process that combines precision bipolar circuits with low power CMOS logic. The part is available in a 44-pin plastic quad flat-pack (PQFP) and a 44-lead ceramic quad flat pack (CERQUAD).

PRODUCT HIGHLIGHTS

1. Complete 12-Bit Data Acquisition System on a Chip
   The AD7891 is a complete monolithic ADC combining an 8-channel multiplexer, 12-bit ADC and a track/hold amplifier on a single chip.
2. Separate Access to Multiplexer and ADC
   The AD7891 provides access to the output of the multiplexer allowing the user to insert an antialiasing filter between the multiplexer and the ADC. This allows one antialiasing filter for eight channels—a considerable saving over the eight antialiasing filters required if the multiplexer were internally connected to the ADC.
3. Fast Microprocessor Interface
   The part offers a high speed, parallel interface for easy connection to microprocessors, 16-bit microcontrollers and digital signal processors.

PIN FUNCTION DESCRIPTION

Pin Mnemonic	Description
V_{IN1}–V_{IN8}	Analog Input Channels. These input channels provide eight single-ended inputs. The analog input range for each channel is ±10 V. The channel to be converted is selected by the A2, A1 and A0 inputs. The multiplexer has guaranteed break-before-make operation.
MUX OUT	Multiplexer Output. The output of the multiplexer appears at this pin. The output voltage range from this output is 0 to +2.5 V for a ±10 V analog input to the selected channel. The output impedance of this output is nominally 3.5 kΩ. If no external antialiasing filter is required, MUX OUT should be connected to SHA IN.
SHA IN	Track/Hold Input. The input to the on-chip track/hold is applied to this pin. It is a high impedance input and the input voltage range is 0 V to +2.5 V.
REF IN	Voltage Reference Input. The reference voltage for the part is applied to this pin. The input impedance of this reference input varies with the analog input voltage and REF IN should, therefore, be driven from a low impedance source. The nominal reference voltage for correct operation of the AD7891 is +2.5 V.
V_{DD}	Positive Supply Voltage, +5 V ±5%.
AGND	Analog Ground. Ground reference for track/hold, comparator and DAC.
DGND	Digital Ground. Ground reference for digital circuitry.
A0	Address Input. Least significant address input for multiplexer channel selection.
A1	Address Input. This is the 2nd most significant address input for multiplexer channel selection.
A2	Address Input. This input is the most significant address input for multiplexer channel selection.
$\overline{WR}$	Write Input. Edge-triggered, active low, logic input which latches the multiplexer address. The rising edge of this input also initiates an internal one-shot, the pulse width of which is determined by the value of capacitance on the C_{EXT} pin. When this pulse is active, it ensures the conversion process cannot be activated. This allows an external antialiasing filter (the output of which is applied to SHA IN) to settle before the track/hold goes into hold and conversion is initiated. If the $\overline{CONVST}$ input goes high , either coincident with the $\overline{WR}$ input or during the internal pulse active time, the track/hold will not go from track to hold and conversion will not be initiated until the internal pulse times out. When this pulse times out, the track/hold then goes into hold and conversion is initiated. If the pulse has timed out prior to $\overline{CONVST}$ going high, the rising edge of $\overline{CONVST}$ will put the track/hold into hold and initiate conversion.
$\overline{CONVST}$	Convert Start. Edge-triggered logic input. A low to high transition on this input puts the track/hold into hold and initiates conversion, provided that the internal one-shot has timed out (see $\overline{WR}$ input). If the internal pulse is active when the $\overline{CONVST}$ goes high, the track/hold will not go into hold until the internal pulse times out. If the internal pulse has timed out when $\overline{CONVST}$ goes high, the rising edge of $\overline{CONVST}$ drives the track/hold into hold and initiates conversion.
$\overline{CS}$	Chip Select. Active low logic input which is used in conjunction with $\overline{RD}$ to enable the data outputs.
$\overline{RD}$	Read. Active low logic input which is used in conjunction with $\overline{CS}$ low to enable the data outputs.
EOC	End-of-Conversion. Active low logic output indicating converter status. The end of conversion is signified by a low-going pulse on this line. The duration of this EOC pulse is nominally 500 ns.
CLK IN	Clock Input. An external TTL-compatible clock may be applied to this input pin to provide the clock source for the conversion sequence.
C_{EXT}	External Capacitor. An external capacitor is connected to this pin to determine the length of the internal one-shot pulse (see $\overline{WR}$ input). Larger capacitances on this pin extend the pulse to allow for settling-time delays through the external antialiasing filter.
$\overline{STANDBY}$	Standby Mode Input. TTL-compatible input which is used to put the device into the power save or standby mode. The STANDBY input is high for normal operation and low for standby operation.
DB0–DB11	Data Bit 0 (LSB) to Data Bit 11 (MSB). Three-state TTL-compatible outputs. Output data coding from the AD7891 is 2s complement.
NC	No Connect. Do not connect anything to this pin.

PRELIMINARY DATA

This information applies to a product under development. Its characteristics and specifications are subject to change without notice. Analog Devices assumes no obligation regarding future manufacture unless otherwise agreed to in writing.

CIRCUIT DESCRIPTION

The AD7891 is an 8-channel, 12-bit parallel data acquisition system. It provides the user with signal scaling, multiplexer, track/hold, A/D converter and high speed parallel interface logic functions on a single chip. The signal scaling allows the part to handle ±10 V input signals while operating from a single +5 V supply. The part requires an external +2.5 V external reference.

Unlike other single chip solutions, the AD7891 provides the user with separate access to the multiplexer and the A/D converter. This means that the flexibility of separate multiplexer and ADC solutions is not sacrificed with the one chip solution. With access to the multiplexer output, the user can implement external signal conditioning between the multiplexer and the track/hold. It means that one antialiasing filter can be used on the output of the multiplexer to provide the antialiasing function for all eight channels. The extra settling time introduced into the circuit by the external circuitry can be allowed for by the AD7891 by connecting a single capacitor to the C_{EXT} pin. If no external signal conditioning is required, the multiplexer output (MUX OUT) can simply be connected directly to the track/hold input (SHA IN).

A write to the multiplexer address inputs (A0, A1, A2) selects the input channel to be converted. When the three address bits are written to the part, an internal pulse is initiated. This disables the track/hold from going into hold and also disables conversion from being initiated. The duration of the internal pulse allows for the settling time of the on-chip multiplexer. By connecting different values of capacitor for the C_{EXT} pin, this internal pulse can be stretched to cater for the settling-time of external components between the MUX OUT and SHA IN pins.

Once the pulse has been timed out, conversion can be initiated on the A/D converter. The conversion is initiated by pulsing the $\overline{CONVST}$ input. If the conversion start command is coincident with the multiplexer write or occurs while the internal pulse is active, the track/hold will not go into hold and conversion will not be initiated until the internal pulse has timed out.

The AD7891 provides separate channel select and conversion start control. This allows the user to optimize the throughput rate of the system. Once the track/hold has gone into hold mode, the input channel can be updated and the input voltage can settle to the new value while the present conversion is in progress.

INTERFACE INFORMATION

Figure 1 shows a timing diagram illustrating the operational sequence of the AD7891. The multiplexer address is written to the AD7891 on the rising edge of the $\overline{WR}$ input. The on-chip track/hold goes into hold mode on the rising edge of $\overline{CONVST}$, and conversion is also initiated at this point. When conversion is complete, the end of conversion line ($\overline{EOC}$) pulses low to indicate that new data is available in the AD7891's output register. This $\overline{EOC}$ line can be used to drive an edge-triggered interrupt of a microprocessor. $\overline{CS}$ and $\overline{RD}$ going low accesses the 12-bit conversion result. In stand-alone systems, the $\overline{EOC}$ pulse can be applied to the $\overline{CS}$ and $\overline{RD}$ inputs to latch data out of the AD7891 and into an external latch or gate array.

LC²MOS
Single Supply, 12-Bit, 5.5 µs ADC
AD7892

FEATURES

Fast 12-Bit ADC with 5.5 µs Conversion Time
Single Supply Operation
On-Chip Track/Hold Amplifier
±10 V Input Range
High Speed Serial and Parallel Interface
Low Power, 50 mW

FUNCTIONAL BLOCK DIAGRAM

PRELIMINARY TECHNICAL DATA

GENERAL DESCRIPTION

The AD7892 is a high speed, low power, 12-bit A/D converter which operates from a single +5 V supply. The part contains a 5.5 µs successive approximation ADC, an on-chip track/hold amplifier and on-chip versatile interface structures which allow both serial and parallel connection to a microprocessor. The part accepts an analog input range of ±10 V.

The AD7892 offers a choice of two data output formats: a single, parallel, 12-bit word or serial data. Fast bus access times and standard control inputs ensure easy parallel interface to microprocessors and digital signal processors. A high speed flexible serial interface allows direct connection to shift registers and to the serial ports of microcontrollers and digital signal processors.

In addition to the traditional dc accuracy specifications such as linearity, full-scale and offset errors, the part is also specified for dynamic performance parameters including harmonic distortion and signal-to-noise ratio.

The part operates from a single +5 V supply and accepts ±10 V input signals. Power dissipation for the part is low at 30 mW typical.

The AD7892 is fabricated in Analog Devices' Linear Compatible CMOS (LC²MOS) process, a mixed technology process that combines precision bipolar circuits with low power CMOS logic. It is available in a 24-pin, 0.3" wide, plastic or hermetic dual-in-line package or in a 24-pin small outline package (SOIC).

PRODUCT HIGHLIGHTS

1. Fast Conversion Time
   The AD7892 features a conversion time of 5.5 µs and a track/hold acquisition time of 1.5 µs. This allows a throughput rate in excess of 140 kHz and an input bandwidth in excess of 70 kHz.
2. Single Supply Operation
   The AD7892 operates from a single +5 V supply and consumes only 30 mW making it ideal for low power and portable applications.
3. Fast, Versatile Microprocessor Interface
   The part offers a high speed, flexible interface arrangement with parallel and serial interfaces for easy connection to microprocessors, microcontrollers and digital signal processors.

This information applies to a product under development. Its characteristics and specifications are subject to change without notice. Analog Devices assumes no obligation regarding future manufacture unless otherwise agreed to in writing.

PRELIMINARY TECHNICAL DATA

This information applies to a product under development. Its characteristics and specifications are subject to change without notice. Analog Devices assumes no obligation regarding future manufacture unless otherwise agreed to in writing.

Pin Mnemonic	Description
V_{IN}	Analog Input. The analog input range is ±10 V.
REFIN	Voltage Reference Input. The reference voltage for the part is applied to this pin. The input impedance of this reference input varies with the analog input voltage and REFIN should, therefore, be driven from a low impedance source. The nominal reference voltage for correct operation of the AD7892 is +2.5 V.
V_{DD}	Positive Supply Voltage, +5 V ±5%.
AGND	Analog Ground. Ground reference for track/hold, comparator and DAC.
DGND	Digital Ground. Ground reference for digital circuitry.
$\overline{CONVST}$	Convert Start. Logic Input. A low to high transition on this input puts the track/hold into its hold mode and starts conversion.
$\overline{CS}$	Chip Select. Active low logic input which is used in conjunction with $\overline{RD}$ to enable the data outputs.
$\overline{RD}$	Read. Active low logic input which is used in conjunction with $\overline{CS}$ low to enable the data outputs.
EOC	End-of-Conversion. Active low logic output indicating converter status. The end of conversion is signified by a low going pulse on this line. The duration of this EOC pulse is nominally 500 ns.
CLK	Clock Input. The external TTL-compatible clock is applied to this input pin to provide the clock source for the conversion sequence.
MODE	Mode. Control input which determines the interface mode for the AD7892. With this pin at a logic low, the device is in its serial interface mode; with this pin at a logic high, the device is in its parallel interface mode.
DB0-DB7	Data Bit 0 (LSB) to Data Bit 7. Three-state TTL-compatible outputs. Output coding is 2s complement. These outputs should be left unconnected when the device is in its serial mode.
DB8/SMODE	Data Bit 8/Serial Mode. When the device is in its parallel mode, this pin is Data Bit 8, a three-state TTL-compatible output. When the device is in its serial mode, this becomes a control input which determines whether the part operates in its External Clocking (slave) or Self-Clocking (master) serial mode. With SMODE at a logic high, the part is in its Self-Clocking serial mode with $\overline{RFS}$ and SCLK as outputs. This Self-Clocking mode is useful for connection to shift registers or to the serial ports of DSP processors. With SMODE at a logic low, the part is in its External Clocking serial mode with SCLK and $\overline{RFS}$ as inputs. This External Clocking mode is useful for connection to the serial port of microcontrollers such as the 8XC51 and the 68HCXX and for connection to the serial port of DSP processors.
DB9/$\overline{RFS}$	Data Bit 9/Receive Frame Synchronization. When the device is in its parallel mode, this pin is Data Bit 9, a three-state TTL-compatible output. When the device is in its serial mode, this becomes the receive frame synchronization pulse which can be either an input or an output depending on the status of SMODE. With SMODE at a logic high, the part is in its Self-Clocking mode and $\overline{RFS}$ is internally generated by the device and is provided as an output to frame the valid serial data. With SMODE at a logic low, the part is in its External Clocking serial mode with $\overline{RFS}$ provided externally to obtain serial data from the AD7892.
DB10/SDATA	Data Bit 10/Serial Data. When the device is in its parallel mode, this pin is Data Bit 10, a three-state TTL-compatible output. When the device is in its serial mode, this becomes the serial data output line. Sixteen bits of serial data are provided with four leading zeros preceding the 12-bits of valid data. Serial data is valid on the falling edge of SCLK for sixteen edges after $\overline{RFS}$ goes low. Output coding is 2s complement.
DB11/SCLK	Data Bit 11/Serial Clock. When the device is in its parallel mode, this pin is Data Bit 11(MSB), a three-state TTL-compatible output. When the device is in its serial mode, this becomes the serial clock pin which is an input or an output depending on the status of SMODE. With SMODE at a logic high, SCLK is generated internally from the CLK input and is provided as an output. With SMODE at a logic low, SCLK is an input and an external serial clock must be provided at this pin to obtain serial data from the AD7892. Regardless of the status of SMODE, serial data is valid on the falling edge of SCLK for sixteen edges after $\overline{RFS}$ goes low.
NC	No Connect. Do not connect anything to this pin.

PRELIMINARY TECHNICAL DATA

This information applies to a product under development. Its characteristics and specifications are subject to change without notice. Analog Devices assumes no obligation regarding future manufacture unless otherwise agreed to in writing.

CIRCUIT DESCRIPTION

The AD7892 is a fast, 12-bit single supply A/D converter. It provides the user with signal scaling, track/hold, A/D converter and versatile interface logic functions on a single chip. The signal scaling allows the part to handle ±10 V input signals while operating from a single +5 V supply. The part requires an external +2.5 V external reference.

Conversion is initiated on the AD7892 by pulsing the $\overline{\text{CONVST}}$ input. On the rising edge of $\overline{\text{CONVST}}$, the on-chip track/hold goes from track to hold mode and the conversion sequence is started. Conversion time for the AD7892 is 5.5 μs and the track/hold acquisition time is 1.5 μs. This allows the part to operate at throughput rates up to 140 kHz, while the input track/hold can handle input bandwidths in excess of the Nyquist criterion of 70 kHz.

INTERFACING

The part provides three interface options, one parallel and two serial. The parallel interface mode is selected by tying the MODE input to a logic high. The serial modes are selected by tying this pin to a logic low. With the MODE pin low, the DB8/SMODE, DB9/$\overline{\text{RFS}}$, DB10/SDATA and DB11/SCLK pins all assume their serial mode functions. SMODE becomes a logic input which selects whether the AD7892 operates in its Self-Clocking serial mode or in its External-Clocking serial mode. The three interface modes are discussed in the following sections.

Parallel Interface Mode

Figure 1 shows a timing diagram illustrating the operational sequence of the AD7892. The on-chip track/hold goes into hold mode on the rising edge of $\overline{\text{CONVST}}$ and conversion is also initiated at this point. When conversion is complete, the end of conversion line (EOC) pulses low to indicate that new data is available in the AD7892's output register. This EOC line can be used to drive an edge-triggered interrupt of a microprocessor. $\overline{\text{CS}}$ and $\overline{\text{RD}}$ going low accesses the 12-bit conversion result. In stand-alone systems, the EOC pulse can be applied to the $\overline{\text{CS}}$ and $\overline{\text{RD}}$ inputs to latch data out of the AD7892 and into an external latch or gate array.

PRELIMINARY TECHNICAL DATA

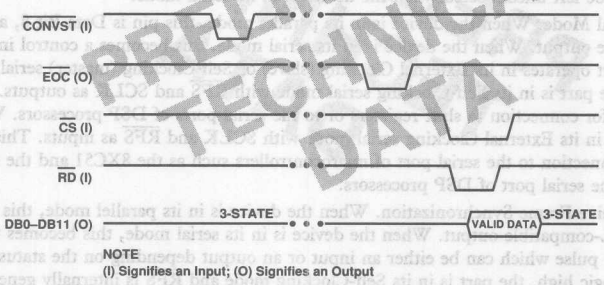

Figure 1. Parallel Mode Timing Diagram

This information applies to a product under development. Its characteristics and specifications are subject to change without notice. Analog Devices assumes no obligation regarding future manufacture unless otherwise agreed to in writing.

SERIAL INTERFACE

The AD7892 is configured for serial mode interfacing by tying the MODE input low. The AD7892's serial communications port provides a flexible arrangement to allow easy interfacing to industry-standard microprocessors, microcontrollers and digital signal processors. It provides for a three-wire, serial link between the AD7892 and the microprocessor. Two different modes of operation are available, optimized for different types of interface where the AD7892 can act either as master in the system (it provides the serial clock and data framing signal) or acts as slave (an external serial clock and framing signal can be provided to the AD7892). These two modes, labelled Self-Clocking mode and External Clocking mode, are discussed in detail in the following sections.

Self-Clocking Mode

The AD7892 is configured for its self-clocking mode by tying the SMODE input high. In this mode, the AD7892 provides the serial clock signal and the serial data framing signal used for the transfer of data from the AD7892. This self-clocking mode can be used with processors which allow an external device to clock their serial port including most digital signal processors.

Figure 2 shows a timing diagram for reading from the AD7892 in the self-clocking mode. At the end of conversion, $\overline{RFS}$ goes low and the serial clock (SCLK) and serial data (SDATA) outputs become active. Sixteen bits of data are transmitted with four leading zeros followed by the 12 bit conversion result starting with the MSB. Serial data is clocked out of the device on the rising edge of SCLK and is valid on the falling edge of SCLK. The $\overline{RFS}$ output remains low for the duration of the 16 clock cycles. When $\overline{RFS}$ returns high, the serial clock and serial data outputs are disabled.

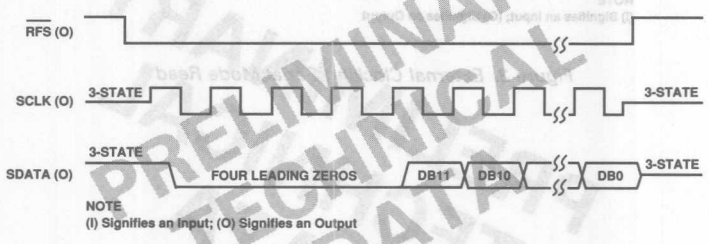

Figure 2. Self-Clocking Serial Mode Read

PRELIMINARY TECHNICAL DATA

This information applies to a product under development. Its characteristics and specifications are subject to change without notice. Analog Devices assumes no obligation regarding future manufacture unless otherwise agreed to in writing.

External-Clocking Mode

The AD7892 is configured for its external-clocking mode by tying the SMODE input to a logic low. In this mode, SCLK and $\overline{RFS}$ of the AD7892 are configured as inputs. This external-clocking mode is designed for direct interface to systems which provide a serial clock output which is synchronized to the serial data output including microcontrollers such as the 80C51, 87C51, 68HC11 and 68HC05 and most digital signal processors.

Figure 3 shows the timing diagram for reading from the AD7892 in the external-clocking mode. $\overline{RFS}$ goes low to access data from the AD7892. The serial clock input does not have to be continuous. The serial data can be accessed in a number of bytes. However, $\overline{RFS}$ must remain low for the duration of the data transfer operation. Once again, 16 bits of data are transmitted with 4 leading zeros followed by the 12 bit conversion result starting with the MSB. Serial data is clocked out of the device on the rising edge of SCLK and is valid on the falling edge of SCLK. If a serial read from the output register is in progress when conversion is complete, the updating of the output register is deferred until the serial data read is complete.

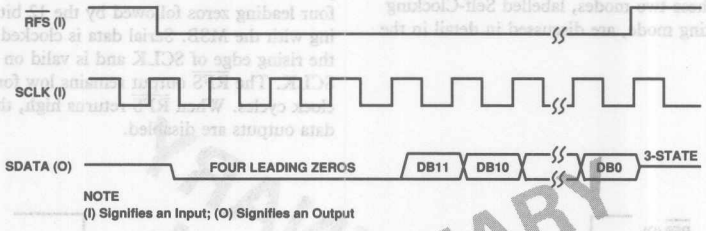

Figure 3. External Clocking Serial Mode Read

LC²MOS 12-Bit, Serial 5.5 µs, ADC in 8-Pin Package

AD7893

FEATURES

Fast 12-Bit ADC with 5.5 µs Conversion Time
8-Pin Mini-DIP and SOIC
Single Supply Operation
High Speed, Easy-to-Use, Serial Interface
On-Chip Track/Hold Amplifier
±10 V Input Range
Low Power, 50 mW max

FUNCTIONAL BLOCK DIAGRAM

PRELIMINARY TECHNICAL DATA

GENERAL DESCRIPTION

The AD7893 is a fast, 12-bit ADC which operates from a single +5 V supply and is housed in a small 8-pin mini-DIP and 8-pin SOIC. The part contains a 5.5 µs successive approximation A/D converter, an on-chip track/hold amplifier, an on-chip clock and a high speed serial interface.

Output data from the AD7893 is provided via a high speed, serial interface port. This two-wire serial interface has a serial clock input and a serial data output with the external serial clock accessing the serial data from the part.

In addition to the traditional dc accuracy specifications such as linearity, full-scale and offset errors, the AD7893 is also specified for dynamic performance parameters including harmonic distortion and signal-to-noise ratio.

The part accepts an analog input range of ±10 V and operates from a single +5 V supply consuming only 30 mW.

The AD7893 is fabricated in Analog Devices' linear compatible CMOS (LC²MOS) process, a mixed technology process that combines precision bipolar circuits with low power CMOS logic. The part is available in a small, 8-pin, 0.3″ wide, plastic or hermetic dual-in-line package (mini-DIP) and in an 8-pin, small-outline IC (SOIC).

PRODUCT HIGHLIGHTS

1. Fast, 12-Bit ADC in 8-Pin Package
   The AD7893 contains a 5.5 µs ADC, a track/hold amplifier, control logic and a high speed serial interface, all in an 8-pin DIP. This offers considerable space saving over alternative solutions.
2. Low Power, Single Supply Operation
   The AD7893 operates from a single +5 V supply and consumes only 30 mW. This low power, single supply operation makes it ideal for battery-powered or portable applications.
3. High Speed Serial Interface
   The part provides high speed serial data and serial clock lines allowing for an easy, two-wire serial interface arrangement.

This information applies to a product under development. Its characteristics and specifications are subject to change without notice. Analog Devices assumes no obligation regarding future manufacture unless otherwise agreed to in writing.

PIN FUNCTION DESCRIPTION

Pin Mnemonic	Description
V_{IN}	Analog Input. The analog input range is ±10 V.
REF IN	Voltage Reference Input. The reference voltage for the part is applied to this pin. The input impedance of this reference input varies with the analog input voltage and REFIN should, therefore, be driven from a low impedance source. The nominal reference voltage for correct operation of the AD7893 is +2.5 V.
V_{DD}	Positive Supply Voltage, +5 V ±5%.
AGND	Analog Ground. Ground reference for track/hold, comparator and DAC.
DGND	Digital Ground. Ground reference for digital circuitry.
SCLK	Serial Clock Input. An external serial clock is applied to this input to obtain serial data from the AD7893. A new serial data bit is clocked out on the rising edge of this serial clock and data is valid on the falling edge. The serial clock input should be taken low at the end of the serial data transmission.
SDATA	Serial Data Output. Serial data from the AD7893 is provided at this output. The serial data is clocked out by the rising edge of SCLK and is valid on the falling edge of SCLK. Sixteen bits of serial data are provided with four leading zeros followed by the 12-bits of conversion data. The last bit of serial data clocked out in a read cycle (on the sixteenth rising edge of SCLK) will remain on the SDATA line until the next serial data word is accessed.
$\overline{\text{CONVST}}$	Convert Start. Edge-triggered logic input. A low to high transition on this input puts the track/hold into its hold mode and starts conversion.

CIRCUIT DESCRIPTION

The AD7893 is a fast, 12-bit single supply A/D converter. It provides the user with signal scaling, track/hold, A/D converter and serial interface logic functions on a single chip. The signal scaling allows the part to handle ±10 V input signals while operating from a single +5 V supply. The AD7893 consumes only 30 mW typical making it ideal for battery-powered applications.

The part requires an external +2.5 V external reference. This reference input should be driven from a low impedance source as the input current to the REFIN pin varies with the analog input voltage.

A major advantage of the AD7893 is that it provides all of the above functions in an 8-pin package, either 8-pin mini-DIP or SOIC. This offers the user considerable spacing saving advantages over alternative solutions.

Conversion is initiated on the AD7893 by pulsing the $\overline{\text{CONVST}}$ input. On the rising edge of $\overline{\text{CONVST}}$, the on-chip track/hold goes from track-to-hold mode and the conversion sequence starts. Conversion time for the AD7893 is 5.5 μs and the track/hold acquisition time is 1.5 μs. This allows the part to operate at throughput rates up to 140 kHz, while the input track/hold can handle input bandwidths in excess of the Nyquist criterion of 70 kHz.

PRELIMINARY TECHNICAL DATA

This information applies to a product under development. Its characteristics and specifications are subject to change without notice. Analog Devices assumes no obligation regarding future manufacture unless otherwise agreed to in writing.

Serial Interface

The serial interface to the AD7893 consists of just two wires, a serial clock input (SCLK) and the serial data output (SDATA). This allows for an easy-to-use interface to most microcontrollers, DSP processors and shift registers.

Figure 1 shows the timing diagram for a read operation to the AD7893. The serial clock input (SCLK) provides the clock source for the serial interface. Serial data is clocked out from the SDATA line on the rising edge of this clock and is valid on the falling edge of SCLK. Sixteen clock pulses must be provided to the part to access to full conversion result. The AD7893 provides four leading zeros followed by the 12-bit conversion result starting with the MSB (DB11). The last data bit to be clocked out on the final rising clock edge is the LSB (DB0). This bit will remain on the SDATA line until the next serial data read is performed to the AD7893. After this last bit has been clocked out, the SCLK input should return low and remain low until the next serial data read operation.

The serial clock input does not have to be continuous during the serial read operation. The 16 bits of data (4 leading zeros and 12-bit conversion result) can be read from the AD7893 in a number of bytes. However, the SCLK input must remain low between the two bytes.

If a serial read from the output register is in progress when conversion is complete, the updating of the output register is deferred until the serial read is completed.

AD9000

FEATURES
77MSPS Encode Rate
Bipolar Input Range
Low Error Rate
Overflow Bit
MIL-STD-883 Compliant Versions Available

APPLICATIONS
QAM Telecommunications
Electronic Warfare (ECM, ECCM, ESM)
Radar Guidance Digitizers

FUNCTIONAL BLOCK DIAGRAM

GENERAL DESCRIPTION

The AD9000 is a 6-bit, high speed, analog-to-digital converter with ECL compatible outputs and a bipolar input stage. The AD9000 is fabricated in a high-performance bipolar process which allows encode rates up to 77MSPS.

The AD9000 employs the standard flash converter architecture based on 64 individual comparators which simultaneously determine the precise analog signal level. The comparators are followed by two stages of decoding logic, allowing the AD9000 to operate with a very low error rate. The low 35pF input capacitance of the AD9000 greatly simplifies the analog driver stage. Also incorporated into the AD9000 design is an overflow output bit as well as a hysteresis control pin to modify comparator sensitivity.

The AD9000 is offered as both an commercial temperature range device 0 to +70°C, and as an extended temperature range device −55°C to +125°C. Both versions are available packaged in a 16-pin ceramic DIP. The extended temperature range device is also available in a 28-pin ceramic LCC package. The extended temperature range versions are offered as fully compliant MIL-STD-883 Class B devices.

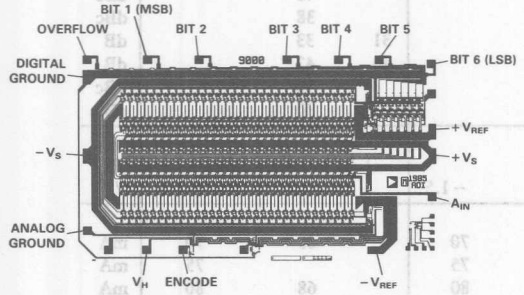
NOTES
[1]$A_{IN} = +V_{REF}$.
[2]Determined by 3dB reduction in reconstructed output at 75MSPS.
[3]Under normal operating conditions, the analog input voltages should not exceed nominal ±2V operating range, nor the supply voltages ($+V_S$ and $-V_S$), whichever is smaller.
[4]Under normal operating conditions the differential reference voltage may range from ±0.5V to ±2V; $+V_{REF} \geq -V_{REF}$.
[5]Output terminated with 100Ω resistors to −2.0V.
[6]Measured from the leading edge of ENCODE to data out on Bit 1 (MSB).
[7]Measured from the trailing edge of ENCODE to data out on Bit 1 (MSB).
[8]For full-scale step input, 6-bit accuracy is attained in specified time.
[9]Recovers to 6-bit accuracy in specified time, after 150% full-scale input overvoltage.
[10]Measured on Bit 1 (MSB) only.
[11]Measured at 50MSPS encode rate.
[12]Analog input frequency = 15MHz.
[13]RMS signal to RMS noise, with 540kHz analog input signal.
[14]Peak-to-peak signal to rms noise, with 540kHz analog input signal.
[15]$f_1 = 9.3$MHz; $f_2 = 7.6$MHz; Encode = 42MHz.
[16]DC to 8.2MHz noise bandwidth with 3.886MHz slot.
[17]Supply voltage should remain stable within ±5% for normal operation.

Specifications subject to change without notice.

ABSOLUTE MAXIMUM RATINGS[1]

Positive Supply Voltage	−0.3V to +6V
Negative Supply Voltage	−6.0V to +0.3V
Analog-to-Digital Ground Voltage Differential	0.5
Analog Input Voltages (A_{IN}, $+V_{REF}$, $-V_{REF}$)[2]	±3V
Differential Reference Voltage ($+V_{REF}$ to $-V_{REF}$)[3]	6V
ENCODE Input Voltage	$-V_S$ to 0V
HYSTERESIS Control Voltage	0V to +3.0V
Digital Output Current	20mA
Power Dissipation (+25°C Free Air)[4]	745mW
Operating Temperature Range	
AD9000JD	0 to +70°C
AD9000SD/SE	−55°C to +125°C
Storage Temperature Range	−65°C to +150°C
Junction Temperature	+175°C
Lead Soldering Temperature (10sec)	+300°C



NOTES
[1]Absolute maximum ratings are limiting values, to be applied individually, and beyond which serviceability of the circuit may be impaired. Functional operability under any of these conditions is not necessarily implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.
[2]Under normal operating conditions, the analog input voltages should not exceed nominal ±2V operating range, nor the supply voltages ($+V_S$ and $-V_S$), whichever is smaller.
[3]Under normal operating conditions the differential reference voltage may range from ±0.5V to ±2V; $+V_{REF} \geq -V_{REF}$.
[4]Typical thermal impedances . . .
16-Pin Ceramic $\theta_{ja} = 67°C/W$; $\theta_{jc} = 7°C/W$
28-Pin LCC $\theta_{ja} = 62°C/W$; $\theta_{jc} = 14°C/W$

ORDERING GUIDE

Model[1]	Temperature Range	Description	Package Option[2]

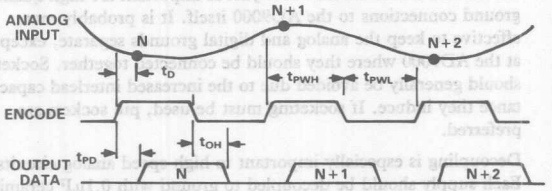
Substrate Potential	−VS
Passivation	10,000Å Oxynitride
Die Attach	Gold Eutectic
Bond Wire	1.25 mil Aluminum; Ultrasonic Bonding or 1mil Gold; Gold Ball Bonding

PIN DESIGNATIONS



FUNCTIONAL DESCRIPTION

PIN NAME	DESCRIPTION
−VS	Negative supply terminal, nominally −5.2V.
ANALOG GROUND	Analog ground return. All grounds should be connected together near the the AD9000.
VHYSTERESIS	The hysteresis control voltage varies the comparator hysteresis from 15mV to 50mV, for a change of 0V to +3V at the hysteresis control pin.
ENCODE	The ENCODE pin controls the conversion cycle. Encode is rising edge sensitive and should be driven with a 50% duty-cycle waveform under normal conditions.
−VREF	The most negative reference voltage for the internal resistor ladder.
ANALOG INPUT	Analog input pin.
+VS	Positive supply terminal, nominally +5.0V.
+VREF	Most positive reference voltage of the internal resistor ladder.
BIT 6 (LSB)	One of six digital outputs. BIT 6 (LSB) is the least-significant-bit of the digital output.
BIT 5 – BIT 2	One of six digital outputs.
BIT 1 (MSB)	One of six digital outputs. BIT1 (MSB) is the most-significant-bit of the digital output.
OVERFLOW	Overflow data output. Logic high indicates an input overvoltage ($A_{IN} \geq +V_{REF}$).
DIGITAL GROUND	Digital ground return. All grounds should be connected together near the AD9000.

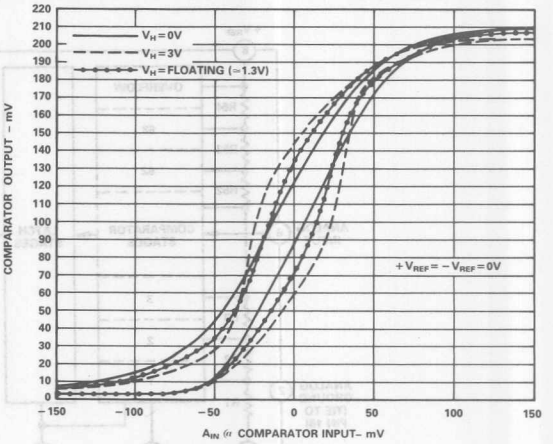
Burn-In Test Circuit

ABOUT THE AD9000

Analog Bandwidth

Quantifying the high-frequency analog performance of the AD9000 is somewhat difficult because of the various criteria that can be applied. At one extreme there is the analog input bandwidth of a single input comparator (which tends to be extremely high). At the other end of the performance criteria is the "no missing codes" restriction, which tends to be the most conservative measure of analog bandwidth.

The "no missing codes" criteria simply means that the converter is capable of generating all 64 output codes for an analog and ENCODE frequency. At higher ENCODE rates to analog frequencies, the converter continues to function, but with reduced resolution. The graph below details the "no missing codes" region of operation for the AD9000 at several reference levels. Note that nearly all analog-to-digital converter applications operate in the oversampled region to avoid generation of indeterminate data (aliasing).



Analog Input vs. Encode Rate "No Missing Codes"

High-Speed Performance Enhancements

The AD9000 employs a hysteresis control pin which affects comparator sensitivity. The error rate (number of full-scale errors in a given period) is directly affected by the comparator sensitivity. By varying the voltage on the hysteresis control pin, the error rate can be reduced. The AD9000 is capable of extremely low error rate operation, which makes it ideal for error sensitive applications like QAM demodulation. If the hysteresis control pin is used, it should be decoupled to ground through a 0.1μF capacitor, otherwise it may be left floating.

At the highest encode rates, overall accuracy can be improved by skewing the ENCODE signal duty-cycle to allow more time in the "latch" mode. Specifically, extending the logic HIGH portion of the ENCODE signal allows the comparators more time to achieve an appropriate logic level prior to the decoding cycle that begins on the rising edge of the ENCODE pulse.

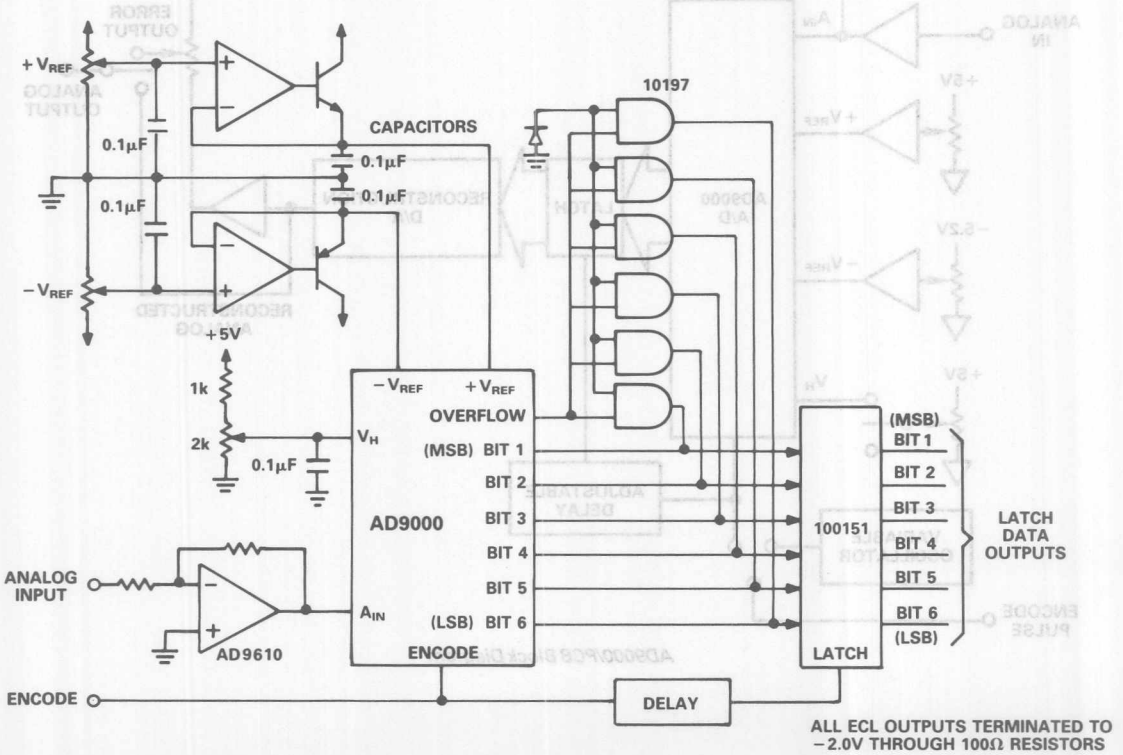
Comparator Switching vs. Hysteresis Voltage

Layout Considerations

The AD9000, like all high-speed circuits, requires certain precautions be taken to insure optimum performance. The foremost of these is the use of a substantial low impedance ground plane around and under the AD9000. Just as important are high quality ground connections to the AD9000 itself. It is probably more effective to keep the analog and digital grounds separate, except at the AD9000 where they should be connected together. Sockets should generally be avoided due to the increased interlead capacitance they induce. If socketing must be used, pin sockets are preferred.

Decoupling is especially important to high-speed analog circuits. Each supply should be decoupled to ground with 0.1μF ceramic and 0.001μF mica capacitors. The ladder reference pins should be treated in a similar manner. In addition to decoupling the reference ladder, the reference ladder should be driven from a low output impedance source for the best noise rejection. In all cases, chip capacitors are recommended, where practical, to reduce the effects of lead inductance associated with standard discrete capacitors.

MIL-STD-883 Compliance Information



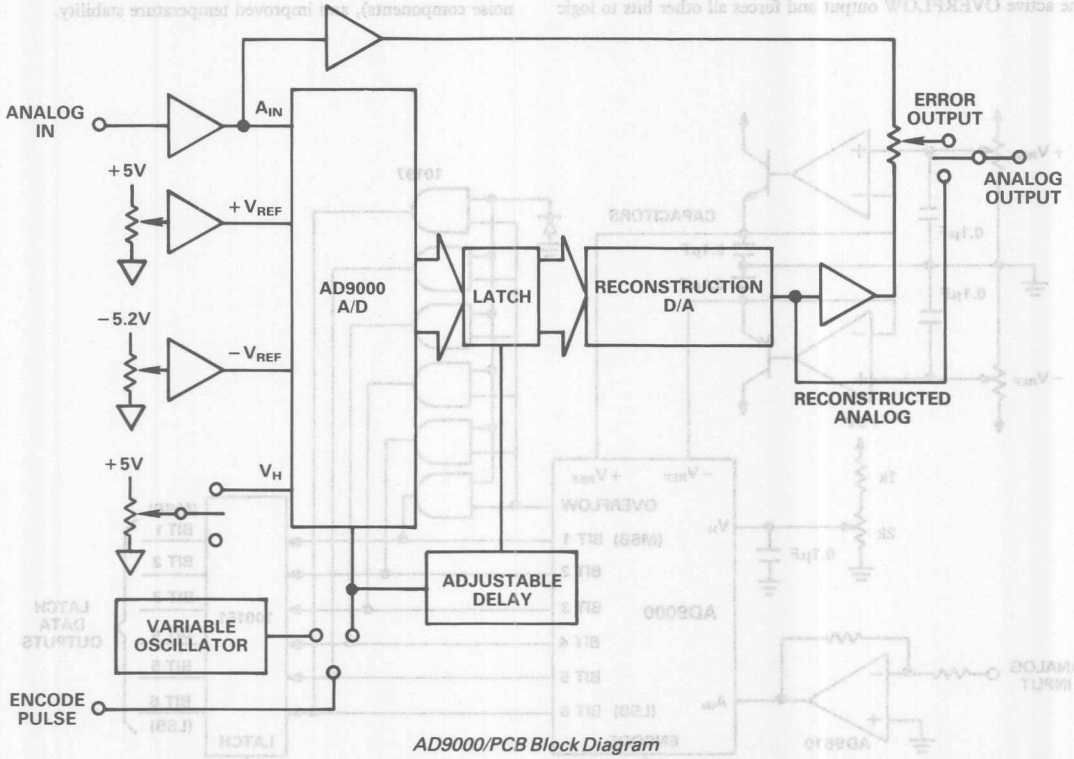
The AD9000SE/SD/883C are classified within microcircuits group 57-technology group D (bipolar A/D converters), and are constructed in accordance with the latest revision of MIL-STD-883. The AD9000 is electrostatic sensitive and falls within electrostatic sensitivity classification Category A. PDA (Percent Defective Allowance) is computed based of Subgroups 1 of the specified Group A test list. QA screening is in accordance with "Alternate Method A" of method 5005. The following apply: Burn-In per 1015, Life Test per 1005, Electrical Testing per 5004. (Note: Group A electrical Testing assumes $T_A = T_C = T_J$.)

TYPICAL APPLICATION

The AD9000 is a relatively flexible device which can be configured in a number of ways. One very useful feature of the AD9000 is the open emitter outputs. The open emitters allow the outputs of several AD9000s to be OR-WIRED in stacking applications for increased resolution. This kind of application depends on the return-to-zero nature of the output bits when $A_{IN} \geq +V_{REF}$ (overflow). In circuits which employ only one AD9000, this is not always an advantage. The circuit below illustrates one method of converting the outputs to nonreturn-to-zero.

The 10197 (standard 10K ECL logic) hex-AND group senses the active OVERFLOW output and forces all other bits to logic HIGH. The 10151 latch is not required for AD9000 applications, but it may ease data transfer sensitivities in asnychronous data collection systems.

The reference driver circuits should provide a low source impedance to prevent noise on the reference inputs from affecting the AD9000's accuracy. This is accomplished to a large extent by adequately decoupling the reference pins to ground. An improved method is employed below. The reference voltages ($+V_{REF}$, $-V_{REF}$) are buffered by a transistor/amplifier combination. This has the advantages of wide bandwidth (hence low impedance over a wide frequency range to eliminate high frequency noise components), and improved temperature stability.



AD9000/PCB EVALUATION AND TEST BOARD

Evaluating and testing the AD9000 is greatly simplified with the AD9000/PCB evaluation board. The printed circuit board contains all of the driver and buffering circuits needed to test and evaluate the AD9000. The board outputs include both a high quality reconstructed representation of the input waveform, and a dc error waveform output which can be used to determine device linearities.

Inputs to the AD9000/PCB evaluation board include the analog signal to be digitized, as well as an optional ENCODE input for high stability measurements. All components, except the AD9000, are soldered onto the 8.5″ × 6.3″ board. The AD9000 is socketed to facilitate moderate volume testing. The evaluation board is offered with either a commercial temperature range AD9000, or an extended temperature range device installed.

The respective ordering numbers are AD9000JD/PCB and AD9000SD/PCB.

FUNCTIONAL BLOCK DIAGRAM

GENERAL DESCRIPTION

The AD9002 is an 8-bit, high speed, analog-to-digital converter. The AD9002 is fabricated in an advanced bipolar process which allows operation at sampling rates in excess of 150 megasamples/second. Functionally, the AD9002 is comprised of 256 parallel comparator stages whose outputs are decoded to drive the ECL compatible output latches.

An exceptionally wide large signal analog input bandwidth of 160MHz is due to an innovative comparator design and very close attention to device layout considerations. The wide input bandwidth of the AD9002 allows very accurate acquisition of high speed pulse inputs, without an external track-and-hold. The comparator output decoding scheme minimizes false codes which is critical to high speed linearity.

The AD9002 provides an external hysteresis control pin which can be used to optimize comparator sensitivity to further improve performance. Additionally, the AD9002's low power dissipation of 750mW makes it usable over the full extended temperature range. The AD9002 also incorporates an overflow bit to indicate overrange inputs. This overflow output can be disabled with the overflow inhibit pin.

The AD9002 is available in two grades, one with 0.5LSB linearity and one with 0.75LSB linearity. Both versions are offered in an industrial grade, −25°C to +85°C, packaged in a 28-pin DIP and a 28-pin PLCC. The military temperature range devices, −55°C to +125°C, are available in ceramic DIP and LCC packages and are compliant to MIL-STD-883 Class B.

NOTES

[1]Absolute maximum ratings are limiting values, to be applied individually, and beyond which the serviceability of the circuit may be impaired. Functional operability under any of these conditions is not necessarily implied. Exposure to absolute maximum rating conditions for extended periods of time may affect device reliability.

[2]$+V_{REF} \geq -V_{REF}$ under all circumstances.

[3]Maximum junction temperature (t_J max) should not exceed 175°C for ceramic packages, and 150°C for plastic packages:

$t_J = PD\ (\theta_{JA}) + t_A$

$PD\ (\theta_{JC}) + t_C$

where

PD = power dissipation

θ_{JA} = thermal impedance from junction to ambient (°C/W)

θ_{JC} = thermal impedance from junction to case (°C/W)

t_A = ambient temperature (°C)

t_C = case temperature (°C)

typical thermal impedances are:

Ceramic DIP $\theta_{JA} = 56°C/W$; $\theta_{JC} = 20°C/W$

Plastic DIP $\theta_{JA} = 60°C/W$; $\theta_{JC} = 20°C/W$

Ceramic LCC $\theta_{JA} = 69°C/W$; $\theta_{JC} = 23°C/W$

PLCC $\theta_{JA} = 60°C/W$, $\theta_{JC} = 19°C/W$.

[4]Measured with AIN = 0V.

[5]Measured by FFT analysis where fundamental is −3dBc.

[6]Input slew rate derived from rise time (10 to 90%) of full scale input.

[7]Outputs terminated through 100Ω to −2V.

[8]Measured from ENCODE in to data out for LSB only.

[9]For full-scale step input, 8-bit accuracy is attained in specified time.

[10]Recovers to 8-bit accuracy in specified time after 150% full-scale input overvoltage.

[11]Output time skew includes high-to-low and low-to-high transitions as well as bit-to-bit time skew differences.

[12]ENCODE signal rise/fall times should be less than 10ns for normal operation.

[13]Measured at 125MSPS encode rate.

[14]Analog input frequency = 1.23MHz.

[15]RMS signal to rms noise, with 1.23MHz analog input signal.

[16]Input signals 1V p-p @1.23MHz and 1V p-p @2.30MHz.

[17]Supplies should remain stable within ±5% for normal operation.

[18]Measured at −5.2V ±5%.

Specifications subject to change without notice.

2

Recommended Operating Conditions

Parameter	Input Voltage Min	Nominal	Max
$-V_S$	−5.46	−5.20	−4.94
$+V_{REF}$	$-V_{REF}$	0.0V	+0.1
$-V_{REF}$	−2.1	−2.0	$+V_{REF}$
Analog Input	$-V_{REF}$		$+V_{REF}$

EXPLANATION OF TEST LEVELS

Test Level I – 100% production tested.

Test Level II – 100% production tested at +25°C, and sample tested at specified temperatures.

Test Level III – Sample tested only.

Test Level IV – Parameter is guaranteed by design and characterization testing.

Test Level V – Parameter is a typical value only.

Test Level VI – All devices are 100% production tested at +25°C. 100% production tested at temperature extremes for extended temperature devices; sample tested at temperature extremes for commercial/industrial devices.

ORDERING GUIDE

Model	Linearity	Temperature Range	Package Option[1]
AD9002AD	0.75LSB	−25°C to +85°C	D-28
AD9002BD	0.50LSB	−25°C to +85°C	D-28

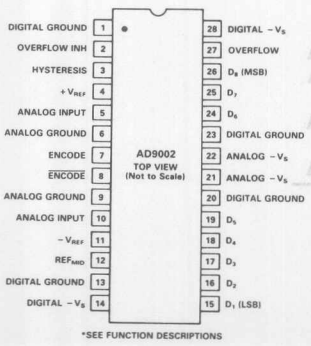
FUNCTIONAL DESCRIPTION



Pin #	Name	Description
1	DIGITAL GROUND	One of four digital ground pins. All digital ground pins should be connected together.
2	OVERFLOW INH	OVERFLOW INHIBIT controls the data output polarity for overvoltage inputs.

ANALOG INPUT	OVERFLOW ENABLED (FLOATING OR −5.2V) OF D_1 D_2 D_3 D_4 D_5 D_6 D_7 D_8	OVERFLOW INHIBITED (GND) OF D_1 D_2 D_3 D_4 D_5 D_6 D_7 D_8
$V_{IN} > +V_{REF}$	1 0 0 0 0 0 0 0 0	0 1 1 1 1 1 1 1 1
$V_{IN} \leq +V_{REF}$	0 X X X X X X X X	0 X X X X X X X X

3	HYSTERESIS	The Hysteresis control voltage varies the comparator hysteresis from 0mV to 10mV, for a change from −5.2V to −2.2V at the Hysteresis control pin.
4	$+V_{REF}$	The most positive reference voltage for the internal resistor ladder.
5	ANALOG INPUT	One of two analog input pins. Both analog input pins should be connected together.
6	ANALOG GROUND	One of two analog ground pins. Both analog ground pins should be connected together.
7	ENCODE	Noninverted input of the differential encode input. This pin is driven in conjunction with $\overline{\text{ENCODE}}$. Data is latched on the rising edge of the ENCODE signal.
8	$\overline{\text{ENCODE}}$.	Inverted input of the differential encode input. This pin is driven in conjunction with ENCODE.
9	ANALOG GROUND	One of two analog ground pins. Both analog ground pins should be connected together.
10	ANALOG INPUT	One of two analog input pins. Both analog inputs should be connected together.
11	$-V_{REF}$	The most negative reference voltage for the internal resistor ladder.
12	REF_{MID}	The midpoint tap on the internal resistor ladder.
13	DIGITAL GROUND	One of four digital ground pins. All digital ground pins should be connected together.
14	DIGITAL $-V_S$	One of two negative digital supply pins (nominally −5.2V). Both digital supply pins should be connected together.
15	D1	Digital data output (LSB).
16-19	D2-D5	Digital data output.
20	DIGITAL GROUND	One of four digital ground pins. All digital ground pins should be connected together.
21, 22	ANALOG $-V_S$	One of two negative analog supply pins (nominally −5.2V). Both analog supply pins should be connected together.
23	DIGITAL GROUND	One of four digital ground pins. All digital ground pins should be connected together.
24, 25	D6, D7	Digital data output.
26	D8	Digital data output (MSB).
27	OVERFLOW	Overflow data output. Logic high indicates an input overvoltage ($V_{IN} > +V_{REF}$) if OVERFLOW INHIBIT is enabled (overflow enabled, −5.2V). See OVERFLOW INHIBIT.
28	DIGITAL $-V_S$	One of two negative digital supply pins (nominally −5.2V). Both digital supply pins should be connected together.

Bond Wire	1–1.3 mil Gold; Gold Ball Bonding

APPLICATION INFORMATION

The AD9002 is compatible with all standard ECL logic families, including 10K and 10KH. 100K ECL's logic levels are temperature compensated, and are therefore compatible with the AD9002 (and most other ECL device families) only over a limited temperature range. To operate at the highest encode rates, the supporting logic around the AD9002 will need to be equally fast. Whichever of the ECL logic families is used, special care must be exercised to keep digital switching noise away from the analog circuits around the AD9002. The two most critical items are digital supply lines and digital ground return.

The input capacitance of the AD9002 is an exceptionally low 17pF. This allows the use of a wide range of input amplifiers, both hybrid and monolithic. To take full advantage of the wide input bandwidth of the AD9002, a hybrid amplifier such as the AD9610 will be required. For those applications that do not require the full input bandwidth of the AD9002, more traditional monolithic amplifiers, such as the AD846, will work very well. Overall performance with any amplifier can be improved by inserting a 10Ω resistor in series with the amplifier output.

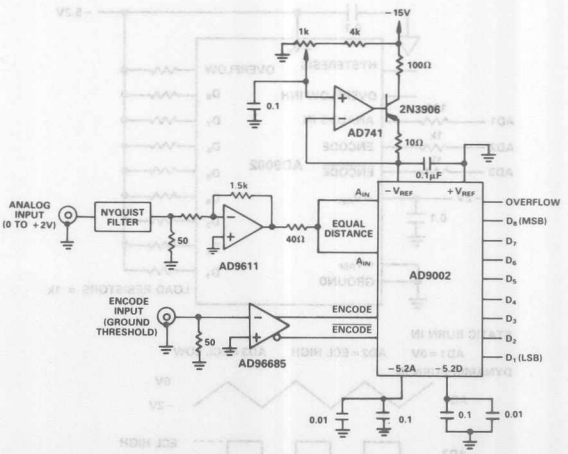
The output data is buffered through the ECL compatible output latches. All data is delayed by one clock cycle, in addition to the latch propagation delay (t_{PD}), before becoming available at the outputs. Both the analog-to-digital conversion cycle and the data transfer to the output latches are triggered on the rising edge of the differential, ECL compatible ENCODE signal (see timing diagram). In applications where only a single-ended signal is available, the AD96685, a high speed, ECL voltage comparator, can be employed to generate the differential signals. All ECL signals (including the overflow bit) should be terminated properly to avoid ringing and reflection.

The AD9002 also incorporates a HYSTERESIS control pin which provides from 0 to 10mV of additional hysteresis in the comparator input stages. Adjustments in the HYSTERESIS control voltage may help improve noise immunity and overall performance in harsh environments.

The OVERFLOW INHIBIT pin of the AD9002 determines how the converter handles overrange inputs ($AIN \geq +V_{REF}$). In the "enabled" state (floating at $-5.2V$), the OVERFLOW output will be at logic HIGH and all other outputs will be at logic LOW for overrange inputs (return-to-zero operation). In the "inhibited" state (tied to ground), the OVERFLOW output will be at logic LOW, and all other outputs will be at logic HIGH for overrange inputs (nonreturn-to-zero operation).

The AD9002 provides outstanding error rate performance. This is due to tight control of comparator offset matching and a fault tolerant decoding stage. Additional improvements in error rate are possible through the addition of hysteresis (see HYSTERESIS control pin). This level of performance is extremely important in fault-sensitive applications such as digital radio (QAM).

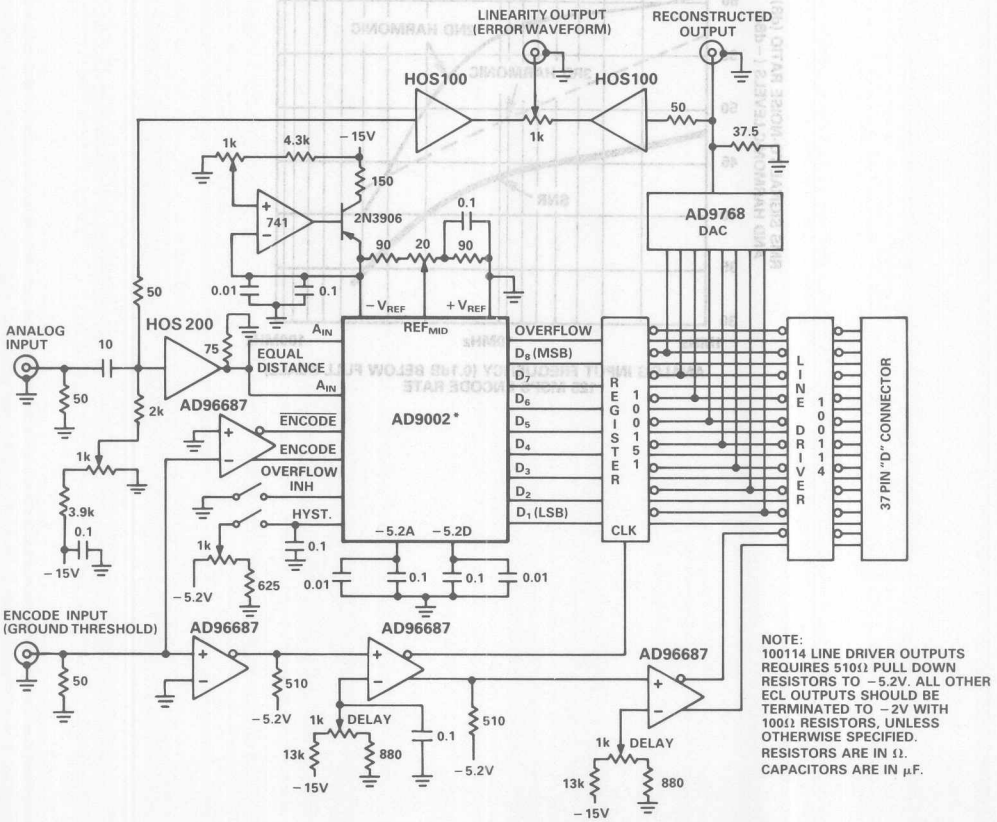
Dramatic improvements in comparator design and construction give the AD9002 excellent dynamic characteristics, especially SNR (signal-to-noise ratio). The 160MHz input bandwidth and low error rate performance give the AD9002 an SNR of 48dB with a 1.23MHz input. High SNR performance is particularly important in wide bandwidth applications, such as pulse signature analysis, commonly performed in advanced radar receivers.



LAYOUT SUGGESTIONS

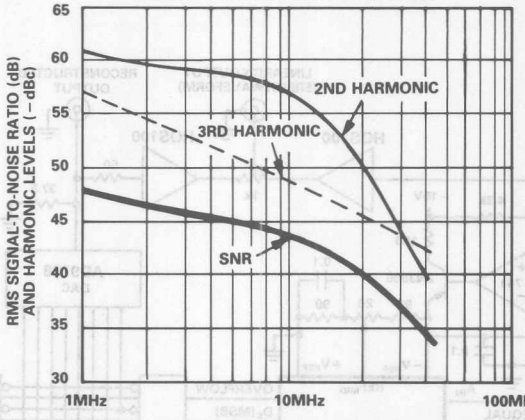
Designs using the AD9002, like all high speed devices, must follow a few basic layout rules to insure optimum performance. Essentially, these guidelines are meant to avoid many of the problems associated with high speed designs. The first requirement is for a substantial ground plane around and under the AD9002. Separate ground plane areas for the digital and analog components may be useful, but these separate grounds should be connected together at the AD9002 to avoid the effects of "ground loop" currents.

The second area that requires an extra degree of attention involves the three reference inputs, $+V_{REF}$, REF_{MID}, and $-V_{REF}$. The $+V_{REF}$ input and the $-V_{REF}$ input should both be driven from a low impedance source (note that the $+V_{REF}$ input is typically tied to analog ground). A low drift amplifier should provide satisfactory results, even over an extended temperature range. Adjustments at the REF_{MID} input may be useful in improving the integral linearity by correcting any reference ladder skews. The application circuit shown below demonstrates a simple and effective means of driving the reference circuit.



The reference inputs should be adequately decoupled to ground through 0.1μF chip capacitors to limit the effects of system noise on conversion accuracy. The power supply pins must also be decoupled to ground to improve noise immunity; 0.1μF and 0.01μF chip capacitors are recommended.

The analog input signal is brought into the AD9002 through two separate input pins. It is very important that the two input pins be driven symmetrically with equal length electrical connections. Otherwise, aperture delay errors may degrade converter performance at high frequencies.



Typical AD9002 Application

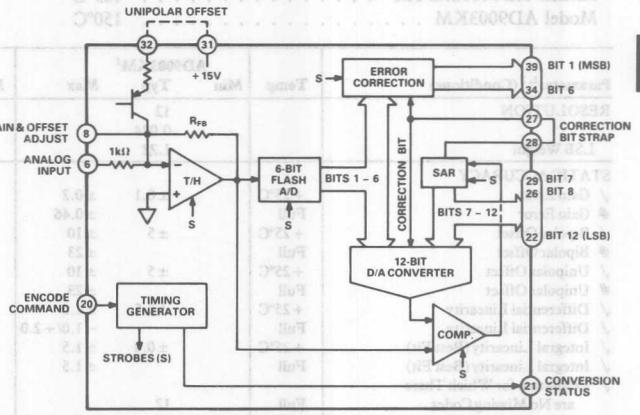
AD9002 DYNAMIC PERFORMANCE



12-Bit, 1 MSPS A/D Converter

AD9003

FEATURES
- 12-Bit Resolution
- 1 MSPS Word Rates
- T/H and Timing Included
- Single 40-Pin DIP

APPLICATIONS
- Radar Systems
- Digital Oscilloscopes
- Test Systems
- Analytical Instrumentation
- Waveform Analyzers

FUNCTIONAL BLOCK DIAGRAM

GENERAL DESCRIPTION

The AD9003 is a complete 12-bit, 1 MSPS analog-to-digital converter (ADC) which combines low cost and high performance in a single 40-pin DIP. This unique converter includes track-and-hold (T/H), timing, and encoding functions with a power dissipation of only 2.2 watts.

This remarkable unit is capable of converting analog signals to the Nyquist limit at word rates through 1 MSPS. Its 1μs conversion interval includes acquisition time for the internal T/H, making it a true 1 MSPS converter.

Proprietary conversion techniques achieve linearity equivalent to the best successive approximation ADC along with subranging conversion speeds. A conversion status signal simplifies transferring output data into system logic. Innovative thick- and thin-film technologies assure excellent performance over temperature without compromising ac characteristics.

The AD9003KM operates at case temperatures from 0 to +70°C; the SM and TM units operate from −25°C to +100°C.

NOTES

✓ 100% tested (See Notes 1 and 2). #Specification guaranteed by design; not tested.

[1]AD9003KM parameters preceded by a check (✓) are tested at +25°C ambient temperature; performance is guaranteed over the commercial temperature range (0 to +70°C case temperature).

[2]AD9003SM and TM parameters preceded by a check (✓) are tested at −25°C case, +25°C ambient, and +100°C case temperatures.

[3]Converting in excess of 1.0MHz is possible; however, acquisition time is reduced, which may increase distortion of high-frequency analog signals.

[4]In-band harmonics are expressed in dB below FS in terms of spurious in-band signals generated at 1MHz encode rate and single tone analog input in range shown.

[5]Measured from leading edge of encode command to trailing (rising) edge of conversion status signal (see Timing Diagram).

[6]RMS signal to rms noise ratio; analog input 1dB below FS @ 100kHz; 1MHz encode rate.

[7]For full-scale step input, 12-bit accuracy attained in specified time.

[8]Recovers to 12-bit accuracy in specified time after 2 × FS input overvoltage. (See text and Figure 5 for information on overloads.)

[9]Intermodulation measured in dB below FS at 1MHz encode rate with input frequencies of 75kHz and 105kHz; each 7dB below FS.

[10]Voltage Range = ±2.5V or 0V to −5.0V.

[11]With analog input 40dB below FS.

[12]With FS analog input. (Large-signal BW flat within 0.5dB, dc to 500kHz.)

[13]Transition from "0" to "1" initiates conversion.

[14]For 1MHz encode rate. At conversions below 1MHz, max width is conversion period minus 250ns. Optimum linearity at 200 to 250ns widths.

[15]Power Supply Rejection Ratio (PSRR) is sensitivity of offset to V_{CC}. This is parameter which is most sensitive to variations in supply voltage.

[16]The relationship between the device package and outside environment (θ_{ca}) varies with the application. Value shown is based on measuring case temperature with supply voltages applied to a device installed in a ZIF socket mounted on a standard "EJ" burn-in board.

[17]Calculated for SM/TM versions using MIL-HNBK-217; Ground Fixed; +80°C case temperature.

[18]M = Metal Can DIP. For outline information see Package Information section.

ORDERING INFORMATION

For operating case temperatures from 0 to +70°C, order part number AD9003KM. Two models are available for operation at case temperatures betweeen −25°C and +100°C. With the exception of differential linearity, the electrical specifications on these devices are the same. The AD9003SM guarantees no missing codes over temperature; the AD9003TM is screened for differential nonlinearity of ±1LSB maximum.

Both the commercial temperature and extended temperature versions are packaged in 40-pin metal can DIPs.

PIN	FUNCTION	PIN	FUNCTION

NOTES
Although Grounds are Designated as Analog or Digital, All Grounds Should Be Connected to a Single Common Low-Impedance Ground Plane for Best Results.

[1]Pins 2 and 31 Must Be Bypassed to Ground with 0.1μF for Optimum Performance.
[2]For Unipolar Operation, Connect Pins 31 and 32; for Bipolar Operation, Ground Pin 32 and Connect Pin 31 Only to 0.1μF.
[3]Pins 27 and 28 Must Always Be Strapped Together with No Other Connections.

THEORY OF OPERATION

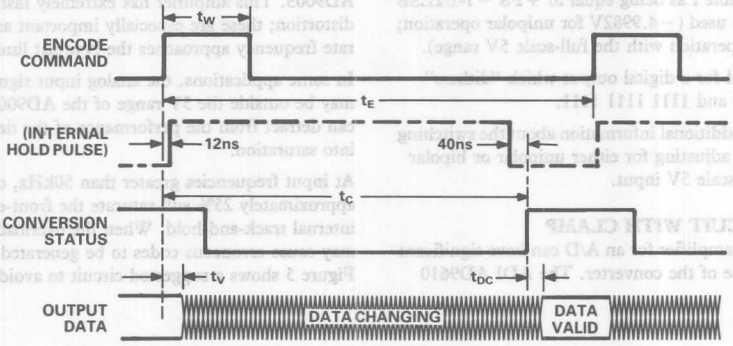
Refer to the block diagram of the AD9003.

Basically, the design of the unit is based on successive approximation techniques. However, the AD9003 also uses parallel encoding for the most significant bits (MSBs).

When a TTL-compatible Encode Command signal is applied to Pin 20, it causes the internal Timing Generator to generate strobe pulses used for controlling the timing of the various actions within the device.

The encode command causes the track-and-hold (T/H) to switch from a "track" mode to a "hold" mode; switches the 6-bit flash converter to a tracking mode of operation to allow it to reach the held value from the T/H; and resets the SAR. When the flash converter output has been determined, Bits 1 – 6 become inputs to the 12-bit D/A converter.

If the D/A voltage applied to the comparator is greater than the "held" value being applied to the comparator, a correction bit is turned on. If the D/A voltage is less, there is no correction bit and no change in the signal.



At this point, the D/A output voltage and the correction circuit outputs are 12-bit accurate. Standard successive approximation techniques are used to determine Bits 7 – 12; the end result is a 12-bit parallel output from the AD9003 A/D Converter.

The overall linearity of the AD9003 is independent of the flash converter, which materially enhances the performance of the unit. In addition, the architecture used in the converter makes it less sensitive to nonlinearities caused by D/A and/or comparator settling.

Performance of the AD9003 is equivalent to that of an ultrahigh-speed SAR type of design. But the design techniques which are used relieve the stringent comparator/DAC settling requirements usually associated with SAR designs. Instead, the AD9003 reaps the benefits of combining the best characteristics of flash converters and SARs while avoiding the penalties which are inherent in each individually.

Refer to Figure 1, the timing diagram for the AD9003. In this illustration, spacing between encode commands is shown as it would be for a 1MHz word rate, i.e., 1000ns. The width of the encode pulse is at its minimum value of 200ns.

The period of data validity associated with each encode command appears, in the figure, to be relatively short. Remember, however, each encode command generates the necessary switching to perform the digitizing function, and causes the output data to begin changing.

		MIN	MAX
t_W	ENCODE COMMAND PULSE WIDTH	200ns	750ns
t_E	SPACING BETWEEN ENCODE COMMANDS	1000ns	
t_C	CONVERSION TIME		850ns
t_V	DATA VALID		50ns
t_{DC}	DATA CHANGING		35ns

Figure 1. AD9003 Timing Diagram

In Figure 1, the timing is based on a maximum encode rate, with minimum spacing between encode commands. At lower conversion rates, this spacing would be lengthened correspondingly and the interval when data are valid would become longer.

Internal timing within the AD9003 typically requires 770ns to accomplish the necessary switching and processing of the analog input "frozen" by the encode command. Since the AD9003 is a true 1MHz converter, this leaves 230ns for the T/H to re-establish full accuracy when it returns to the "track" mode at the completion of the digitizing period.

This addition of the required 770ns and the 230ns accuracy increment shows up as a total of 1,000ns minimum between encode commands in Figure 1; any shorter interval will detract from the overall performance of the unit. Higher encode rates, i.e., shorter intervals between encode commands, are possible; but they may cause distortion on high-frequency analog signals because the T/H will not be fully settled when it is switched to the "hold" mode.

SETTING GAIN AND OFFSET

Varying gain and offset for the AD9003 enhances performance of the unit and increases its flexibility in applications. One suggested method of obtaining approximately 5% variation in each is shown in Figure 2.

The AD9003 can be operated in a unipolar mode or a bipolar mode; strap options and adjustments of the external controls shown in Figure 2 determine which is used. When calibrating for either mode, apply an encode command at the word rate frequency of the system to Pin 20.

Connect a precision voltage source between the ANALOG INPUT connection shown in Figure 2 and ground. Set its output for the voltage shown in Table I as being equal to −FS + 1/2LSB for the input range to be used (−0.6mV for unipolar operation and +2.4994V for bipolar operation if using the full-scale 5V input range of the AD9003).

Adjust the OFFSET control for a digital output which "dithers" between 0000 0000 0000 and 0000 0000 0001.

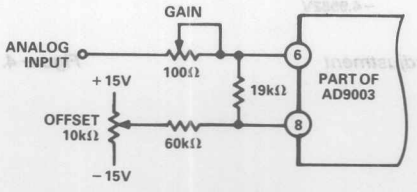


Figure 2. AD9003 Gain and Offset

To set gain, readjust the output of the voltage reference source to the value shown in Table I as being equal to +FS −1-1/2LSB for the input range to be used (−4.9982V for unipolar operation; −2.4982V for bipolar operation with the full-scale 5V range).

Adjust the GAIN control for a digital output which "dithers" between 1111 1111 1110 and 1111 1111 1111.

Figures 3 and 4 provide additional information about the switching points of the LSB when adjusting for either unipolar or bipolar operation using the full-scale 5V input.

AD9003 DRIVER CIRCUIT WITH CLAMP

The choice of the driver amplifier for an A/D can have significant effect on the performance of the converter. The ADI AD9610 Op Amp is the recommended choice for operation with the AD9003. This amplifier has extremely fast settling time and low distortion; these are especially important as the selected word rate frequency approaches the Nyquist limit.

In some applications, the analog input signals to be digitized may be outside the 5V range of the AD9003 converter, which can detract from the performance of the device by driving it into saturation.

At input frequencies greater than 50kHz, overloads larger than approximately 25% will saturate the front-end circuits of the internal track-and-hold. When the overload is removed, the T/H may cause erroneous codes to be generated at the output. Figure 5 shows a suggested circuit to avoid this.

Table I.

For UNIPOLAR Input	Apply Reference	And Adjust	For "Dither" Between	For BIPOLAR Input	Apply Reference	And Adjust	For "Dither" Between
0 to −5V	−0.6mV	OFFSET	0000 0000 0000 and 0000 0000 0001	0.00	0.00	OFFSET	0111 1111 1111 and 1000 0000 0000
0 to −5V	−4.9982V	GAIN	1111 1111 1110 and 1111 1111 1111	±2.5V	−2.4982V	GAIN	1111 1111 1110 and 1111 1111 1111

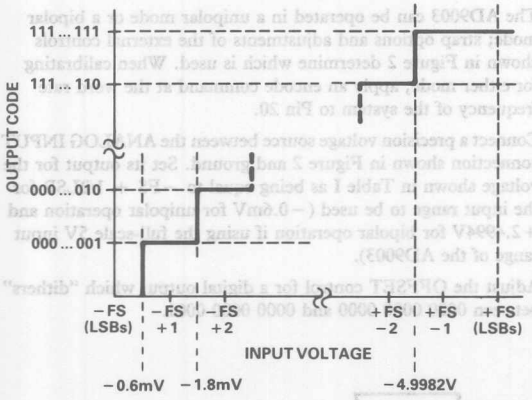

Figure 3. AD9003 Unipolar Adjustment

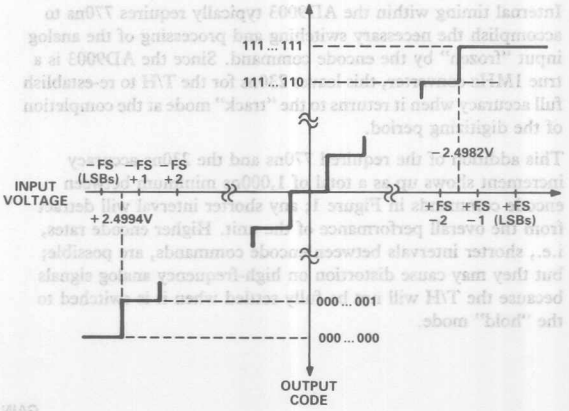

Figure 4. AD9003 Bipolar Adjustment

In this diagram, the value of the feed forward resistor R_{FF} is calculated on the basis of the equation:

$$R_{FF} = |\text{Desired Full-Scale Bipolar Voltage}| \times 500$$

The circuit eliminates saturating the internal T/H of the AD9003. Using an Analog Devices AD9610 ahead of the converter allows ±3x overdrives before the amplifier goes into saturation. Even in those instances in which the input signal exceeds the ±3x limit, the AD9610 comes out of saturation much more quickly than the input circuits of the converter would under the same circumstances.

Bipolar inputs to the AD9003 are held to a maximum of ±2.5V by the clamp circuits made up of 1N2810 Schottky diodes. The Analog Devices AD744 amplifiers and their associated circuits are for the purpose of clamping the Schottky diodes at the desired maximum input levels. As shown, +CLAMP ADJUST and −CLAMP ADJUST are set for +2.530V and −2.530V respectively.

These adjustment values take into account the gain and offset tolerances of the AD9003. If resistors with low temperature coefficients are selected, the clamp circuit will operate over the entire temperature range of the converter.

The bipolar circuit in Figure 5 can also be used for unipolar operation of the A/D with only minor changes. For this mode, the upper op amp (AD744 #1) and its associated reference circuits are removed; the upper 1N2810 clamp is connected, instead, to ground.

With these changes, the unipolar full-scale overdrive limit is 1.5x rather than the 3x of the bipolar connections; but this will prevent saturating the front end circuits of the AD9003. The value of R_{FF} in the unipolar circuit is based on:

$$R_{FF} = |\text{Desired Full-Scale Unipolar Voltage}| \times 250$$

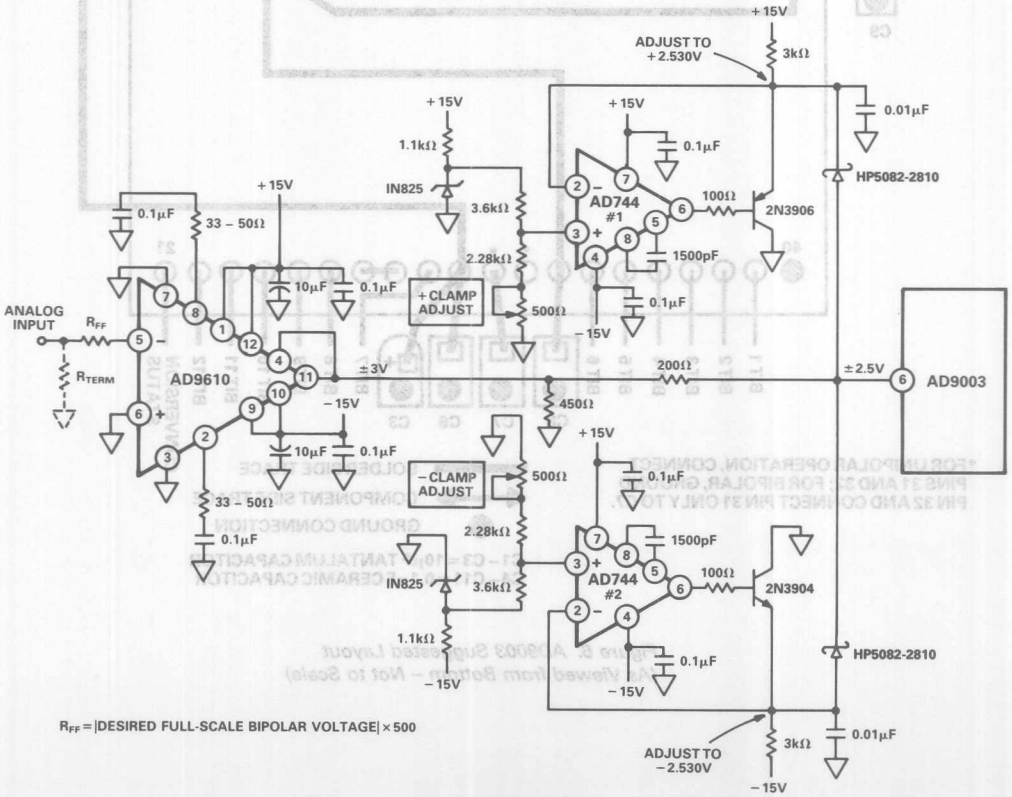

Figure 5. AD9003 Driver Circuit with Clamp

in laying out the circuit. It is critical to use the shortest possible lead lengths and circuit runs. Construct the circuit on a large, low-impedance ground plane containing the maximum possible power supplies; these should be connected as closely as possible to the supply pins. A suggested layout for the AD9003 when it is mounted on a printed circuit board is shown in Figure 6.

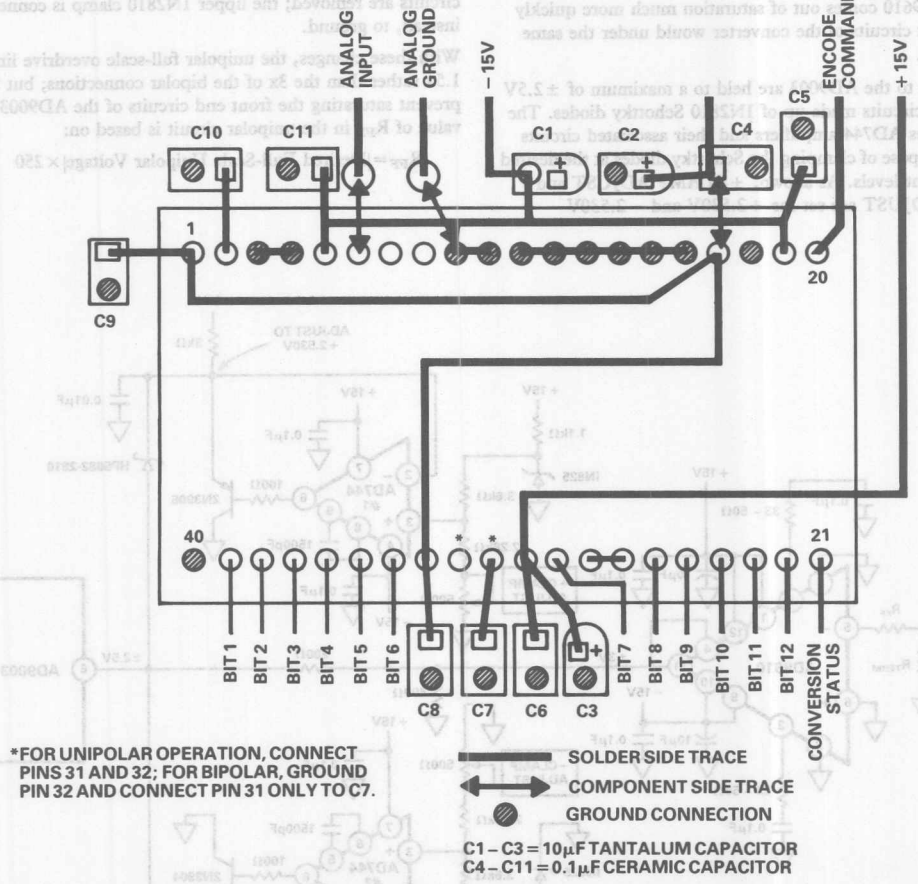

Figure 6. AD9003 Suggested Layout (As Viewed from Bottom – Not to Scale)

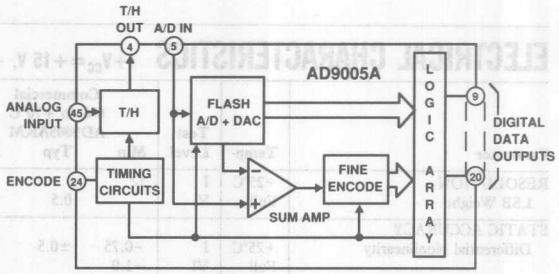
12-Bit, 10 MSPS A/D Converter

AD9005A



FEATURES

- Complete 12-Bit A/D Converter
- Includes Track and Hold, Reference, and Timing
- Bipolar Analog Input (±1.024 V)
- Up to 10 MSPS Sampling Rate
- Low Power Dissipation: 3.2 W
- Low Harmonic Distortion
- MIL-STD-883-Compliant Versions Available

APPLICATIONS

- Radar
- Digital Receivers
- Electro-Optics
- Medical Scanners
- Signal Intelligence
- Spectrum Analyzers

FUNCTIONAL BLOCK DIAGRAM

GENERAL DESCRIPTION

The AD9005A is a complete 12-bit A/D converter which includes on-board track-and-hold amplifier, voltage reference, and timing circuits. Featuring sampling rates from dc to 10 MSPS, the AD9005A uses a subranging converter architecture to achieve high speed and high resolution. Dynamic performance includes a SNR of 64 dB and harmonic distortion of −72 dBc with a 4.3 MHz analog input.

This unit replaces its predecessor, the AD9005. The AD9005A uses a higher level of integration than the earlier design to provide increased performance, better reliability, and reduced cost.

The AD9005ALM guarantees a minimum 76 dBc (@ 2.3 MHz) spurious free dynamic range (SFDR) for applications which have demanding ac performance requirements. All grades are fully tested for dynamic performance.

Critical to the performance of the AD9005A is the use of advanced bipolar integrated circuits, custom designed for this device and manufactured by Analog Devices. The AD9005A is TTL-compatible with offset binary outputs. It is available in a 46-pin hermetic metal DIP in two temperature ranges: 0°C to +70°C commercial range and −55°C to +125°C military range (case temperature).

The AD9005A is available in versions compliant with MIL-STD-883. Refer to the *Analog Devices Military Products Databook* or current AD9005A/883B data sheet for detailed specifications.

AD9005A—SPECIFICATIONS

ABSOLUTE MAXIMUM RATINGS[1]

Positive Supply Voltage ($+V_{CC}$) . . . . . +18 V
Negative Supply Voltage ($-V_{EE}$) . . . . . −18 V
Positive Supply Voltage ($+V_S$) . . . . . +6 V
Negative Supply Voltage ($-V_S$) . . . . . −6 V
Analog Input Voltage (Pin 45) . . . . . ±3.0 V dc
Digital Input Voltage . . . . . −0.5 V to $+V_S$
Digital Output Current . . . . . 4 mA

Operating Temperature Range (Case)
AD9005KM . . . . . 0°C to +70°C

NOTES

[1]Absolute maximum ratings are limiting values, to be applied individually, and beyond which the serviceability of the circuit may be impaired. Functional operation under any of these conditions is not necessarily implied. Exposure to absolute rating conditions for extended periods of time may affect device reliability.

[2]Maximum junction temperature should not be allowed to exceed +175°C. Hybrid thermal model:

$t_{JUNCTION} = t_{AMBIENT} + P_{DISSIPATION} \times (\theta_{CA}) + (T_S - T_C)$ max

where $(T_S - T_C)$ max = 10°C

46 Pin metal DIP: θ_{CA} = 14°C/W in still air;

θ_{CA} = 6°C/W with 500 LFPM air flow

[3]Determined by 3 dB reduction in reconstructed output.

[4]Input at 1 dB below full scale.

[5]Measured at 10 MHz encode rate.

[6]Measured from ENCODE in to data out for LSB only.

[7]For full-scale step input; 12-bit accuracy is attained in the specified time.

[8]Recovers to 12-bit accuracy in specified time following 200% full-scale input voltage.

[9]Excludes pipeline delay of two clock cycles (see timing diagram).

[10]Worst case spurious in-band signal relative to input level.

[11]RMS signal to RMS noise, including harmonics.

[12]Worst case spurious in-band signal relative to level of input tones, which are both −7 dB below full scale.

[13]Sensitivity of full-scale gain error with respect to power supply variation within supply Min/Max limits.

[14]ENCODE signal rise and fall times should be less than 5 ns for normal operation. Transition from "0" to "1" initiates conversion.

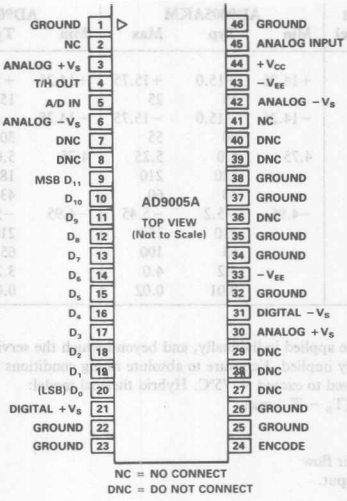
[15]PSRR is tested over given voltage range.

Specifications subject to change without notice.

EXPLANATION OF TEST LEVELS

Test Level

I – 100% production tested.



II – 100% production tested at +25°C, and sample tested at specified temperatures.

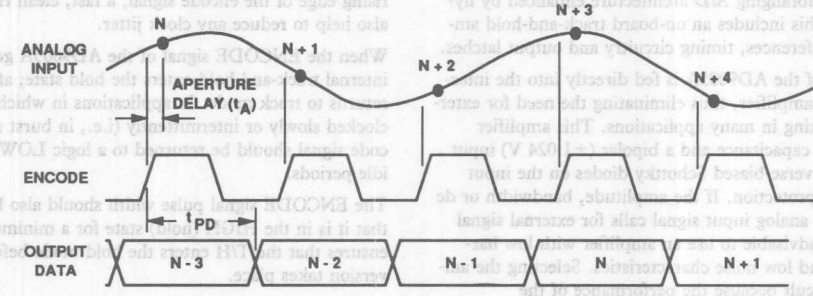
III – Periodically sample tested only.

IV – Parameter is guaranteed by design and characterization testing.

V – Parameter is a typical value only.

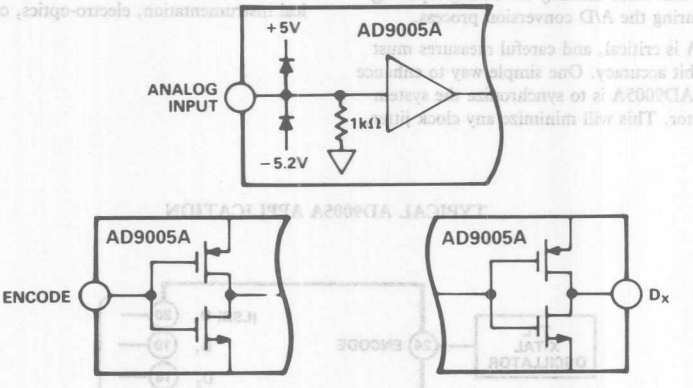
VI – All devices are 100% production tested at +25°C. 100% production tested at temperature extremes for military temperature devices. Guaranteed, not tested, for commercial temperature range

AD9005A PIN DESCRIPTIONS



Pin	Name	Description
1	GROUND	Circuit ground. All grounds should be connected together near the AD9005A.
2	NC	Not internally connected.
3	ANALOG $+V_S$	Positive analog supply pin. Nominally +5 V dc.
4	T/H OUT	Output of internal track-and-hold amplifier. Connect to Pin 5 for normal operation.
5	A/D IN	Input to internal A/D encoder. Connect to Pin 4 for normal operation.
6	ANALOG $-V_S$	Negative analog supply pin. Nominally −5.2 V dc.
7, 8	DNC	Do not connect. Internal test point.
9	D_{11} (MSB)	Most significant bit of digital output data.
10–19	D_1–D_{10}	Digital data outputs.
20	D_0 (LSB)	Least significant bit of digital output data.

OUTPUT CODING



ANALOG INPUT	D_{11}	D_{10}	D_9	D_8	D_7	D_6	D_5	D_4	D_3	D_2	D_1	D_0
≥+1.024V	1	1	1	1	1	1	1	1	1	1	1	1
≤−1.024V	0	0	0	0	0	0	0	0	0	0	0	0

21	DIGITAL $+V_S$	Positive digital supply pin. Nominally +5 V dc.
22, 23	GROUND	Circuit ground. All grounds should be connected together near the AD9005A.
24	ENCODE	Convert command. TTL compatible, rising edge triggered.
25, 26	GROUND	Circuit ground. All grounds should be connected together near the AD9005A.
27–29	DNC	Do not connect. Internal test point.
30	ANALOG $+V_S$	Positive analog supply pin. Nominally +5 V dc.
31	DIGITAL $-V_S$	Negative digital supply pin. Nominally −5.2 V dc.
32	GROUND	Circuit ground. All grounds should be connected together near the AD9005A.
33	$-V_{EE}$	Negative analog supply pin. Nominally −15 V dc.
34, 35	GROUND	Circuit ground. All grounds should be connected together near the AD9005A.
36	DNC	Do not connect. Internal test point.
37, 38	GROUND	Circuit ground. All grounds should be connected together near the AD9005A.
39, 40	DNC	Do not connect. Internal test point.
41	NC	Not internally connected.
42	ANALOG $-V_S$	Negative analog supply pin. Nominally −5.2 V dc.
43	$-V_{EE}$	Negative analog supply pin. Nominally −15 V dc.
44	$+V_{CC}$	Positive analog supply pin. Nominally +15 V dc.
45	ANALOG INPUT	Analog input. Full scale of ±1.024 V.
46	GROUND	Circuit ground. All grounds should be connected together near the AD9005A.

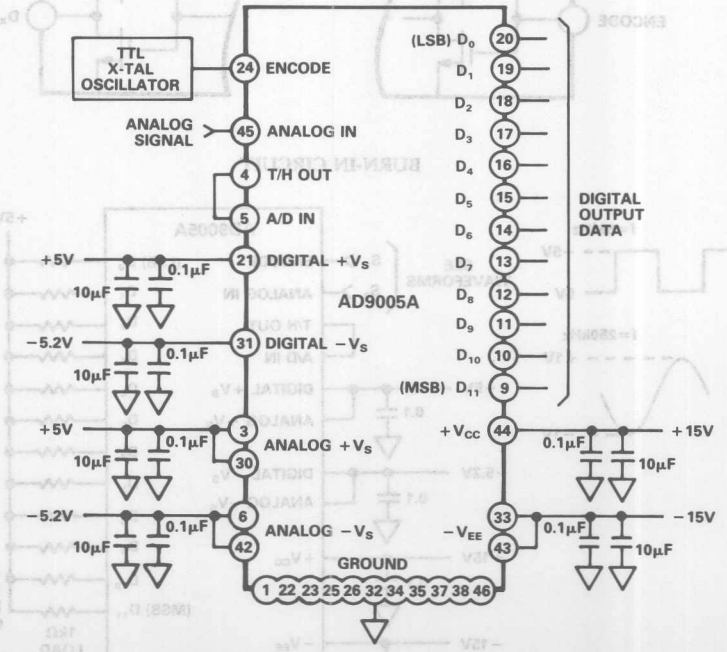
BURN-IN CIRCUIT

APPLICATIONS INFORMATION

The AD9005A is a complete analog-to-digital converter. The AD9005A uses a subranging A/D architecture enhanced by hybrid technology. This includes an on-board track-and-hold amplifier, on-board references, timing circuitry and output latches.

The analog input of the AD9005A is fed directly into the internal track-and-hold amplifier, thus eliminating the need for external signal conditioning in many applications. This amplifier provides low input capacitance and a bipolar (±1.024 V) input range. Normally reverse-biased Schottky diodes on the input provide overrange protection. If the amplitude, bandwidth or dc voltage level of the analog input signal calls for external signal conditioning, it is advisable to use an amplifier with low harmonic distortion and low noise characteristics. Selecting the amplifier may be difficult because the performance of the AD9005A will probably exceed the performance of most commercially available amplifiers. A notable exception is the AD9617, a wideband, low noise current feedback amplifier. It is important to remember that band limiting the analog input signal can avoid aliasing during the A/D conversion process.



Timing in the AD9005A is critical, and careful measures must be taken to support 12-bit accuracy. One simple way to enhance the performance of the AD9005A is to synchronize the system clock to a crystal oscillator. This will minimize any clock jitter, a must for maintaining the spectral purity of analog signals near Nyquist limits. Because the conversion cycle begins with the rising edge of the encode signal, a fast, clean rising edge will also help to reduce any clock jitter.

When the ENCODE signal of the AD9005A goes HIGH, the internal track-and-hold enters the hold state; after 65 ns, it returns to track mode. In applications in which the AD9005A is clocked slowly or intermittently (i.e., in burst mode), the encode signal should be returned to a logic LOW state during the idle periods.

The ENCODE signal pulse width should also be adjusted so that it is in the HIGH (hold) state for a minimum of 25 ns. This ensures that the T/H enters the hold mode before the A/D conversion takes place.

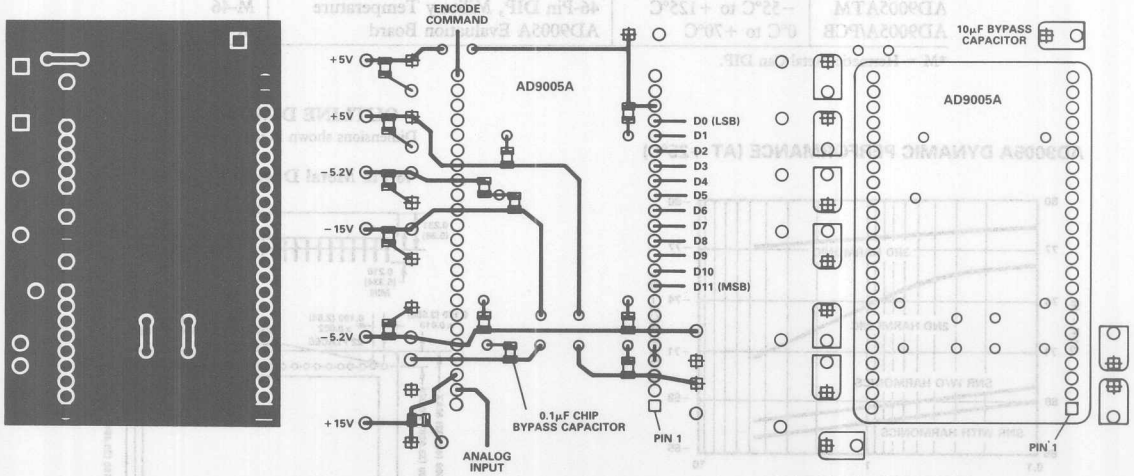
The AD9005A has many appealing characteristics for 12-bit A/D converter applications. Its dynamic performance is state-of-the-art in hybrid technology. Typical applications include radar, missile guidance, digital oscilloscopes, waveform analyzers, medical instrumentation, electro-optics, communications and ESM.

TYPICAL AD9005A APPLICATION

Layout Information

The accuracy of a 12-bit converter, especially one with the dynamic performance level of the AD9005A, requires that designers pay careful attention to printed circuit board layouts. Analog signal paths should be impedance matched, with termination/load resistors at or near package connections. Analog signal paths should also be isolated from digital signal paths. Otherwise digital signals can be capacitively coupled into the analog section of the circuit, degrading the overall performance of the A/D converter.

Digital switching noise on power supplies can also degrade converter performance. Because of this noise (inherent with TTL logic), the digital power supplies of the AD9005A should be separated from the analog power supplies. In addition, each power supply should be capacitively decoupled to ground. To accomplish this, a single large value capacitor with a high resonant frequency (a 10 μF tantalum capacitor for example) should be used on each of the AD9005A's power supplies, at or near the package. In addition, a lower value capacitor with good high frequency characteristics (a 0.1 μF ceramic chip capacitor is recommended) should be connected to each power supply pin connection.



For applications in which only single +5 V and/or −5.2 V supplies are available, a ferrite bead, placed in series between the analog and digital power pins, can be used to isolate the digital noise from the analog circuits.

Noise on the circuit ground is often the limiting factor in A/D converter performance. Perhaps the most critical concerns of circuit layout are the ground connections. To reduce ground noise, a two-sided printed circuit board is recommended, the component side being reserved (as much as possible) for a single, low impedance ground plane. The other side should be used for all (possible) power and signal connections. Each of the ground connections of the AD9005A should be connected to the ground plane, and most of the area under the AD9005A should be part of this ground plane. The metal case of the AD9005A is connected to ground.

Operation of the AD9005A requires that Pin 4, the output of the internal track-and-hold, be connected to Pin 5, the input to the AD9005A's A/D converter circuitry. A suggested layout, showing this connection, is shown below.

A final suggestion regarding circuit layout concerns the use of sockets. Ideally, parts should be soldered into boards in final designs. If sockets must be used, individual pin sockets are recommended to avoid lead inductance and capacitive coupling between adjacent pins. Pin sockets are available from Amp, part #6−330808−0.

OUTLINE DIMENSIONS

Dimensions shown in inches and (mm).

46-Pin Metal Dual In-Line Can

High Speed 6-Bit A/D Converters

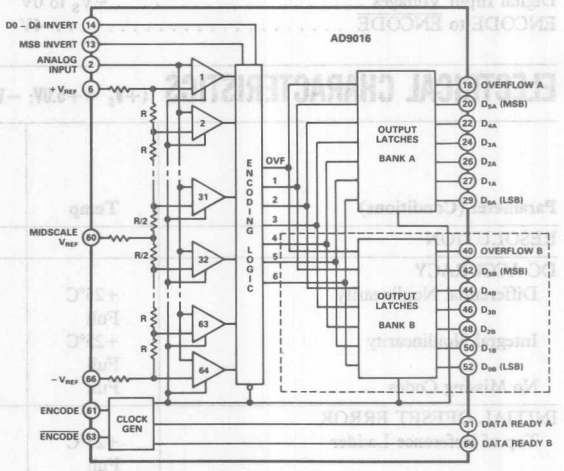
AD9006/AD9016

FEATURES

500MSPS Encode Rate
Very Low Input Capacitance: 8pF
30dB SNR @ 200MHz Analog Input
MIL-STD-883 Available
Bipolar Input Range (±1V)
Demultiplexed Outputs (AD9016)
MIL-STD-883-Compliant Versions Available

APPLICATIONS

Radar Warning Receivers
Electronic Countermeasures
Transient Recorders
"Smart" Munitions
Digital Oscilloscopes



GENERAL DESCRIPTION

The AD9006 and AD9016 are 6-bit, ultrahigh speed analog-to-digital converters. Both are fabricated in an advanced bipolar process, assuring exceptionally wide analog input bandwidth, and encode rates up to 500MSPS. Functionally, the AD9006 and AD9016 use "flash" architecture; the outputs of 64 parallel comparator stages are decoded to drive a bank of ECL output latches.

The AD9006 features a bipolar analog input range (±1V). Output data is provided in a single 6-bit data bank; the data is ECL compatible and also includes complementary Data Ready signals and an overflow bit. ECL-level control pins allow the user to invert the MSB and/or LSBs. The AD9006 exhibits excellent SNR performance (30dB SNR @ 200MHz input), and requires less than two watts of power.

In the AD9016, the performance and features of the AD9006 are combined with on-board demultiplexing circuits. Output data of the AD9016 are demultiplexed to two 6-bit data banks, each of which includes a Data Ready signal and overflow bit.

FUNCTIONAL BLOCK DIAGRAM

(Dotted Area Not Included in AD9006)

The AD9006 and AD9016 are available as commercial temperature range devices: 0 to +70°C; and military temperature range devices: −55°C to +125°C. Both versions are offered in a ceramic 68-pin LCC, and a ceramic 68-pin leaded package.

The AD9006/AD9016 are available in versions compliant with MIL-STD-883. Refer to the *Analog Devices Military Products Databook* or current AD9006/AD9016/883B data sheet for detailed specifications

$+V_S$ to Ground . . . . . −0.5V dc to +7.0V dc
AGND to DGND . . . . . −0.5V dc to +0.5V dc
$-V_S$ to Ground . . . . . +0.5V dc to −6.0V dc
ANALOG IN, $+V_{REF}$–V_{REF} . . . . . −1.5V to +1.5V
MIDSCALE V_{REF}[2]
$+V_{REF}$ to $-V_{REF}$ 2.1V

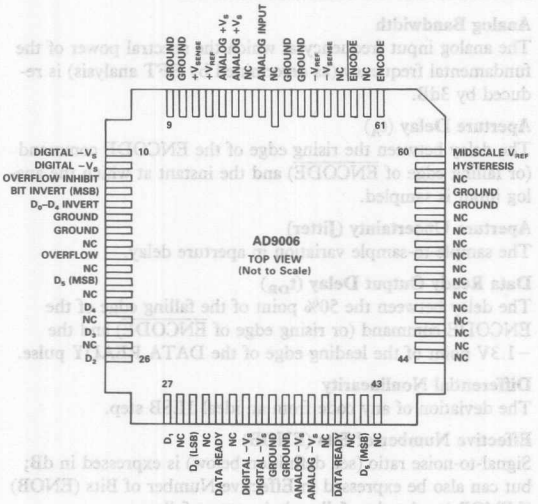
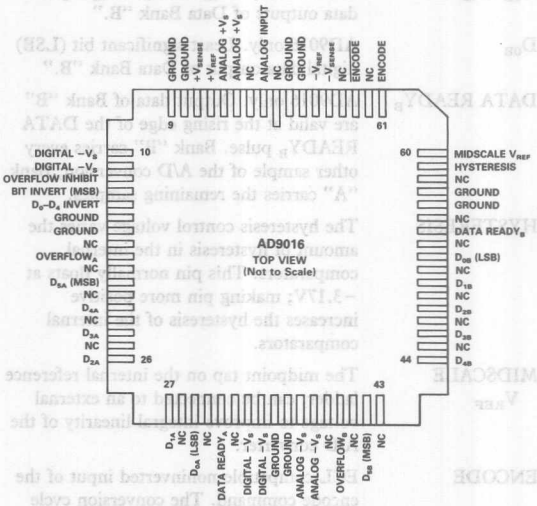
NOTES
[1]Absolute maximum ratings are limiting values, to be applied individually, and beyond which the serviceability of the circuit may be impaired. Functional operability is not necessarily implied. Exposure to absolute maximum rating conditions for an extended period of time may affect device reliability.
[2]$+V_{REF} > -V_{REF}$ under all circumstances.
[3]Typical thermal impedances:
68-pin leaded ceramic chip carrier θ_{JA} = 31°C/W; θ_{JC} = 1.1°C/W.
68-pin ceramic LCC θ_{JA} =36°C/W; θ_{JC} = 2.6°C/W.
[4]Measured with analog input =0V.
[5]Measured with use of Fast Fourier Transform (FFT). See Definitions.
[6]Outputs terminated through 100Ω to −2.0V; C_L<4pF
[7]Measured from 50% point of leading edge of ENCODE command to −1.3V point of output data.
[8]Output time skew includes HIGH-to-LOW and LOW-to-HIGH transitions as well as bit-to-bit time skew differences.
[9]Measured from 50% point of trailing edge of ENCODE command to 50% point of Data Ready pulse.
[10]For full scale step input, 6-bit accuracy is attained in the specified time.
[11]Recovers to 6-bit accuracy in specified time after 150% full scale input overvoltage.
[12]ENCODE command rise/fall times should be less than 2.5ns for normal operation.
[13]Measured at 400MSPS encode rate; input level 1.0dB below full scale (FS).
[14]RMS signal to rms noise with analog input signal of 1dB below full scale at specified frequency.
[15]Intermodulation measured with analog input frequencies of 60MHz and 70MHz at 7dB below full scale.
[16]Measured at $+V_S$ =+5.0V ±5% or $-V_S$ =−5.2V ±5%; specification shown is for worst case (see Definitions).
Specifications subject to change without notice.

EXPLANATION OF TEST LEVELS



Test Level

I – 100% production tested.
II – 100% production tested at +25°C, and sample tested at specified temperatures.
III – Sample tested only.
IV – Parameter is guaranteed by design and characterization testing.
V – Parameter is a typical value only.
VI – All devices are 100% production tested at +25°C. 100% production tested at temperature extremes for extended temperature devices; sample tested at temperature extremes for commercial/industrial devices.



ORDERING GUIDE

AD9006 Pin Designations

AD9016 Pin Designations

AD9006/AD9016 PIN DESCRIPTIONS

NC — Not internally connected.

ANALOG IN — Analog input connection. Analog input is nominally between −1.0V and +1.0V.

ANALOG $+V_S$ — Positive supply pins; nominally +5.0V.

$+V_{REF}$ — The positive reference voltage applied to the internal resistor ladder.

$+V_{SENSE}$ — Voltage sense line to the most positive reference voltage of the resistor ladder. The sense line is intended for connection to a high impedance node and has limited current capability. It is intended to be used to null offset at the top of the reference ladder.

GROUND — Analog and digital ground connections for the AD9006/AD9016 units. For optimum performance, all grounds should be connected together and to a low impedance ground plane as close to the device as possible. [NOTE: On both the AD9006 and the AD9016, Pins 8, 9, 15, 16, 35, 36, 56 and 57 are digital ground (DGND); pins 67 and 68 are analog ground (AGND).]

OVERFLOW INHIBIT — Overflow bit control pin. OVERFLOW INHIBIT is connected to ground for normal operation (no overflow bit, nonreturn-to- zero operation). When overflow inhibit is connected to −5.2V or allowed to float, OVERFLOW = HIGH and output bits = LOW when the analog input voltage exceeds $+V_{SENSE}$).

BIT INVERT (MSB) — Most significant bit (D_{05}) control pin. BIT INVERT (MSB) is connected to ground for normal operation. When connected to −5.2V or allowed to float, MSB output is inverted.

D_0–D_4 INVERT — Bits D_0–D_4 control pin, connected to ground for normal operation. When connected to −5.2V or allowed to float, D_0–D_4 data outputs are inverted.

$OVERFLOW_A$ — AD9016 only. Overflow data output for Data Bank "A." Logic HIGH indicates the analog input is greater than $+V_{SENSE}$ when OVERFLOW INHIBIT pin is LOW (−5.2V).

D_{5A} — AD9016 only. Most significant bit (MSB) digital data output of Data Bank "A."

D_{1A}–D_{4A} — AD9016 only. D_{1A} through D_{4A} digital data outputs from Data Bank "A."

D_{0A} — AD9016 only. Least significant bit (LSB) digital data output of Data Bank "A."

$DATA\ READY_A$ — AD9016 only. Output Data of Bank "A" are valid at the rising edge of the $DATA\ READY_A$ pulse. Bank "A" carries every other sample of the A/D conversion; Bank "B" carries the remaining samples.

DIGITAL $-V_S$ — Negative digital supply pins, nominally −5.2V.

ANALOG $-V_S$ — Negative analog supply pins, nominally −5.2V.

$OVERFLOW_B$ — AD9016 only. Overflow data output for Data Bank "B." Logic HIGH indicates analog input is greater than $+V_{SENSE}$ when OVERFLOW INHIBIT pin is LOW (−5.2V).

D_{5B} — AD9016 only. Most significant bit (MSB) digital data output of Data Bank "B."

D_{0B}	AD9016 only. Least significant bit (LSB) digital data output of Data Bank "B."
DATA $READY_B$	AD9016 only. Output data of Bank "B" are valid at the rising edge of the DATA $READY_B$ pulse. Bank "B" carries every other sample of the A/D conversion; Bank "A" carries the remaining samples.
HYSTERESIS	The hysteresis control voltage varies the amount of hysteresis in the internal comparators. This pin normally floats at −3.17V; making pin more positive increases the hysteresis of the internal comparators.
MIDSCALE V_{REF}	The midpoint tap on the internal reference ladder; can be connected to an external voltage to improve integral linearity of the A/D converter.
ENCODE	ECL-compatible noninverted input of the encode command. The conversion cycle begins on the rising edge of the ENCODE signal.
$\overline{\text{ENCODE}}$	ECL-compatible inverted input of the encode command, used when a differential encode signal is used. $\overline{\text{ENCODE}}$ should be tied to a voltage corresponding to the midpoint of the encode signal when a single-ended encode signal is used.
$-V_{SENSE}$	Voltage sense line to the most negative reference voltage of the resistor ladder. The sense line is intended for connection to a high impedance node and has limited current capability. It is intended to be used to null offset at the bottom of the reference ladder.
$-V_{REF}$	The negative reference voltage applied to the internal resistor ladder.
D_0	AD9006 only. Least significant bit (LSB) of the output data.
D_1–D_4	AD9006 only. D_1 through D_4 digital data outputs.
D_5	AD9006 only. Most significant bit (MSB) of digital data output.
OVERFLOW	AD9006 only. Overflow data output. Logic HIGH indicates the analog input is greater than $+V_{SENSE}$ when OVERFLOW INHIBIT pin is LOW (−5.2V).
DATA READY	AD9006 only. Output data are valid at the rising edge of the DATA READY pulse.
$\overline{\text{DATA READY}}$	AD9006 only. Output data valid at the falling edge of the $\overline{\text{DATA READY}}$ pulse.

Analog Bandwidth
The analog input frequency at which the spectral power of the fundamental frequency (as determined by FFT analysis) is reduced by 3dB.

Aperture Delay (t_A)
The delay between the rising edge of the ENCODE command (or falling edge of $\overline{\text{ENCODE}}$) and the instant at which the analog input is sampled.

Aperture Uncertainty (Jitter)
The sample-to-sample variation in aperture delay.

Data Ready Output Delay (t_{DR})
The delay between the 50% point of the falling edge of the ENCODE command (or rising edge of $\overline{\text{ENCODE}}$) and the −1.3V point of the leading edge of the DATA READY pulse.

Differential Nonlinearity
The deviation of any code from an ideal 1LSB step.

Effective Number of Bits (ENOB)
Signal-to-noise ratio (see definition below) is expressed in dB; but can also be expressed in Effective Number of Bits (ENOB) if ENOB is related to full scale inputs as follows:

$$ENOB = (SNR - 1.78)/6.02$$

ENOB is calculated with a sine wave curve fit method.

In-Band Harmonics
The rms value of the fundamental divided by the rms value of the worst of the first six harmonics.

Integral Nonlinearity
This specification (often called "linearity error") is the deviation of the transfer function from a reference line and is expressed in either % or ppm of full scale range, or in fractions of 1LSB. In the AD9006 and AD9016 devices, this spec is measured in fractions of 1LSB and uses a best-fit straight line determined by a least square curve fit.

Output Delay (t_{OD})
The delay between the 50% point of the rising edge of the ENCODE command (or falling edge of $\overline{\text{ENCODE}}$) and the −1.3V point of output data.

Output Time Skew
Bit-to-bit time variations among Bits D_0 to D_5 and the overflow bit. In the AD9006 and AD9016 specifications, time skew includes HIGH-to-LOW and LOW-to-HIGH transitions of the digital output bits.

Overvoltage Recovery Time
The amount of time required for the converter to recover to 6-bit accuracy after an analog input overvoltage signal of 150% is reduced to the valid range of the converter.

Pipeline Delay
This is equal to one clock cycle and is the delay between the 50% points on the rising edges of two successive ENCODE commands (or falling edges of $\overline{\text{ENCODE}}$ commands).

Power Supply Rejection Ratio
The ratio of the change in power supply voltage to a corresponding change in input offset voltage. In the AD9006 and AD9016 units, $+V_S$ (+5V) or $-V_S$ (−5.2V) are within ±5% of their nominal values for this test. Value shown in SPECIFICATIONS is worst case.

Signal-to-Noise Ratio (SNR)
The ratio of the rms signal amplitude to the rms value of "noise", which is defined as the sum of all other spectral components, including harmonics but excluding dc, with an analog input signal 1dB below full scale.

Transient Response
The time required for the converter to achieve 6-bit accuracy when a full scale step function input is applied to the unit.

Two-Tone Intermodulation Distortion (IMD) Rejection
The ratio of the power of a two-tone signal to the power of the strongest third-order IMD signal.

RECOMMENDED OPERATING CONDITIONS

Parameter	Input Voltage		
	Min	Nominal	Max
$+V_S$	+4.75	+5.00	+5.25
$-V_S$	−5.46	−5.20	−4.94
$+V_{REF}$	$-V_{REF}$	+1.0	+1.1
$-V_{REF}$	−1.1	−1.0	$+V_{REF}$
ANALOG INPUT	−1.0		+1.0

THEORY OF OPERATION

Refer to the block diagram of the AD9016 A/D converter.

"Flash" architecture used in the AD9006 and AD9016 units makes it unnecessary to use a track-and-hold (T/H) ahead of the converter in many applications. The analog input signal is impressed across 64 parallel comparator stages.

Bias points of these comparators are established by the voltages applied to the reference ladder via $+V_{REF}$, $MIDSCALE_{REF}$ and $-V_{REF}$.

The outputs of the comparators are applied to the decoding logic; from here, the data are applied to output latches as six bits of digital data and an overflow bit. The overflow bit can be used to stack converters to obtain additional bits of resolution and can also be used as a "flag" for indicating positive out-of-range inputs.

Capturing output data at the (guaranteed) encode rates of 470MSPS of the AD9016 is simplified by virtue of using two Data Ready pulses. Output data words alternate between Bank A and Bank B; this allows clocking demultiplexed data from the AD9016 at half the converter's sample rate.

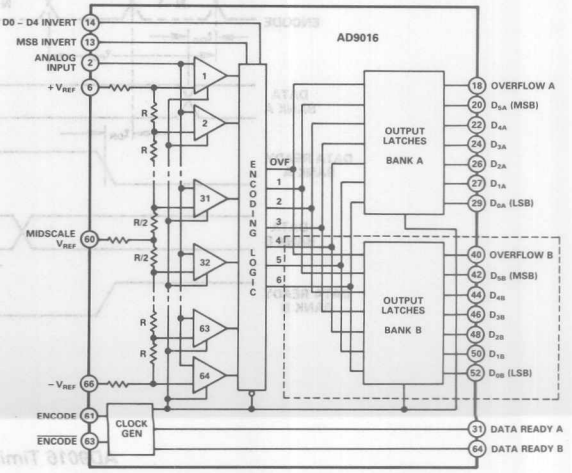
The Data Ready pulses track the propagation delay of the output data and relieve the need to build an external clock circuit for tracking prop delay over the full operating temperature range.

Demultiplexed ports connected to Bank A and Bank B allow the user to capture output data with 100K ECL logic even when the converter is operating at 470MSPS. The AD9016 introduces only one pipeline delay in the processing of these digital output data, thereby reducing the number of clock cycles required to obtain the digital representation of the analog input at the appropriate output port.

The analog input voltage range is determined by the user-supplied voltage references: $+V_{REF}$ and $-V_{REF}$. The references can be adjusted between −1V and +1V. In all cases, $+V_{REF}$ should be greater than $-V_{REF}$; and the differential voltage between the references should not exceed 2.1V. MIDSCALE V_{REF} can be used to improve the integral linearity of the converter.

Another attractive feature of the analog input characteristics of the AD9016 is its low input capacitance of 8pF. In many other flash converters, this value is three or four times larger, making them difficult to drive at high input frequencies.

For those applications in which a single output port is preferred, the recommended choice is the AD9006 A/D converter.



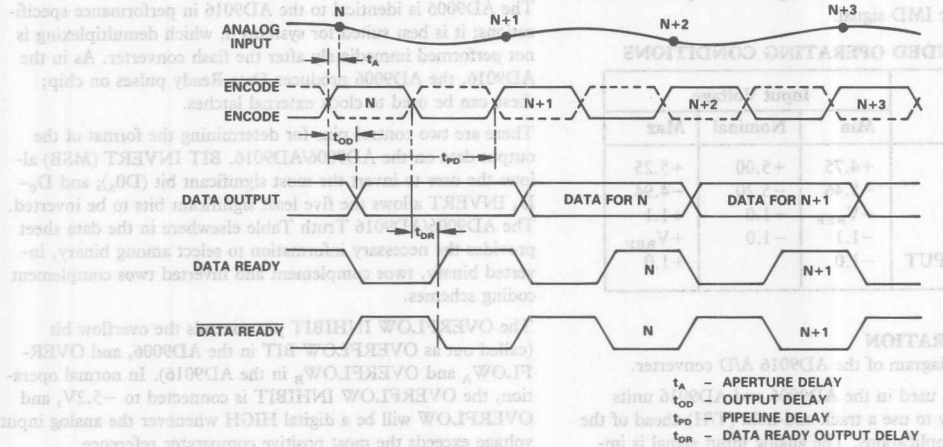
The AD9006 is identical to the AD9016 in performance specifications; it is best suited for systems in which demultiplexing is not performed immediately after the flash converter. As in the AD9016, the AD9006 produces Data Ready pulses on chip; these can be used to clock external latches.

There are two control pins for determining the format of the output data on the AD9006/AD9016. BIT INVERT (MSB) allows the user to invert the most significant bit ($D0_5$); and D_0–D_4 INVERT allows the five least significant bits to be inverted. The AD9006/AD9016 Truth Table elsewhere in the data sheet provides the necessary information to select among binary, inverted binary, twos complement and inverted twos complement coding schemes.

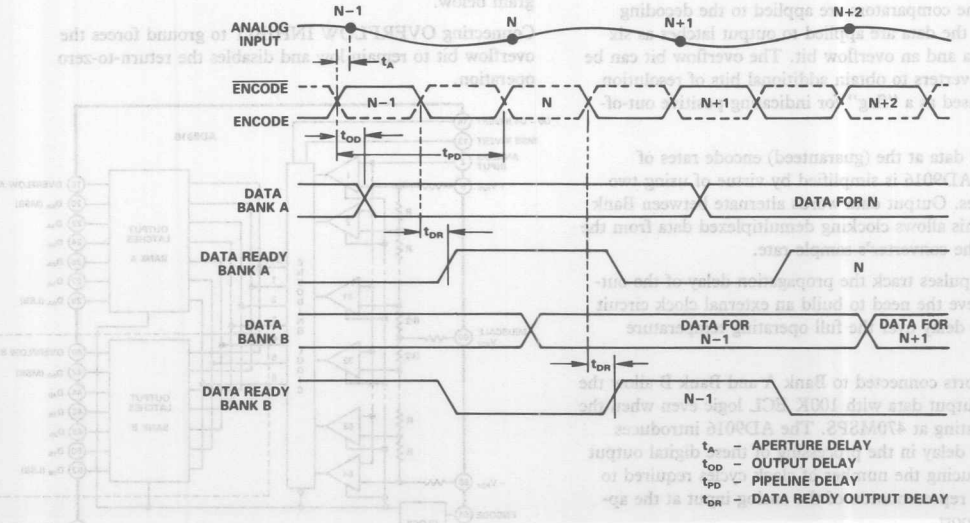
The OVERFLOW INHIBIT pin controls the overflow bit (called out as OVERFLOW BIT in the AD9006, and $OVERFLOW_A$ and $OVERFLOW_B$ in the AD9016). In normal operation, the OVERFLOW INHIBIT is connected to −5.2V, and OVERFLOW will be a digital HIGH whenever the analog input voltage exceeds the most positive comparator reference ($+V_{SENSE}$). The digital outputs (D_0– D_5) will be LOW, i.e., returned-to-zero operation.

This feature means two AD9006 devices can be cascaded or "stacked" to obtain seven-bit operation, as shown in the diagram below.

Connecting OVERFLOW INHIBIT to ground forces the overflow bit to remain low and disables the return-to-zero operation.



AD9016 Functional Block Diagram
(Dotted Area Not Included in AD9006)



Timing for the AD9006 and AD9016 is shown in their respective timing diagrams. In both illustrations, the complementary encode command is shown in dashed lines.

The DATA READY and $\overline{\text{DATA READY}}$ pulses of the AD9006 correspond, respectively, to the DATA READY BANK A and DATA READY BANK B pulses of the AD9016. As shown in the SPECIFICATIONS table, Data Ready Output Delay is slightly different in the two units: 3.2ns in the AD9006 and 3.6ns in the AD9016.

Availability and timing of a DATA READY pulse help in retrieving data from either the AD9006 or the AD9016. When setting system timing, the user simply takes into account the (single) pipeline delay and the Data Ready Output Delay (3.2ns in the AD9006; 3.6ns in the AD9016) and uses the next DATA READY (or $\overline{\text{DATA READY}}$ in the AD9006) to strobe the desired output into external circuits.

AD9006 Timing Diagram

AD9016 Timing Diagram

APPLYING THE AD9006/AD9016

Setting Reference Levels

The AD9006/AD9016 requires that the user provide two voltage references: $+V_{REF}$ and $-V_{REF}$. These two voltages are applied across the internal resistor ladder (nominally 80Ω) and determine the analog input range of the converter.

Care should be taken to assure that these references are driven from stable, low impedance sources. Reference connections should be capacitively coupled to ground to reduce interference generated by noise and/or digital switching.

Resistance between the reference connections and the point at which the first comparator threshold is connected causes offset errors. These errors, called "top and bottom of the ladder offsets," can be nulled out using the $+V_{SENSE}$ and $-V_{SENSE}$ connections. These sense lines are intended for connection only to high impedance (low current) nodes such as the input of an op amp.

Applying a voltage greater than 2.1V across the internal resistor ladder will cause current densities to exceed rated values and may cause permanent damage to the AD9006/AD9016.The amount of current available at the reference connections must be limited.

One method of nulling the offset errors is shown in Figure 1.

The Analog Devices AD1403 voltage reference supplies a stable 2.5V reference for the circuit, and R_{LIMIT} determines the range over which the reference can be adjusted. R_1 adjusts the voltage at the top of the internal reference ladder through the AD642/2N3904 combination. Feedback from the $+V_{SENSE}$ line causes the op amp to compensate for offset which appears at the top comparator threshold. The transistor limits the amount of current drawn directly from the op amp; resistors at the base and emitter of the transistor stabilize its operation.

Voltage at the bottom of the reference ladder is controlled in essentially the same way, using R_2 to adjust the reference ladder voltage; and using feedback from the $-V_{SENSE}$ connection to null any offset between the reference and the threshold of the bottom comparator.

The midpoint of the comparator reference ladder (MIDSCALE V_{REF}) is shown tied to ground in Figure 1. This allows the user to adjust the voltage reference for minimum integral nonlinearity. This feature becomes important in applications with reduced analog input ranges because integral nonlinearity increases under these conditions.

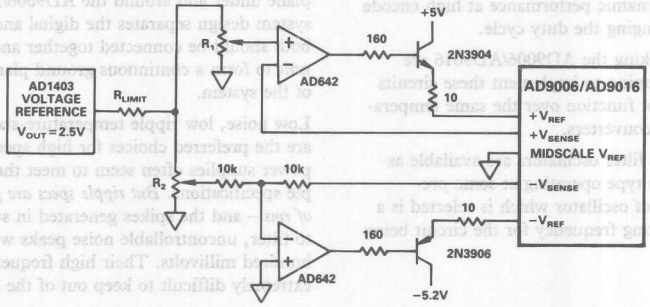


Figure 1. Reference Circuit

Driving the Analog Input

Careful design and layout of the AD9006/AD9016 have resulted in a typical input capacitance of 8pF (9.5pF max). This is low in comparison to most flash converters, but it is still a significant load at high input frequencies and must be taken into account when choosing a drive amplifier.

DC-coupled applications require the performance characteristics of a wide bandwidth, low distortion op amp such as the Analog Devices AD9611. AC-coupled applications at high frequencies may be better served by using a low distortion gain block for the driver.

Figure 2 illustrates possible connections for both approaches.

Regardless of which driving circuit is selected for the application, the overall dynamic performance of the amplifier is enhanced by inserting a small series resistor between the output of the amplifier and the analog input of the converter.

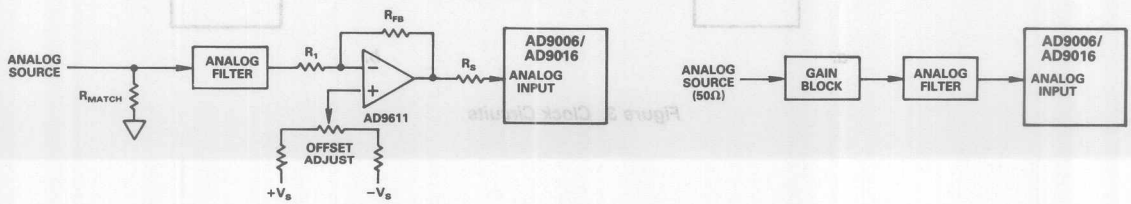

Figure 2. Analog Input Circuits

Clocking the Converter

The encode command circuits of the AD9006/AD9016 (ENCODE and $\overline{\text{ENCODE}}$) are designed to be driven by a differential ECL source.

A differential signal is recommended as the encode command to reduce jitter of the encode signal; increased jitter raises the noise floor of the converter. Full logic levels are preferred for triggering the clock circuits, but reduced levels can also be used. Caution should be exercised when using reduced-level encode commands because their slew rates will be decreased, which can raise the noise floor.

Refer again to the timing diagrams for the AD9006 and AD9016.

The rising edge of the ENCODE signal initiates the conversion process in the AD9006 unit. This same signal, delayed, becomes the DATA READY and complementary $\overline{\text{DATA READY}}$ pulses. Fast rise and fall times (<0.5ns) and "clean" edges are always required for encode commands, but are especially critical for high frequency analog signals.

In the AD9016, the leading edges of the DATA READY_A and DATA READY_B pulses are triggered by the trailing edge of an ENCODE command. Their trailing edges are triggered by the trailing edge of the next ENCODE command.

Although the AD9006/AD9016 is designed and tested to operate with a 50% duty cycle, the dynamic performance at high encode rates can be improved by changing the duty cycle.

Two possible methods of clocking the AD9006/AD9016 are shown in Figure 3. Users planning to implement these circuits need to be aware they may not function over the same temperature ranges possible with the converters.

Both ECL oscillators and saw filter oscillators are available as comercial products, with each type operating at some preselected frequency. The type of oscillator which is selected is a function of the desired operating frequency for the circuit being designed.

Layout and Power Supplies

Correct layout of high speed circuits is always critical, but is particularly important when both analog and digital signals are involved.

Analog signal paths should be kept as short as practical, and be properly terminated to avoid reflections and signal distortions. The analog input and voltage references should be kept away from digital signal paths; this reduces the possibility of capacitively coupling digital switching noise into the analog section of the circuit.

Digital signal paths should also be kept short, and digital run lengths should be matched because propagation delays through digital paths become significant at high data rates. Proper ECL terminations should be used at or near the packages containing successive gates.

Ideally, analog signal paths and digital signal paths should be routed as far away from one another as possible and should never closely parallel one another's paths. If they must cross, they should do so at right angles to avoid interference.

In any layout of high speed circuits, the layout of ground connections is the most important factor. To reduce noise and interference on the circuit ground, a double-sided copper-clad printed circuit board (PCB) is recommended. Every part of the board not used for components or conducting runs should be ground plane. Components are mounted on one side; the opposite side is used for power and signal connections.

It is especially important to retain the continuity of the ground plane under and around the AD9006/AD9016 converter. If the system design separates the digital and analog ground returns, both should be connected together and to ground close to the unit to form a continuous ground plane around the A/D section of the system.

Low noise, low ripple temperature-stable linear power supplies are the preferred choices for high speed circuits. Switching power supplies often seem to meet these criteria, including ripple specifications. *But ripple specs are generally expressed in terms of rms* – and the spikes generated in switchers can produce hard-to-filter, uncontrollable noise peaks with amplitudes of several hundred millivolts. Their high frequency components may be extremely difficult to keep out of the ground system.

If switching power supplies cannot be avoided for high speed designs, they should be *carefully* shielded and their outputs should be well filtered.

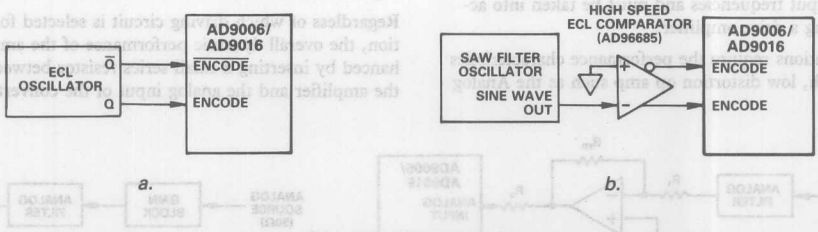

Figure 3. Clock Circuits

Every power supply line leading into a high speed PCB or data acquisition circuit must be carefully bypassed to its ground return to prevent noise from entering the circuit. Ceramic capacitors, ranging in value from 0.01μF to 0.1μF, should be used generously in the layout, mounted as closely as possible to the device or circuit being bypassed.

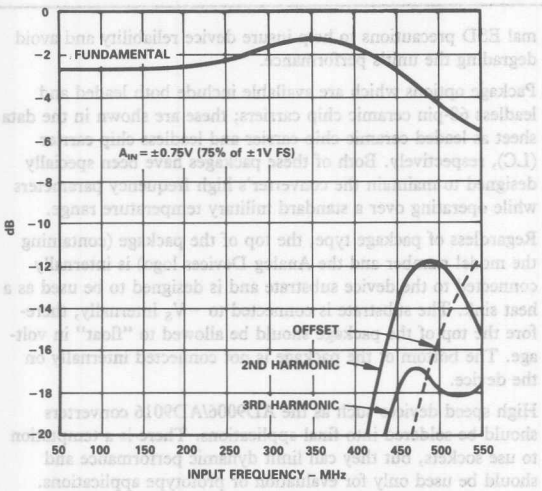
The capacitors which are used should have a high resonant frequency to insure they maintain their characteristics in the range of frequencies involved in the encoding process. Ceramic surface mount (chip) capacitors meet that requirement and are easily placed near the package connections.

At least one high quality tanatalum capacitor of 3μF– 20μF should be assigned to each power supply voltage, mounted as near as possible to the incoming power pins to minimize low frequency ripple.

Handling the AD9006/AD9016 Package

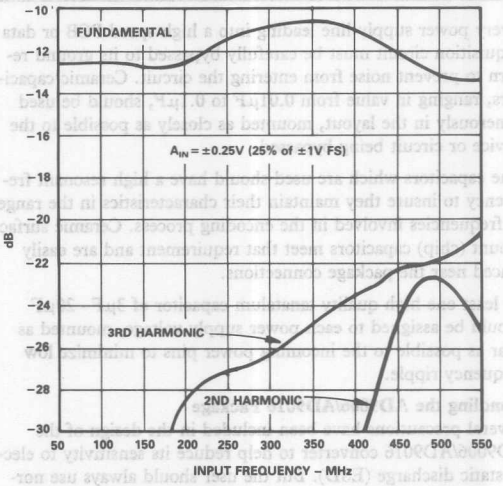
Several precautions have been included in the design of the AD9006/AD9016 converter to help reduce its sensitivity to electrostatic discharge (ESD). But the user should always use normal ESD precautions to help insure device reliability and avoid degrading the unit's performance.

Package options which are available include both leaded and leadless 68-pin ceramic chip carriers; these are shown in the data sheet as leaded ceramic chip carrier and leadless chip carrier (LC), respectively. Both of these packages have been specially designed to maintain the converter's high frequency parameters while operating over a standard military temperature range.



Regardless of package type, the top of the package (containing the model number and the Analog Devices logo) is internally connected to the device substrate and is designed to be used as a heat sink. The substrate is connected to $-V_S$ internally; therefore the top of the package should be allowed to "float" in voltage. The bottom of the package is not connected internally on the device.

High speed devices such as the AD9006/AD9016 converters should be soldered into final applications. There is a temptation to use sockets, but they can limit dynamic performance and should be used only for evaluation or prototype applications.



Step	Input Voltage (FS =±1.0V)	Binary		Offset Twos Complement

FEATURES
100MSPS Encode Rate
Very Low Input Capacitance – 16pF
Low Power – 1W
TTL Compatible Outputs
MIL-STD-883 Compliant Versions Available

APPLICATIONS
Radar Guidance
Digital Oscilloscopes/ATE Equipment
Laser/Radar Warning Receivers
Digital Radio
Electronic Warfare (ECM, ECCM, ESM)
Communication/Signal Intelligence

FUNCTIONAL BLOCK DIAGRAM

GENERAL DESCRIPTION

The AD9012 is an 8-bit, ultrahigh speed, analog-to-digital converter. The AD9012 is fabricated in an advanced bipolar process, which allows operation at sampling rates up to 100 megasamples/second. Functionally, the AD9012 is comprised of 256 parallel comparator stages whose outputs are decoded to drive the TTL compatible output latches.

The exceptionally wide large signal analog input bandwidth of 160MHz is due to an innovative comparator design and very close attention to device layout considerations. The wide input bandwidth of the AD9012 allows very accurate acquisition of high speed pulse inputs without an external track-and-hold. The comparator output decoding scheme minimizes false codes, which is critical to high speed linearity.

The AD9012 is available in two grades, one with 0.5LSB linearity and one with 0.75LSB linearity. Both versions are offered in an industrial grade, −25°C to +85°C, packaged in a 28-pin DIP and a 28-pin PLCC. The military temperature range devices, −55°C to +125°C, are available in ceramic DIP and LCC packages and are compliant to MIL-STD-883 Class B.

The AD9012 is available in versions compliant with MIL-STD-883. Refer to the Analog Devices Military Products Databook or current AD9012/883B data sheet for detailed specifications.

AD9012—SPECIFICATIONS

ABSOLUTE MAXIMUM RATINGS[1]

Positive Supply Voltage ($+V_S$) . . . . . +6V
Analog to Digital Supply Voltage Differential ($-V_S$) . . . 0.5V
Negative Supply Voltage ($-V_S$) . . . . . −6V
Analog Input Voltage . . . . . $-V_S$ to +0.5V
ENCODE Input Voltage . . . . . −0.5V to +5V
OVERFLOW INH Input Voltage . . . . . −5.2V to 0V
Reference Input Voltage ($+V_{REF} - V_{REF}$)[2] . −3.5V to +0.1V
Differential Reference Voltage 2.1V
Reference Midpoint Current . . . . . ±4mA
Digital Output Current 30mA
Operating Temperature Range
AD9012AQ/BQ/AP/AN/BP/BN . . . . . −25°C to +85°C

NOTES

[1]Absolute maximum ratings are limiting values, to be applied individually, and beyond which the serviceability of the circuit may be impaired. Functional operability under any of these conditions is not necessarily implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

[2]$+V_{REF} \geq -V_{REF}$ under all circumstances.

[3]Maximum junction temperature (t_J max) should not exceed +175°C for ceramic packages, and +150°C for plastic packages:

$t_J = PD\ (\theta_{JA}) + t_A$
$PD\ (\theta_{JC}) + t_C$

where

PD = power dissipation
θ_{JA} = thermal impedance from junction to ambient (°C/W)
θ_{JC} = thermal impedance from junction to case (°C/W)
t_A = ambient temperature (°C)
t_C = case temperature (°C)

typical thermal impedances are:

Ceramic DIP $\theta_{JA} = 56°C/W$; $\theta_{JC} = 20°C/W$
Plastic DIP $\theta_{JA} = 60°C/W$; $\theta_{JC} = 20°C/W$
Ceramic LCC $\theta_{JA} = 69°C/W$; $\theta_{JC} = 23°C/W$
PLCC $\theta_{JA} = 60°C/W$; $\theta_{JC} = 19°C/W$.

[4]Measured with Analog Input = 0V.

[5]Measured by FFT analysis where fundamental is −3dBc.

[6]Input slew rate derived from rise time (10% to 90%) of full-scale step input.

[7]Outputs terminated with two equivalent 'LS00 type loads. (See load circuit.)

[8]Measured from ENCODE into data out for LSB only.

[9]For full-scale step input, 8-bit accuracy is attained in specified time.

[10]Recovers to 8-bit accuracy in specified time, after 150% full-scale input overvoltage.

[11]Output time skew includes high-to-low and low-to-high transitions as well as bit-to-bit time skew differences.

[12]ENCODE signal rise/fall times should be less than 30ns for normal operation.

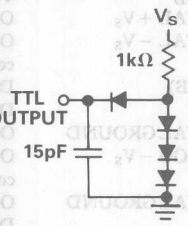
[13]Measured at 75MSPS encode rate. Harmonic data based on worst case harmonics.

[14]Analog input frequency = 1.23MHz.

[15]RMS signal to rms noise, including harmonics with 1.23MHz analog input signal.

[16]NPR measured @ 0.5MHz. Noise Source is 250mW (rms) from 0.5MHz to 8MHz.

[17]Supplies should remain stable within ±5% for normal operation.



[18]Measured at −5.2V ±5% and +5.0V ±5%.

Specifications subject to change without notice.

Recommended Operating Conditions

Parameter	Input Voltage Min	Nominal	Max
$-V_S$	−5.46	−5.20	−4.94
$+V_S$	+4.75	5.00	+5.25
$+V_{REF}$	$-V_{REF}$	0.0V	+0.1
$-V_{REF}$	−2.1	−2.0	$+V_{REF}$
Analog Input	$-V_{REF}$		$+V_{REF}$

LOAD CIRCUIT

EXPLANATION OF TEST LEVELS

Test Level I – 100% production tested.
Test Level II – 100% production tested at +25°C, and sample tested at specified temperatures.
Test Level III – Sample tested only.
Test Level IV – Parameter is guaranteed by design and characterization testing.
Test Level V – Parameter is a typical value only.
Test Level VI – All devices are 100% production tested at +25°C. 100% production tested at temperature extremes for extended temperature devices; sample tested at temperature extremes for commercial/industrial devices.

ORDERING GUIDE

Device	Linearity	Temperature Range	Package Option*
AD9012AQ	0.75LSB	−25°C to +85°C	Q-28
AD9012BQ	0.50LSB	−25°C to +85°C	Q-28

$V_{IN} < +V_{REF}$	0	X	X	X	X	X	X	X	X	0	X	X	X	X	X	X	X	X

3	HYSTERESIS	The Hysteresis control voltage varies the comparator hysteresis from 0mV to 10mV, for a change from $-5.2V$ to $-2.2V$ at the Hysteresis control pin.
4	$+V_{REF}$	The most positive reference voltage for the internal resistor ladder.
5	ANALOG INPUT	One of two analog input pins. Both analog input pins should be connected together.
6	ANALOG GROUND	One of two analog ground pins. Both analog ground pins should be connected together.
7	ENCODE	TTL level encode command input. ENCODE is rising edge sensitive.
8	DIGITAL $+V_S$	One of three positive digital supply pins (nominally $+5.0V$).
9	ANALOG GROUND	One of two analog ground pins. Both analog ground pins should be connected together.
10	ANALOG INPUT	One of two analog input pins. Both analog inputs should be connected together.
11	$-V_{REF}$	The most negative reference voltage for the internal resistor ladder.
12	REF_{MID}	The midpoint tap on the internal resistor ladder.
13	DIGITAL $+V_S$	One of three positive digital supply pins (nominally $+5.0V$)
14	DIGITAL $-V_S$	One of two negative digital supply pins (nominally $-5.2V$). Both digital supply pins should be connected together.
15	D_1 (LSB)	Digital data output. D_1 (LSB) is the least significant bit of the digital output word.
16-19	D_2-D_5	Digital data output.
20	DIGITAL GROUND	One of two digital ground pins. Both digital grounds pins should be connected together.
21, 22	ANALOG $-V_S$	One of two negative analog supply pins (nominally $-5.2V$). Both analog supply pins should be connected together.
23	DIGITAL GROUND	One of two digital ground pins. Both digital ground pins should be connected together.
24, 25	D_6, D_7	Digital data output.
26	D_8 (MSB)	Digital data output D_8 (MSB) is the most significant bit of the digital output word.
27	OVERFLOW	Overflow data output. Logic HIGH indicates an input overvoltage ($V_{IN} > +V_{REF}$), if OVERFLOW INHIBIT is enabled (overflow enabled, floating). See OVERFLOW INHIBIT.
28	DIGITAL $-V_S$	One of two negative digital supply pins (nominally $-5.2V$). Both digital supply pins should be connected together.

APPLICATION INFORMATION

The AD9012 is compatible with all standard TTL logic families. However, to operate at the highest encode rates, the supporting logic around the AD9012 will need to be equally fast. Two possible choices are the AS and the ALS families. Whichever of the TTL logic families is used, special care must be exercised to keep digital switching noise away from the analog circuits around the AD9012. The two most critical items are the digital supply lines and the digital ground return.

The input capacitance of the AD9012 is an exceptionally low 16pF. This allows the use of a wide range of input amplifiers, both hybrid and monolithic. To take full advantage of the 160MHz input bandwidth of the AD9012, a hybrid amplifier like the AD9610/AD9611 will be required. For those applications that do not require the full input bandwidth of the AD9012, some of the more traditional monolithic amplifiers, like the AD846, should work very well. Overall performance with monolithic amplifiers can be improved by inserting a 40Ω resistor in series with the amplifier output.

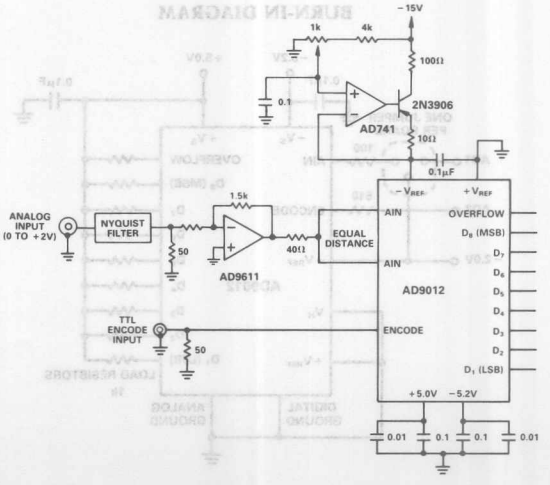
The output data is buffered through the TTL compatible output latches. All data is delayed by one clock cycle, in addition to the latch propagation delay (t_{PD}), before becoming available at the outputs. Both the analog-to-digital conversion cycle and the data transfer to the output latches, are triggered on the rising edge of the TTL compatible ENCODE signal (see timing diagram).

The AD9012 also incorporates a HYSTERESIS control pin which provides from 0 to 10mV of additional hysteresis in the comparator input stages. Adjustments in the HYSTERESIS control voltage may help to improve noise immunity and overall performance in harsh environments.

The OVERFLOW INHIBIT pin of the AD9012 determines how the converter handles overrange inputs (AIN≥ $+V_{REF}$). In the "enabled" state (floating at −5.2V), the OVERFLOW output will be at logic HIGH and all other outputs will be at logic LOW for overrange inputs (return-to-zero operation). In the "inhibited" state (tied to ground), the OVERFLOW output will be at logic LOW for overrange inputs, and all other digital outputs will be at logic HIGH (nonreturn-to-zero operation).

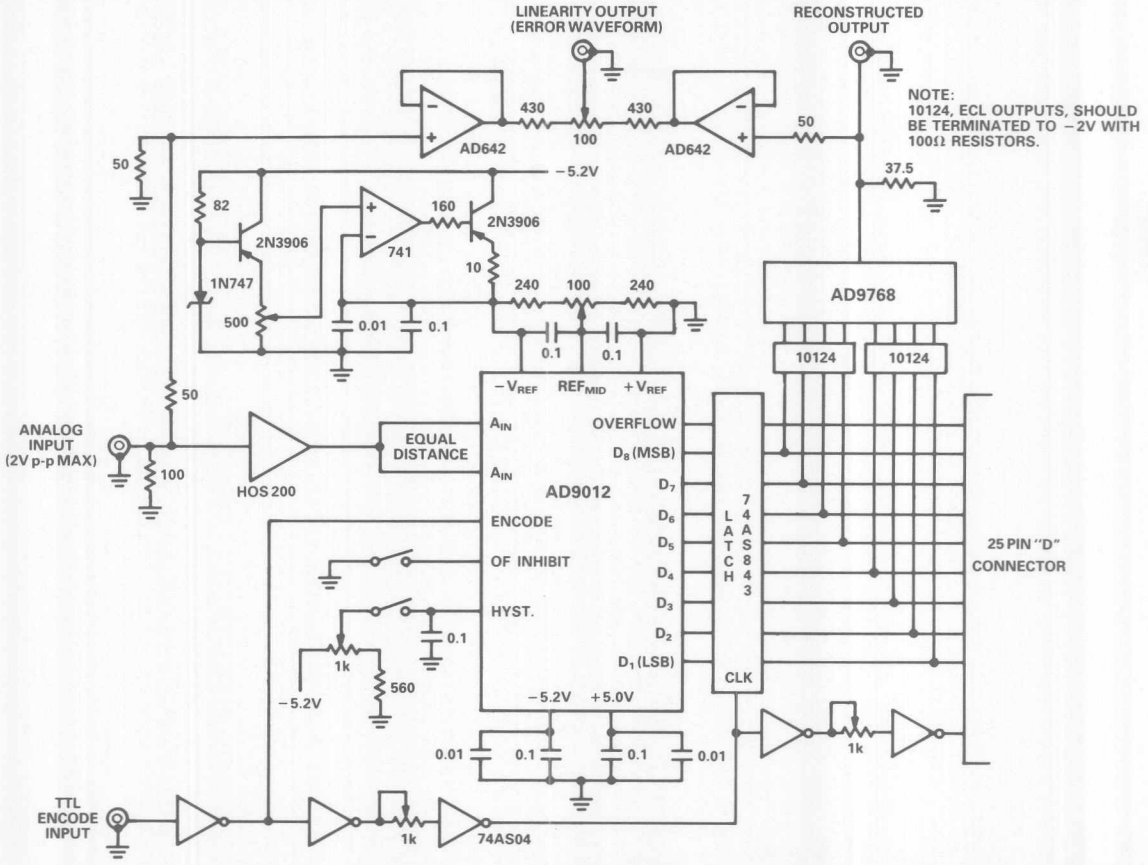
The AD9012 provides outstanding error rate performance. This is due to tight control of comparator offset matching and a fault tolerant decoding stage. Additional improvements in error rate are possible through the addition of hysteresis (see HYSTERSIS control pin). This level of performance is extremely important in fault sensitive applications like digital radio (QAM).

Dramatic improvements in comparator design and construction give the AD9012 excellent dynamic characteristics, namely SNR (signal-to-noise ratio). The 160MHz input bandwidth and low error rate performance give the AD9012 an SNR of 47dB with a 1.23MHz input. High SNR performance is particularly important in broadcast video applications where signals may pass through the converter several times before the processing is complete. Pulse signature analysis, commonly performed in advanced radar receivers, is another area that is especially dependent on high quality dynamic performance.



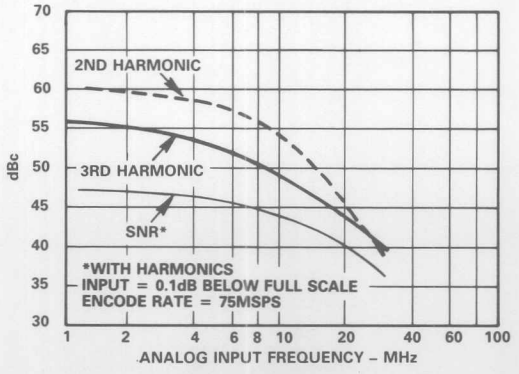
LAYOUT SUGGESTIONS

Designs using the AD9012, like all high-speed devices, must follow a few basic layout rules to insure optimum performance. Essentially, these guidelines are meant to avoid many of the problems associated with high-speed designs. The first requirement is for a substantial ground plane around and under the AD9012. Separate ground plane areas for the digital and analog components may be useful, but the separate grounds should be connected together at the AD9012 to avoid the effects of "ground loop" currents.



The second area that requires an extra degree of attention involves the three reference inputs, $+V_{REF}$, REF_{MID}, and $-V_{REF}$. The $+V_{REF}$ input and the $-V_{REF}$ input should both be driven from a low impedance source (note that the $+V_{REF}$ input is typically tied to analog ground). A low drift amplifier should provide satisfactory results, even over an extended temperature range. Adjustments at the REF_{MID} input may be useful in improving the integral linearity by correcting any reference ladder skews.

The reference inputs should be adequately decoupled to ground through 0.1μF chip capacitors to limit the effects of system noise on conversion accuracy. The power supply pins must also be decoupled to ground to improve noise immunity; 0.1μF and 0.01μF chip capacitors should be very effective.



The analog input signal is brought into the AD9012 through two separate input pins. It is very important that the two input pins be driven symetrically with equal length electrical connections. Otherwise, aperture delay errors may degrade converter performance at high frequencies.

GENERAL DESCRIPTION

The AD9014 is a high performance 14-bit analog-to-digital converter designed to provide extremely wide dynamic range for spectrum analysis and imaging applications. It is a complete subsystem that requires the user to provide only power and an encode clock.

Careful consideration to the design of the converter, along with the development of several custom linear and digital IC building blocks, has resulted in a converter with unsurpassed dynamic range. Sampling at 10 MSPS, the spurious free dynamic range (SFDR) is a function of analog input frequency as shown below:

Analog Input	SFDR
100 kHz	90 dB (min)
2.3 MHz	90 dB (min)
4.3 MHz	86 dB (min)
10 MHz	72 dB (typ)

For the AD9014, DNL is 0.5 LSBs; transient response to 0.01% is 30 ns; full power bandwidth is 50 MHz; and the SNR is 75 dB. These attributes make the AD9014 ideal for applications that require fast sampling of relatively low frequency analog input signals, such as CCD and infrared imaging.

The AD9014 consists of two custom hybrids mounted on a small multilayer PCB. The hybrid differential track-and-hold achieves first order cancellation of the even order harmonics while suppressing common-mode noise. The second hybrid is a digitally corrected subranging A/D encoder that uses two 8-bit flash converters with two bits of overlap correction. Decoupling capacitors have been designed into both hybrids, as well as on the mother board. This onboard decoupling simplifies the task of successfully using the converter.

Each AD9014 is tested at a 10 MSPS encode rate at multiple analog input frequencies. For each input frequency, the FFT testing is repeated for various A_{IN} power levels. This technique verifies that the dynamic performance of the converter is maintained even when low level input signals are being digitized.

Two versions of the AD9014 are available. The AD9014K is intended for applications that require the highest possible spurious free dynamic range performance; the AD9014J is intended for applications where spectral domain information is not as important, such as in imaging. The analog input signal can be applied to the ADC via either an onboard SMA connector or through a pin connected to the connector. Logic is ECL; the encode clock is differential ECL.

Consult Analog Devices about special needs and/or specific applications.

Supply Voltages ($\pm V_S$)	±18 V

NOTES

[1]Absolute maximum ratings are limiting values to be applied individually, and beyond which the serviceability of the circuit may be impaired. Functional operation under any of these conditions is not necessarily implied. Exposure to absolute maximum ratings for extended periods of time may affect device reliability.

[2]Cooling air at 500 LFPM applied. Parts must have 30 second warm-up time.

[3]The capacitance seen at the analog input pin of the T/H hybrid is 2.0 pF.

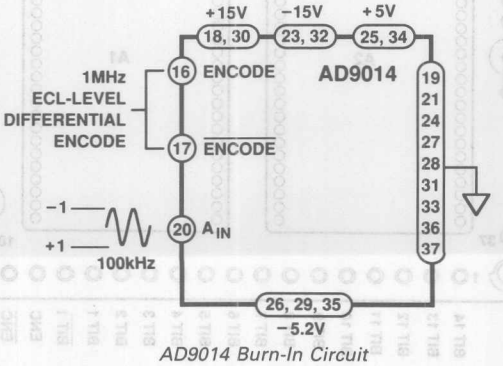
[4]Consult factory regarding availability of units with lower spur levels; units capable of 10.24 MSPS rates are also available.

[5]Measured from rising edge of Encode Command (Pin 16) to instant of final change in data output.

[6]During factory testing, analog input is applied to AD9014 via onboard SMA connector.

[7]Power of the analog input is swept from −1 dBFS to approximately −60 dBFS; and multiple FFTs are taken for "K-grade" parts. The specification is equivalent to the spurious free dynamic range (SFDR).

[8]Including noise and all spurs.



[9]10Kvoltage-level-compatible. Encode inputs have 50 Ω differential terminations.

[10]Each digital output is terminated to −5.2 V through a 2 kΩ resistor with a 1k resistor in series with the output. See diagram elsewhere in data sheet.

ORDERING GUIDE

AD9014 PIN CONFIGURATION

AD9014 PIN DESCRIPTIONS

Pin No.	Name	Function
1 through 14	Bit 14 (LSB) through Bit 1 (MSB)	True ECL outputs. Each is internally terminated to −5.2 V through a 2 kΩ resistor and has limited drive capability; a 1 kΩ isolation resistor is connected in series with the output. Additional termination will increase current spikes within the hybrid, and possibly degrade A/D performance. These pins should be interfaced to ECL receivers or latches located as close as possible to the AD9014. Positive full scale is represented by all "1"s. (See equivalent circuit elsewhere in data sheet.)
15	$\overline{\text{Bit 1 (MSB)}}$	Complement of Bit 1 (see above).
16	ENCODE	Differential ECL ENCODE inputs; 50 Ω internal terminations. User-supplied ENCODE command should contain smallest possible amount of jitter for optimum performance.
17	$\overline{\text{ENCODE}}$	
18, 30	+15 V	Analog supply pins; decoupling capacitors included on AD9014 card.
19, 24, 27	AGND	Analog ground; should be connected to low impedance ground plane.
20	A_{IN}	Analog input to AD9014; interface is via either SMA connector or this pin, nominally 75 Ω input impedance. (See equivalent circuit.)
21	AGND	Signal ground reference; should be connected to signal source reference.
22	AGND	Signal ground reference; should be connected to signal source reference.
23, 32	−15 V	Analog supply pins; decoupling capacitors included on AD9014 card.
25, 34	+5 V	V_{CC} analog supply pins; decoupling included on AD9014 board.
26, 35	−5.2 V	V_{EE} analog supply pins; decoupling included on AD9014 board.
31, 33, 36	AGND	Analog ground; should be connected to low impedance ground plane.
29	−5.2 V	Digital V_{EE} supply pin.
28, 37	DGND	Digital ground; should be connected to low impedance ground plane.

		MIN	TYP	MAX
t_W	ENCODE COMMAND PULSE WIDTH	10ns		50% OF DUTY CYCLE
t_E	SPACING BETWEEN ENCODE COMMANDS	100ns		
t_C	CONVERSION TIME		65ns	
t_A	ACQUISITION TIME *		35ns	
t_{OD}	OUTPUT DELAY [DRIVING SINGLE 10K LOGIC GATE ADJACENT TO UNIT (SEE APPLICATIONS SECTION)]		30ns	

*APPLICATIONS WITH SLIGHTLY FASTER SAMPLING RATE (10.24 MSPS) WILL HAVE ACQUISITION TIME WHICH IS APPROXIMATELY 2ns SHORTER

AD9014 Timing Diagram

The AD9014 is a two-step subranging analog to digital converter that provides extremely wide dynamic range performance. Its major system building blocks include a single to differential amplifier; track and hold amplifier; 8-bit main range flash ADC; 16-bit-linear, 8-bit DAC; clamped monolithic summation amplifier; 8-bit residue flash ADC; and digital adder logic.

The AD9014 consists of two custom hybrids mounted on a small multilayered PCB. It was made possible by a judicious combination of innovative design topologies, new custom chips, and mature manufacturing processes including laser trimming of thin-film resistors.

Subranging architecture has been utilized in numerous ADCs and has proven to be an efficient way to obtain wide dynamic range at high sampling rates. Briefly, a single-ended analog input signal is converted to a balanced differential signal that is "sampled and held" by a track and hold amplifier. This held value is then digitized by the main range 8-bit flash A/D converter. The resulting 8-bit word is converted back to an analog value via a 16-bit-linear, 8-bit DAC and is compared to the "held" value via a high accuracy, clamped summation amplifier. The difference of the two signals is then digitized by a second 8-bit flash ADC. In the final step, the two 8-bit words are combined via digital adder logic.

Refer to the block diagram of the AD9014 on the first page of this data sheet. The track and hold hybrid accomplishes two functions. First, the single-ended analog input is converted to a balanced differential signal via an extremely low distortion single to differential amplifier. The 75 Ω input impedance of the AD9014 can be regarded as the feed-forward resistor of this amplifier. Second, the resultant balanced signal is then sampled and held for digitization by the encoder hybrid.

In previous ADCs, the track and hold (T/H) has been the most significant source of harmonic and nonharmonic spurs. To help avoid this in the AD9014, approximately half the power dissipation and one of the two hybrids is dedicated to the track and hold function. A differential T/H architecture is utilized to obtain first order cancellation of the even-order harmonics. The sampling switch (or bridge) is driven by a pair of closed-loop amplifiers to minimize aperture induced harmonics. The acquisition time of the AD9014 is approximately 35 ns.

Differential architecture used in the AD9014 T/H is extended to the encoder section of the AD9014. All circuit elements are differential to minimize the generation of spurs, increase the common-mode noise suppression, and improve performance over temperature.

Two 8-bit flash converters are used to achieve the 10 MSPS encode rate; each converter provides data approximately 8 ns after it receives an encode command. The main range converter provides the MSB information, which is loaded into the digital adder circuits and is also applied to the DAC. The residue converter provides the LSB information. Two overlap or correction bits are utilized in the digital correction logic where the two 8-bit words are combined into the final 14-bit digital output.

In addition to the track-and-hold, the digital-to-analog converter looms as a large contributor of spurs. The DAC in the AD9014 utilizes unique differential diode switching current sources and laser-trimmed thin film resistors. This optimizes the performance of the ADC as a function of temperature and time.

Laser trimmed thin film resistors are inherently stable over time. Any resistor shifts that occur are transparent to the user matched counterpart. The trimmed DAC settles to 16-bit accuracy in approximately 10 ns.

The output of the DAC is compared to the held dc value via a clamped summation amplifier. This amplifier is set for a gain of 10 V/V and drives the residue 8-bit flash converter. It settles in 35 ns and comes out of overdrive in 5 ns. The settling time of this amplifier is the major factor affecting the maximum sample rate of the AD9014.

The final major source of spurs are the nonlinearities in the two flash converters. Differential nonlinearity (DNL) and integral nonlinearity (INL) errors in the main range converter determine how much of the error correction budget is actually used.

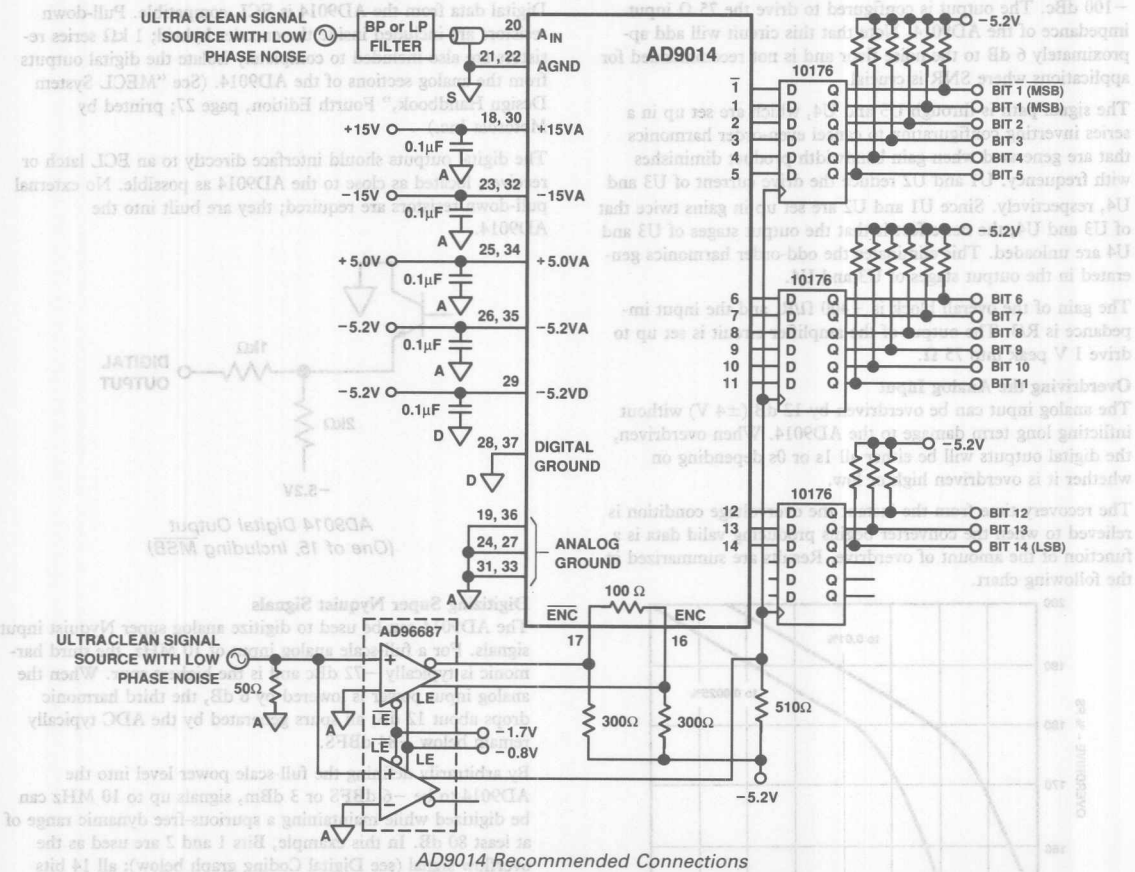
If the INL of the residue converter is sufficiently large, nonlinearities of the main range converter set the DNL of the AD9014 at the digitally compensated subranging points. If the main range converter is sufficiently linear, the DNL of the residue converter sets the overall AD9014 DNL. The flash converters used in the AD9014 are inherently linear; die are screened by probe testing before they are used in the encoder hybrid.

Finally, the two 8-bit digital words from the main range and residue flash converters are latched into a 16-bit register, where they are added to form the 14-bit digital output word. The actual error correction takes place in this adder. If the analog input exceeds positive or negative full scale, the digital output remains, respectively, at all "1" or all "0"; it does not roll over.

USING THE AD9014

The AD9014 A/D converter has been carefully designed to offer users the widest possible dynamic range. Each unit is dynamically tested before it is shipped. Great care has been taken in the design of the AD9014 to simplify its application so that users can easily duplicate the performance measured at the factory.

A well designed, "clean" printed circuit board (PCB) with separate power and ground planes is necessary; a multilayered board is recommended. Wire-wrap techniques often used in prototypes will materially diminish spectral performance. The figure labeled AD9014 Recommended Connections provides details regarding application of the unit.

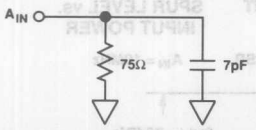


Driving the Differential Encode Input

A differential ECL encode signal is required for the AD9014. This signal should be as "clean" and fast (100K ECL equivalent) as possible, with a minimum amount of jitter.

Excessive jitter on the encode command manifests itself as a wider "skirt" around the analog input fundamental, which degrades the observed SNR and masks information which may be under the skirt. This may not be important in frequency domain applications since the generation of harmonic and nonharmonic spurs is unaffected.

One method of generating a "clean" differential ECL encode signal is to use a spectrally pure low phase noise sine wave to drive an AD96687 ultrafast ECL comparator, as shown in the "AD9014 Recommended Connections" figure on the next page. (Signal generators such as the HP 8642A and Rohde & Schwarz SMHU can be used.)



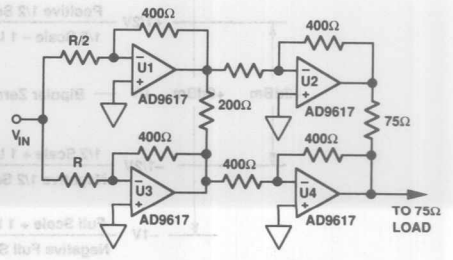
Careful consideration must be given to routing the encode signal. The comparator should be located as close as possible to the AD9014. The inputs to and outputs from the AD96687 should be as short as possible and terminated right at the unit.

AD9014 Recommended Connections

Matching the Analog Input Impedance

As described in the Theory of Operations, the analog input impedance into the track and hold is 75 Ω ‖ 7 pF. This is shown graphically in the figure below.

AD9014 Analog Input Circuit



The Analog input signal can be applied to the ADC either via the SMA connector or through Pin 20. The drive source should be matched to the impedance of the ADC. The AD9014 can be set up for a 50 Ω system by soldering the appropriate resistor between Pins 20 and 21. This option will be installed at the factory if "−50" is added to the part number when the order is placed.

Driving the Analog Input

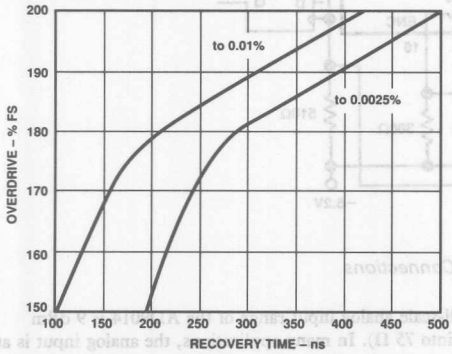
Special care must be taken to ensure that the analog input signal is not compromised before it reaches the A/D converter. Any required filtering should be done as close to the AD9014 as possible, and away from any digital lines.

The full-scale analog input range of the AD9014 is 9 dBm (±1 V into 75 Ω). In many applications, the analog input is at a much lower level and must be amplified to meet the full-scale range of the AD9014. The optimum way to achieve this amplification depends largely on the application.

For frequency domain applications, the circuit shown below is recommended when gain is required. This configuration works well for analog input frequencies through 10 MHz without introducing spurs that degrade the ADC's capabilities. At

Low-Distortion Drive Circuit for AD9014

2.3 MHz and 2 V p–p output, all spurs generated are less than −100 dBc. The output is configured to drive the 75 Ω input impedance of the AD9014. Note that this circuit will add approximately 6 dB to the noise floor and is not recommended for applications where SNR is crucial.



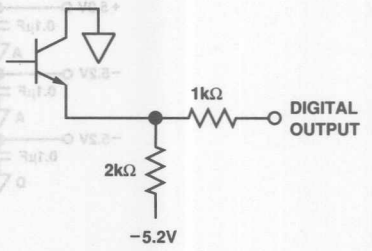
The signal path is through U3 and U4, which are set up in a series inverting configuration to cancel even-order harmonics that are generated when gain bandwidth product diminishes with frequency. U1 and U2 reduce the drive current of U3 and U4, respectively. Since U1 and U2 are set up in gains twice that of U3 and U4, the net effect is that the output stages of U3 and U4 are unloaded. This eliminates the odd-order harmonics generated in the output stages of U3 and U4.

The gain of the overall block is +400 Ω/R, and the input impedance is R/3. The output of the amplifier circuit is set up to drive 1 V peak into 75 Ω.

Overdriving the Analog Input

The analog input can be overdriven by 12 dB (±4 V) without inflicting long term damage to the AD9014. When overdriven, the digital outputs will be either all 1s or 0s depending on whether it is overdriven high or low.

The recovery time from the instant the overvoltage condition is relieved to when the converter begins producing valid data is a function of the amount of overdrive. Results are summarized in the following chart.

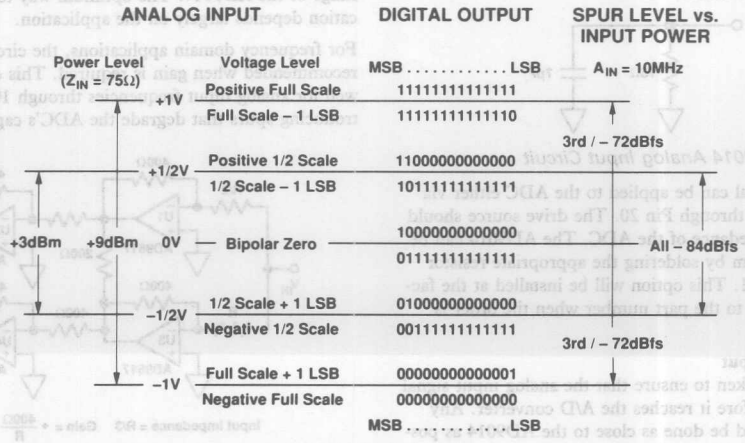


Overvoltage Recovery Time

Collecting the Digital Output Data

Digital data from the AD9014 is ECL compatible. Pull-down resistors are included inside the encoder hybrid; 1 kΩ series resistors are also included to completely isolate the digital outputs from the analog sections of the AD9014. (See "MECL System Design Handbook," Fourth Edition, page 27; printed by Motorola Inc.)

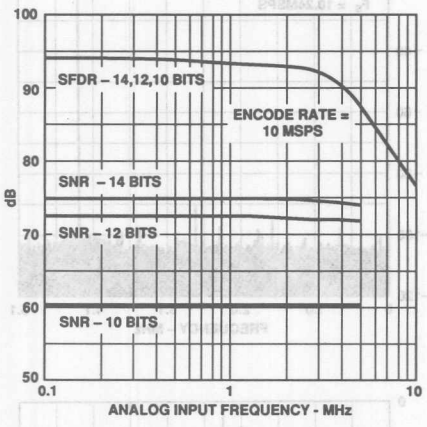
The digital outputs should interface directly to an ECL latch or receiver, located as close to the AD9014 as possible. No external pull-down resistors are required; they are built into the AD9014.



AD9014 Digital Output
(One of 15, Including $\overline{MSB}$)

Digitizing Super Nyquist Signals

The AD9014 can be used to digitize analog super Nyquist input signals. For a full-scale analog input of 10 MHz, the third harmonic is typically −72 dBc and is the highest spur. When the analog input power is lowered by 6 dB, the third harmonic drops about 12 dB; all spurs generated by the ADC typically remain below −84 dBFS.



By arbitrarily defining the full-scale power level into the AD9014 to be −6 dBFS or 3 dBm, signals up to 10 MHz can be digitized while maintaining a spurious-free dynamic range of at least 80 dB. In this example, Bits 1 and 2 are used as the overflow signal (see Digital Coding graph below); all 14 bits from the converter must be used, are valid, and should be processed.

AD9014 Digital Coding

Utilizing Fewer than 14 Bits

In some cases it is advantageous to ignore the AD9014's LSBs. As an example, if a previously designed DSP or buffer memory is able to process only 10- or 12-bit words, retrofitting the system using the AD9014 may provide significant improvements.

AD9014 SFDR and SNR vs. Frequency

The spurious free dynamic range (SFDR) of any A/D is a function of the converter linearity, while the "number of bits" of the converter's output affects the level of the noise floor. The level of the internally generated spurs will not rise as bits are omitted, but the noise floor rises for each bit that is dropped. The chart below summarizes the AD9014 SFDR as a function of the number of bits being processed.

Noise Figure Estimates

An estimate of the noise figure of the AD9014 can be calculated from information contained in the specification table. It is defined as the degradation of the signal-to-noise ratio as an analog signal passes through the device.

Since the AD9014 has no gain, the noise figure can be determined by comparing the noise level at the output to the noise at the input. For a 50 Ω system, the input noise can be determined using Boltzmann's Constant, the absolute temperature, and the bandwidth. For a 1 Hz bandwidth at room temperature, this value is −174 dBm/Hz.

The noise level at the output of the AD9014 can be calculated from the specified signal to noise-ratio (SNR) which is 75 dB. Since the full-scale analog input signal is +9 dBm, the noise level at the output of the AD9014 is −66 dBm for the 5 MHz band.

The noise figure can be determined using the following equation:

$$NF = Output\ Noise - 10\log_{10}(BWo/BWi) - Input\ Noise\ Level$$

where BWo = 5 MHz and BWi = 1 Hz

For the AD9014, the noise figure calculates to:

$$NF = -66\ dB - 67\ dB - (-174\ dB) = 41\ dB$$

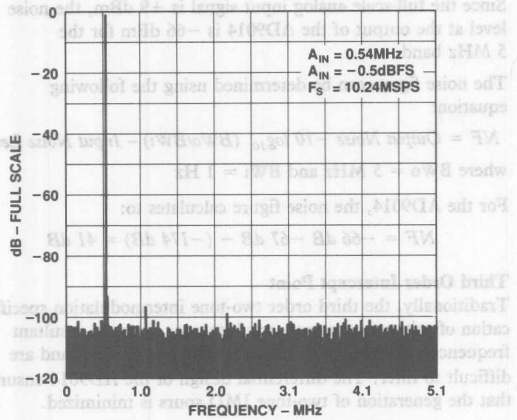
Third Order Intercept Point

Traditionally, the third order two-tone intermodulation specification of mixers is the most troublesome, since the resultant frequencies are very close to the fundamental signals and are difficult to filter. The differential design of the AD9014 ensures that the generation of two-tone IMD spurs is minimized.

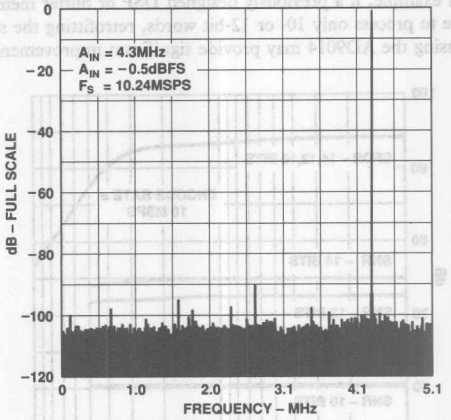
The two-tone IMD intercept point for the AD9014 can be easily estimated for a given frequency if the harmonic suppression of the IMD spur levels is known (or can be measured). As shown in the typical performance section of the data sheet, for 2 dBm (−7 dBFS) analog input tones of 2.3 MHZ and 2.4 MHz, the relevant IMD spurs are located at 2.2 MHz and 2.5 MHz, and are −95 dBm (−102 dBFS).

The following equation can be used to determine the converter's intercept point:

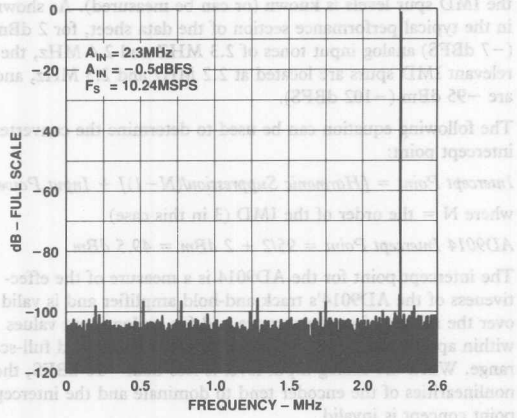
$$Intercept\ Point = [Harmonic\ Suppression/(N-1)] + Input\ Power$$



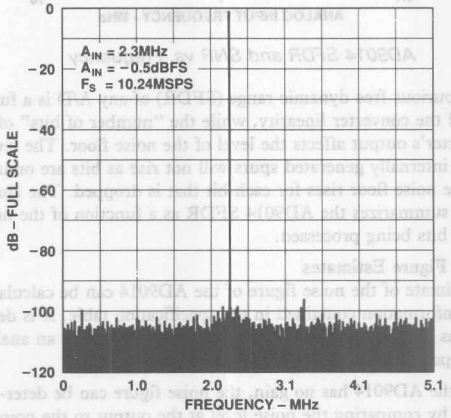
where N = the order of the IMD (3 in this case)



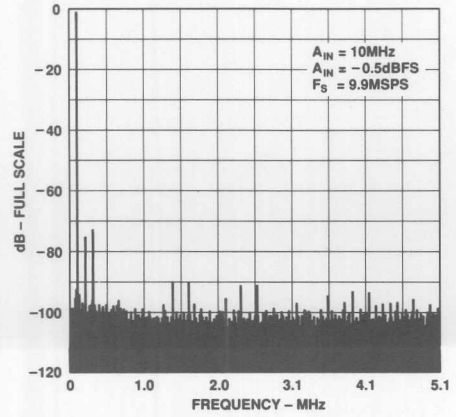
$$AD9014\ Intercept\ Point = 95/2 + 2\ dBm = 49.5\ dBm$$



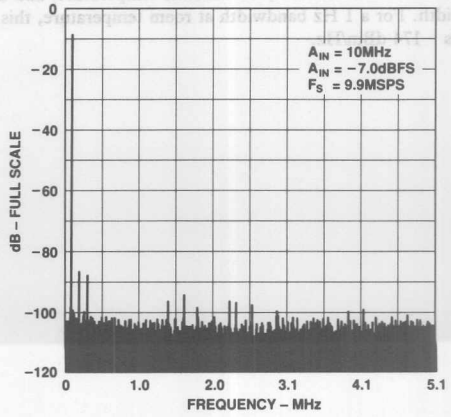
The intercept point for the AD9014 is a measure of the effectiveness of the AD9014's track-and-hold amplifier and is valid over the relevant frequency range and for analog input values within approximately 10 dB of the converter's specified full-scale range. When the analog input level is less than −10 dBFS, the nonlinearities of the encoder tend to dominate and the intercept point concept is invalid.

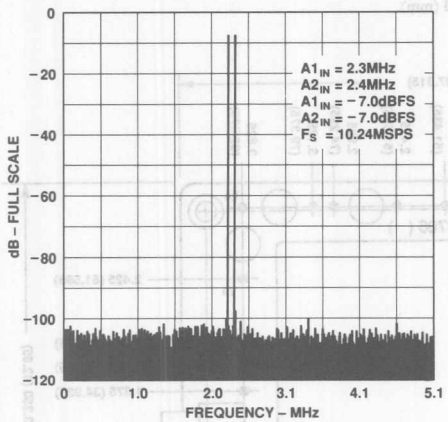


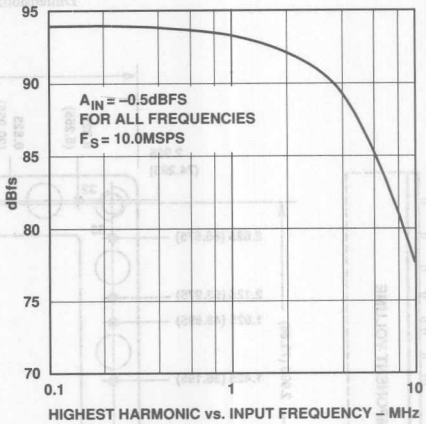
TYPICAL AD9014K SPECTRAL PERFORMANCE

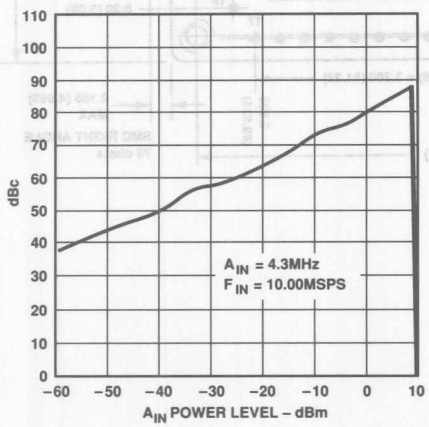


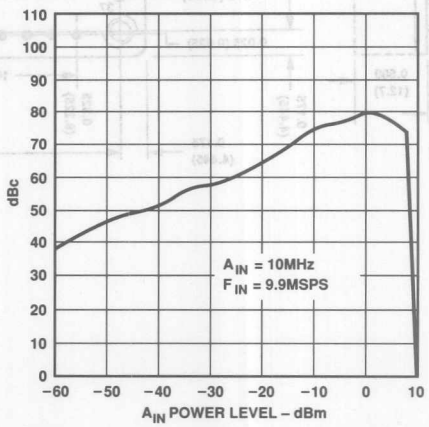
Five-sample average of 8,192-point FFTs; all harmonics are aliased.

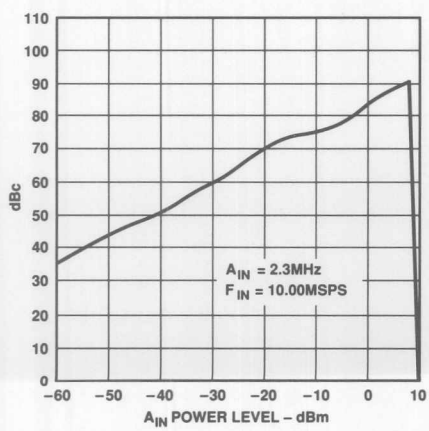


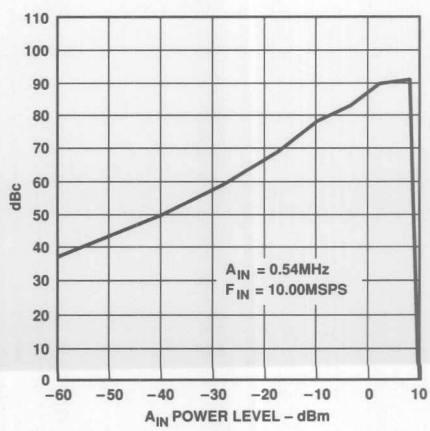












AD9014K TYPICAL PERFORMANCE

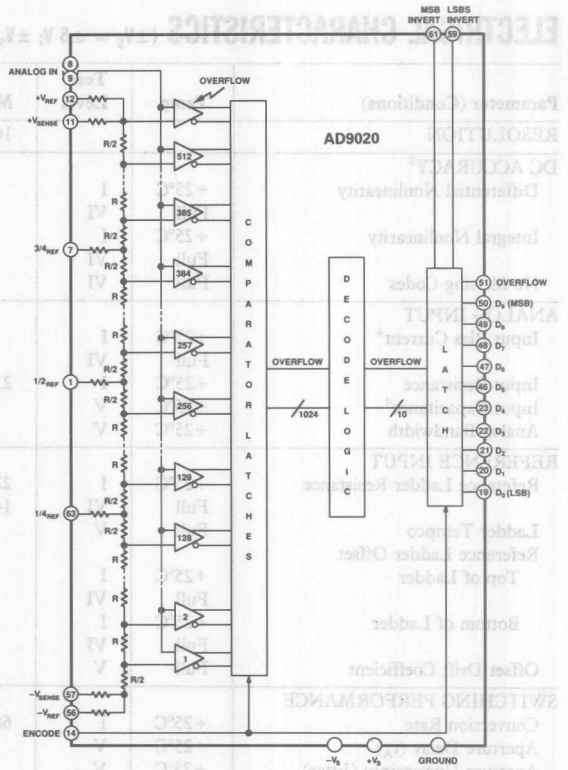
OUTLINE DIMENSIONS

Dimensions shown in inches and (mm).

AD9020



FEATURES

- Monolithic 10-Bit/60 MSPS Converter
- TTL Outputs
- Bipolar (±1.75 V) Analog Input
- 56 dB SNR @ 2.3 MHz Input
- Low (45 pF) Input Capacitance
- MIL-STD-883 Compliant Versions Available

APPLICATIONS

- Digital Oscilloscopes
- Medical Imaging
- Professional Video
- Radar Warning/Guidance Systems
- Infrared Systems

FUNCTIONAL BLOCK DIAGRAM

GENERAL DESCRIPTION

The AD9020 A/D converter is a 10-bit monolithic converter capable of word rates of 60 MSPS and above. Innovative architecture using 512 input comparators instead of the traditional 1024 required by other flash converters reduces input capacitance and improves linearity.

Encode and outputs are TTL-compatible, making the AD9020 an ideal candidate for use in low power systems. An overflow bit is provided to indicate analog input signals greater than $+V_{SENSE}$.

Voltage sense lines are provided to insure accurate driving of the $\pm V_{REF}$ voltages applied to the units. Quarter-point taps on the resistor ladder help optimize the integral linearity of the unit.

Either 68-pin ceramic leaded (gull wing) packages or ceramic LCCs are available and are specifically designed for low thermal impedances. Two performance grades for temperatures of both 0 to +70°C and −55°C to +125°C ranges are offered to allow the user to select the linearity best suited for each application. Dynamic performance is fully characterized and production tested at +25°C. MIL-STD-883 units are available.

The AD9020 A/D Converter is available in versions compliant with MIL-STD-883. Refer to the Analog Devices Military Products Databook or current AD9020/883B data sheet for detailed specifications.

$+V_S$	
$-V_S$	−6 V

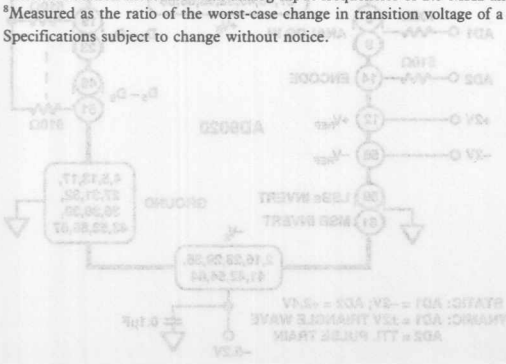
NOTES

[1]Absolute maximum ratings are limiting values to be applied individually, and beyond which the serviceability of the circuit may be impaired. Functional operability is not necessarily implied. Exposure to absolute maximum rating conditions for an extended period of time may affect device reliability.

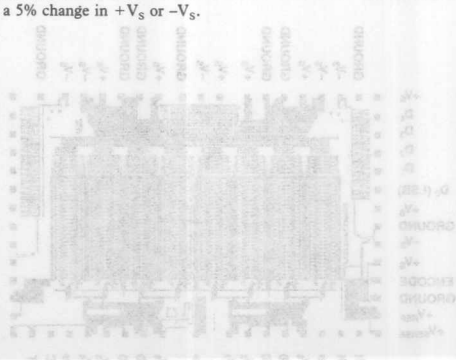
[2]Typical thermal impedances (part soldered onto board): 68-pin leaded ceramic chip carrier: θ_{JC} = 1°C/W; θ_{JA} = 17°C/W (no air flow); θ_{JA} = 15°C/W (air flow = 500 LFM). 68-pin ceramic LCC: θ_{JC} = 2.6°C/W; θ_{JA} = 15°C/W (no air flow); θ_{JA} = 13°C/W (air flow = 500 LFM).

[3]$3/4_{REF}$, $1/2_{REF}$, and $1/4_{REF}$ reference ladder taps are driven from dc sources at +0.875 V, 0 V, and −0.875 V, respectively. Accuracy of the overflow comparator is not tested and not included in linearity specifications.

[4]Measured with ANALOG IN = $+V_{SENSE}$.



[5]Output delay measured as worst-case time from 50% point of the rising edge of ENCODE to 50% point of the slowest rising or falling edge of D_0–D_9. Output skew measured as worst-case difference in output delay among D_0–D_9.



[6]RMS signal to rms noise with analog input signal 1 dB below full scale at specified frequency.

[7]Intermodulation measured with analog input frequencies of 2.3 MHz and 3.0 MHz at 7 dB below full scale.

[8]Measured as the ratio of the worst-case change in transition voltage of a single comparator for a 5% change in $+V_S$ or $-V_S$.

Specifications subject to change without notice.

EXPLANATION OF TEST LEVELS
Test Level

I – 100% production tested.
II – 100% production tested at +25°C, and sample tested at specified temperatures.
III – Sample tested only.
IV – Parameter is guaranteed by design and characterization testing.
V – Parameter is a typical value only.
VI – All devices are 100% production tested at +25°C. 100% production tested at temperature extremes for extended temperature devices; sample tested at temperature extremes for commercial/industrial devices.

AD9020 PIN DESCRIPTIONS

Pin No.	Name	Function
1	$1/2_{REF}$	Midpoint of internal reference ladder.
2, 16, 28, 29, 35, 41, 42, 54, 64	$-V_S$	Negative supply voltage; nominally −5.0 V ±5%.
3, 6, 15, 18, 25, 30, 33, 34, 37, 40, 45, 52, 55, 65, 68	$+V_S$	Positive supply voltage; nominally +5 V ±5%.
4, 5, 13, 17, 27, 31, 32 36, 38, 39, 43, 53, 66, 67	GROUND	All ground pins should be connected together and to low-impedance ground plane.
7	$3/4_{REF}$	Three-quarter point of internal reference ladder.
8, 9	ANALOG IN	Analog input; nominally between ±1.75 V.
11	$+V_{SENSE}$	Voltage sense line to most positive point on internal resistor ladder. Normally +1.75 V.
12	$+V_{REF}$	Voltage force connection for top of internal reference ladder. Normally driven to provide +1.75 V at $+V_{SENSE}$.
14	ENCODE	TTL-compatible convert command used to begin digitizing process.
19–23, 46–50	D_0–D_9	TTL-compatible digital output data.
51	OVERFLOW	TTL-compatible output indicating ANALOG IN > $+V_{SENSE}$.
56	$-V_{REF}$	Voltage force connection for bottom of internal reference ladder. Normally driven to provide −1.75 V at $-V_{SENSE}$.
57	$-V_{SENSE}$	Voltage sense line to most negative point on internal resistor ladder. Normally −1.75 V.
59	LSBs INVERT	Normally grounded. When connected to $+V_S$, lower order bits (D_0–D_8) are inverted.
61	MSB INVERT	Normally grounded. When connected to $+V_S$, most significant bit (MSB; D_9) is inverted.
63	$1/4_{REF}$	One-quarter point of internal reference ladder.

THEORY OF OPERATION

Refer to the AD9020 block diagram. As shown, the AD9020 uses a modified "flash", or parallel, A/D architecture. The analog input range is determined by an external voltage reference ($+V_{REF}$ and $-V_{REF}$), nominally ±1.75 V. An internal resistor ladder divides this reference into 512 steps, each representing two quantization levels. Taps along the resistor ladder ($1/4_{REF}$, $1/2_{REF}$ and $3/4_{REF}$) are provided to optimize linearity. Rated performance is achieved by driving these points at 1/4, 1/2 and 3/4, respectively, of the voltage reference range.

The A/D conversion for the nine most significant bits (MSBs) is performed by 512 comparators. The value of the least significant bit (LSB) is determined by a unique interpolation scheme between adjacent comparators. The decoding logic processes the comparator outputs and provides a 10-bit code to the output stage of the converter.

Flash architecture has an advantage over other A/D architectures because conversion occurs in one step. This means the performance of the converter is limited primarily by the speed and matching of the individual comparators. In the AD9020, an innovative interpolation scheme takes advantage of flash architecture but minimizes the input capacitance, power and device count usually associated with that method of conversion.

These advantages occur because of using only half the normal number of input comparator cells to accomplish the conversion. In addition, a proprietary decoding scheme minimizes error codes. Input control pins allow the user to select from among Binary, Inverted Binary, Twos Complement and Inverted Twos Complement coding (See AD9020 Truth Table).

APPLICATIONS

Many of the specifications used to describe analog/digital converters have evolved from system performance requirements in these applications. Different systems emphasize particular specifications, depending on how the part is used. The following applications highlight some of the specifications and features that make the AD9020 attractive in these systems.

Wideband Receivers

Radar and communication receivers (baseband and direct IF digitization), ultrasound medical imaging, signal intelligence and spectral analysis all place stringent ac performance requirements on analog-to-digital converters (ADCs). Frequency domain characterization of the AD9020 provides signal-to-noise ratio (SNR) and harmonic distortion data to simplify selection of the ADC.

Receiver sensitivity is limited by the *Signal-to-Noise Ratio (SNR)* of the system. The SNR for an ADC is measured in the frequency domain and calculated with a Fast Fourier Transform (FFT). The SNR equals the ratio of the fundamental component of the signal (rms amplitude) to the rms value of the "noise." The noise is the sum of all other spectral components, including harmonic distortion, but excluding dc.

Good receiver design minimizes the level of spurious signals in the system. Spurious signals developed in the ADC are the result of imperfections in the device transfer function (nonlinearities, delay mismatch, varying input impedance, etc.). In the ADC, these spurious signals appear as Harmonic Distortion. Harmonic Distortion is also measured with an FFT and is specified as the ratio of the fundamental component of the signal (rms amplitude) to the rms value of the worst case harmonic (usually the 2nd or 3rd).

Two-Tone Intermodulation Distortion (IMD) is a frequently cited specification in receiver design. In narrow-band receivers, third-order IMD products result in spurious signals in the pass band of the receiver. Like mixers and amplifiers, the ADC is characterized with two, equal-amplitude, pure input frequencies. The IMD equals the ratio of the power of either of the two input signals to the power of the strongest third-order IMD signal. Unlike mixers and amplifiers, the IMD does not always behave as it does in linear devices (reduced input levels do not result in predictable reductions in IMD).

Performance graphs provide typical harmonic and SNR data for the AD9020 for increasing analog input frequencies. In choosing an A/D converter, always look at the dynamic range for the analog input frequency of interest. The AD9020 specifications provide guaranteed minimum limits at three analog test frequencies.

Aperture Delay is the delay between the rising edge of the ENCODE command and the instant at which the analog input is sampled. Many systems require simultaneous sampling of more than one analog input signal with multiple ADCs. In these situations, timing is critical and the absolute value of the aperture delay is not as critical as the matching between devices.

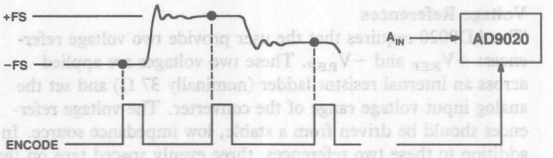
Aperture Uncertainty, or jitter, is the sample-to-sample variation in aperture delay. This is especially important when sampling high slew rate signals in wide bandwidth systems. Aperture uncertainty is one of the factors which degrades dynamic performance as the analog input frequency is increased.

Digitizing Oscilloscopes

Oscilloscopes provide amplitude information about an observed waveform with respect to time. Digitizing oscilloscopes must accurately sample this signal, without distorting the information to be displayed.

One figure of merit for the ADC in these applications is *Effective Number of Bits (ENOBs)*. ENOB is calculated with a sine wave curve fit and equals:

$$ENOB = N - LOG_2 [Error\ (measured)/Error\ (ideal)]$$



N is the resolution (number of bits) of the ADC. The measured error is the actual rms error calculated from the converter outputs with a pure sine wave input.

The *Analog Bandwidth* of the converter is the analog input frequency at which the spectral power of the fundamental signal is reduced 3 dB from its low frequency value. The analog bandwidth is a good indicator of a converter's slewing capabilities.

The *Maximum Conversion Rate* is defined as the encode rate at which the SNR for the lowest analog signal test frequency tested drops by no more than 3 dB below the guaranteed limit.

Imaging

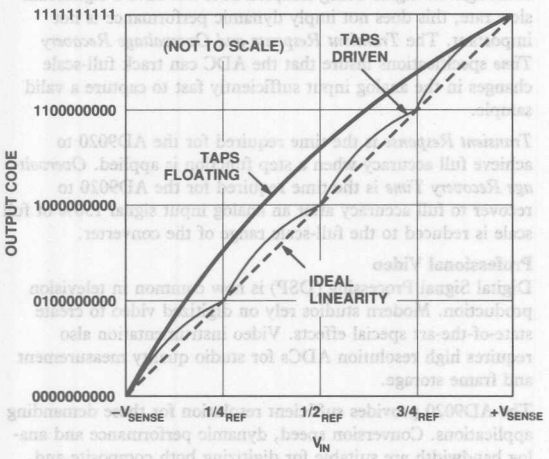
Visible and infrared imaging systems both require similar characteristics from ADCs. The signal input (from a CCD camera, or multiplexer) is a time division multiplexed signal consisting of a series of pulses whose amplitude varies in direct proportion to the intensity of the radiation detected at the sensor. These varying levels are then digitized by applying encode commands at the correct times, as shown below.

Imaging Application Using AD9020

The actual resolution of the converter is limited by the thermal and quantization noise of the ADC. The low frequency test for SNR or ENOB is a good measure of the noise of the AD9020. At this frequency, the static errors in the ADC determine the useful dynamic range of the ADC.

Although the signal being sampled does not have a significant slew rate, this does not imply dynamic performance is not important. The *Transient Response and Overvoltage Recovery Time* specifications insure that the ADC can track full-scale changes in the analog input sufficiently fast to capture a valid sample.

Transient Response is the time required for the AD9020 to achieve full accuracy when a step function is applied. *Overvoltage Recovery Time* is the time required for the AD9020 to recover to full accuracy after an analog input signal 150% of full scale is reduced to the full-scale range of the converter.



Professional Video

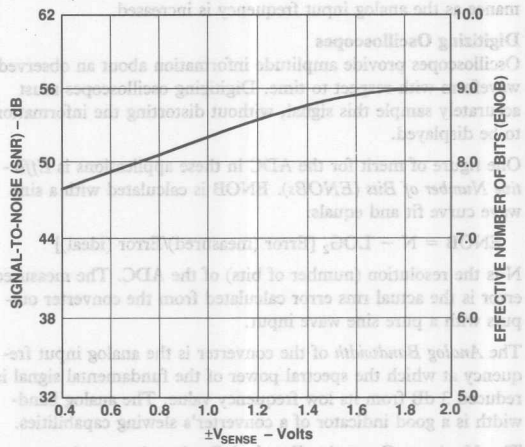
Digital Signal Processing (DSP) is now common in television production. Modern studios rely on digitized video to create state-of-the-art special effects. Video instrumentation also requires high resolution ADCs for studio quality measurement and frame storage.

The AD9020 provides sufficient resolution for these demanding applications. Conversion speed, dynamic performance and analog bandwidth are suitable for digitizing both composite and RGB video sources.

Voltage References

The AD9020 requires that the user provide two voltage references: $+V_{REF}$ and $-V_{REF}$. These two voltages are applied across an internal resistor ladder (nominally 37 Ω) and set the analog input voltage range of the converter. The voltage references should be driven from a stable, low impedance source. In addition to these two references, three evenly spaced taps on the resistor ladder ($1/4_{REF}$, $1/2_{REF}$, $3/4_{REF}$) are available. Providing a reference to these quarter points on the resistor ladder will improve the integral linearity of the converter and improve ac performance. (AC and dc specifications are tested while driving the quarter points at the indicated levels.) The figure below is not intended to show the transfer function of the ADC, but illustrates how the linearity of the device is affected by reference voltages applied to the ladder.

Effect of Reference Taps on Linearity



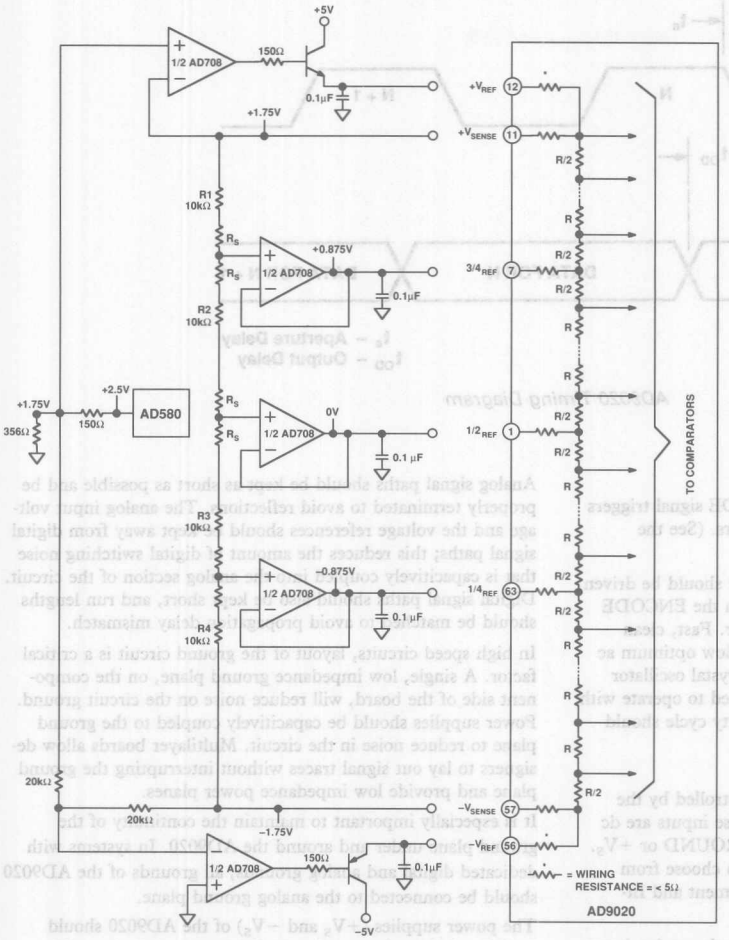
Resistance between the reference connections and the taps of the first and last comparators causes offset errors. These errors, called "top and bottom of the ladder offsets," can be nulled by using the voltage sense lines, $+V_{SENSE}$ and $-V_{SENSE}$, to adjust the reference voltages. Current through the sense lines should be limited to less than 100 μA. Excessive current drawn through the voltage sense lines will affect the accuracy of the sense line voltage.

The next page shows a reference circuit which nulls out the offset errors using two op amps and provides appropriate voltage references to the quarter-point taps. Feedback from the sense lines causes the op amps to compensate for the offset errors. The two transistors limit the amount of current drawn directly from the op amps; resistors at the base connections stabilize their operation. The 10 kΩ resistors (R1–R4) between the voltage sense lines form an external resistor ladder; the quarter point voltages are taken off this external ladder and buffered by an op amp. The actual values of resistors R1–R4 are not critical, but they should match well and be large enough (≥10 kΩ) to limit the amount of current drawn from the voltage sense lines.

be a potentiometer) are chosen to adjust the quarter-point voltage references, but are not necessary if R1–R4 match within 0.05%.

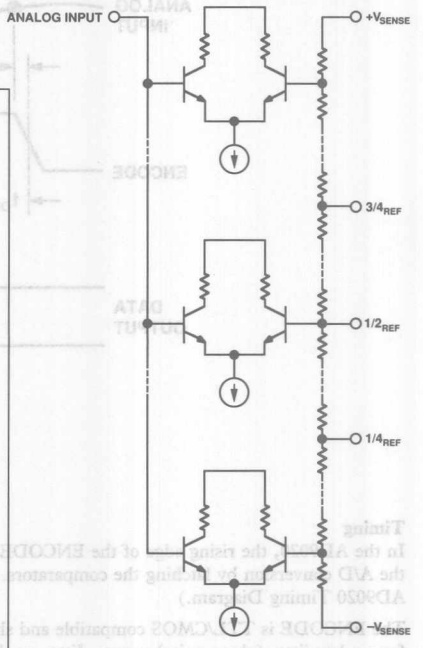
An alternative approach for defining the quarter-point references of the resistor ladder is to evaluate the integral linearity error of an individual device, and adjust the voltage at the quarter-points to minimize this error. This may improve the low frequency ac performance of the converter.

Performance of the AD9020 has been optimized with an analog input voltage of ±1.75 V (as measured at $\pm V_{SENSE}$). If the analog input range is reduced below these values, relatively larger differential nonlinearity errors may result because of comparator mismatches. As shown in the figure below, performance of the converter is a function of $\pm V_{SENSE}$.



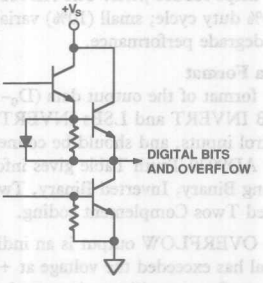
AD9020 SNR and ENOB vs. Reference Voltage

Applying a voltage greater than 4 V across the internal resistor ladder will cause current densities to exceed rated values, and may cause permanent damage to the AD9020. The design of the reference circuit should limit the voltage available to the references.

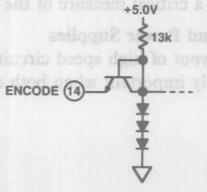


Analog Input Signal

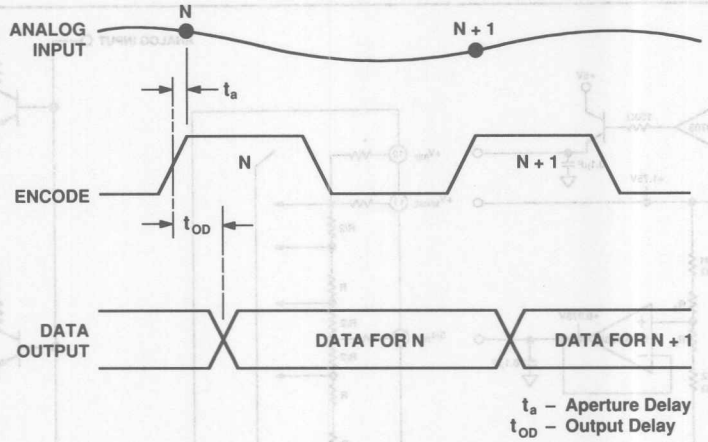
The signal applied to ANALOG IN drives the inputs of 512 parallel comparator cells (see Equivalent Analog Input figure). This connection typically has an input resistance of 7 kΩ, and input capacitance of 45 pF. The input capacitance is nearly constant over the analog input voltage range, as shown in the graph which illustrates that characteristic.



The analog input signal should be driven from a low distortion, low noise amplifier. A good choice is the AD9617, a wide bandwidth, monolithic operational amplifier with excellent ac and dc performance. The input capacitance should be isolated by a small series resistor (24 Ω for the AD9617) to improve the ac performance of the amplifier (see AD9020/PCB Evaluation Board Block Diagram).



AD9020 Reference Circuit



AD9020 Equivalent Analog Input

AD9020 Equivalent Digital Outputs

AD9020 Equivalent Encode Circuit

AD9020 Timing Diagram

Timing

In the AD9020, the rising edge of the ENCODE signal triggers the A/D conversion by latching the comparators. (See the AD9020 Timing Diagram.)

The ENCODE is TTL/CMOS compatible and should be driven from a low jitter (phase noise) source. Jitter on the ENCODE signal will raise the noise floor of the converter. Fast, clean edges will reduce the jitter in the signal and allow optimum ac performance. Locking the system clock to a crystal oscillator also helps reduce jitter. The AD9020 is designed to operate with a 50% duty cycle; small (10%) variations in duty cycle should not degrade performance.

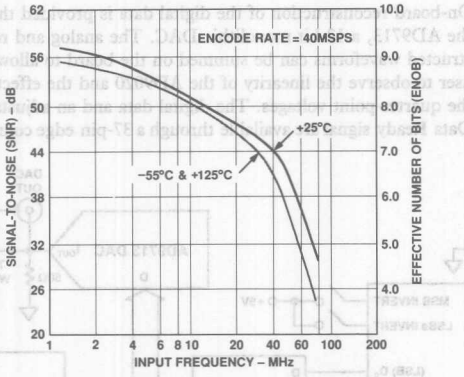
Data Format

The format of the output data (D_0– D_9) is controlled by the MSB INVERT and LSBs INVERT pins. These inputs are dc control inputs, and should be connected to GROUND or $+V_S$. The AD9020 Truth Table gives information to choose from among Binary, Inverted Binary, Twos Complement and Inverted Twos Complement coding.

The OVERFLOW output is an indication that the analog input signal has exceeded the voltage at $+V_{SENSE}$. The accuracy of the overflow transition voltage and output delay are not tested or included in the data sheet limits. Performance of the overflow indicator is dependent on circuit layout and slew rate of the encode signal. The operation of this function does not affect the other data bits (D_0–D_9). It is not recommended for applications requiring a critical measure of the analog input voltage.

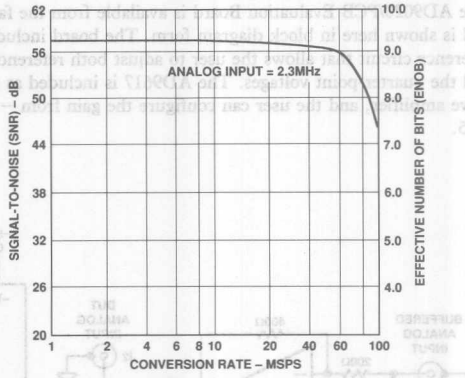
Layout and Power Supplies

Proper layout of high speed circuits is always critical but is particularly important when both analog and digital signals are involved.



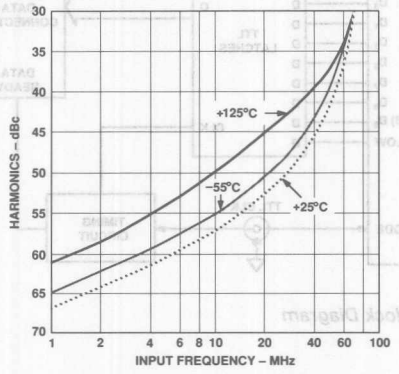
Analog signal paths should be kept as short as possible and be properly terminated to avoid reflections. The analog input voltage and the voltage references should be kept away from digital signal paths; this reduces the amount of digital switching noise that is capacitively coupled into the analog section of the circuit. Digital signal paths should also be kept short, and run lengths should be matched to avoid propagation delay mismatch.

In high speed circuits, layout of the ground circuit is a critical factor. A single, low impedance ground plane, on the component side of the board, will reduce noise on the circuit ground. Power supplies should be capacitively coupled to the ground plane to reduce noise in the circuit. Multilayer boards allow designers to lay out signal traces without interrupting the ground plane and provide low impedance power planes.



It is especially important to maintain the continuity of the ground plane under and around the AD9020. In systems with dedicated digital and analog grounds, all grounds of the AD9020 should be connected to the analog ground plane.

The power supplies ($+V_S$ and $-V_S$) of the AD9020 should be isolated from the supplies used for external devices; this further reduces the amount of noise coupled into the A/D converter. Sockets limit the dynamic performance and should be used only for prototypes or evaluation—PCK Elastomerics Part # CCS-68-55 is recommended for the LCC package. (Tel. 215-672-0787)



An evaluation board is available to aid designers and provide a suggested layout.

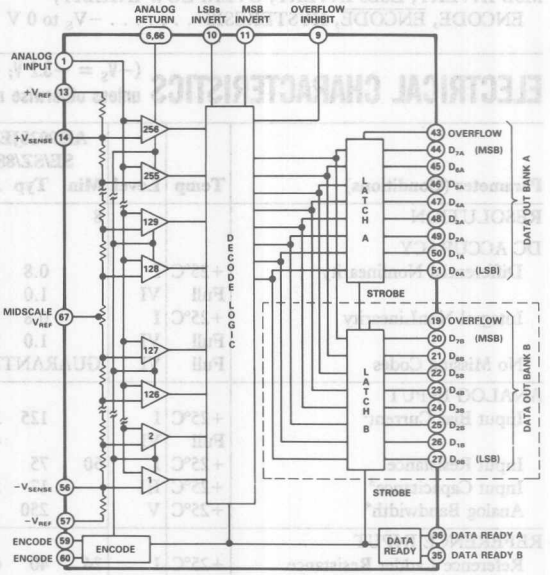
The overflow bit is always 0 except where noted in parentheses ( ). MSB INVERT and LSBs INVERT are considered dc controls.

AD9020 Truth Table

The AD9020/PCB Evaluation Board is available from the factory and is shown here in block diagram form. The board includes a reference circuit that allows the user to adjust both references and the quarter-point voltages. The AD9617 is included as the drive amplifier, and the user can configure the gain from −1 to −15.

On-board reconstruction of the digital data is provided through the AD9713, a 12-bit monolithic DAC. The analog and reconstructed waveforms can be summed on the board to allow the user to observe the linearity of the AD9020 and the effects of the quarter-point voltages. The digital data and an adjustable Data Ready signal are available through a 37-pin edge connector.

AD9020/PCB Evaluation Board Block Diagram



High Speed 8-Bit A/D Converters

AD9028/AD9038

FEATURES
300 MSPS Encode Rate
250 MHz Large Signal Input Bandwidth
Low Input Capacitance: 17 pF
Excellent SNR
Single −5.2 V Power Supply
Overflow Bit & Bit Invert Functions
1:2 Demultiplexed Outputs (AD9038)
MIL-STD-883-Compliant Versions Available

APPLICATIONS
Digital Oscilloscopes
Waveform Digitizers
Radar Receivers
Electronic Countermeasures

FUNCTIONAL BLOCK DIAGRAM

GENERAL DESCRIPTION

The AD9028 and AD9038 are ECL-compatible 8-bit, high speed flash analog-to-digital converters. Both are fabricated in an advanced bipolar VLSI process which ensures exceptionally wide analog input bandwidth (250 MHz) and encode rates up to 300 MSPS.

Output data for the AD9028 include Overflow and Data Ready signals; control pins allow the user to invert the MSB and/or LSBs. The AD9038 combines the features of the AD9028 with on-board demultiplexing circuits to provide two sets of output data. These ease the task of interfacing the converter by reducing the data rate to half the encode rate.

The analog input is designed for 0 to −2.0 volt operation. Sense pins for the $+V_{REF}$ and $-V_{REF}$ inputs allow full-scale calibration of the input range; a tap at the midpoint of the reference ladder is available to minimize integral nonlinearity. Dynamic performance is enhanced by driving the ANALOG RETURN pins with a buffered analog input; see the Applications section.

There are two linearity grades of each device. Commercial temperature ranges of 0 to +70°C and military temperature ranges of −55°C to +125°C are available. Both components are offered in a ceramic 68-pin LCC, and a ceramic 68-pin leaded package. These packages are specially designed for low thermal impedance.

The AD9028/AD9038 A/D Converter is available in versions compliant with MIL-STD-883. Refer to the *Analog Devices Military Products Databook* or current AD9028/AD9038/883B data sheet for detailed specifications.

AD9028/AD9038—SPECIFICATIONS

ABSOLUTE MAXIMUM RATINGS[1]

ANALOG INPUT . . . . . $-V_S$ to +0.5 V
ANALOG RETURN . . . . . 0 V to +2.0 V
$-V_S$ to GROUND . . . . . +0.5 V dc to −6.0 V dc
$+V_{REF}$, $-V_{REF}$, MIDSCALE V_{REF} . . . . . −2.1 V to +0.1 V
$+V_{REF}$ to $-V_{REF}$ . . . . . 2.1 V
MIDSCALE V_{REF}, $+V_{SENSE}$, $-V_{SENSE}$ Current . . . . ±4 mA
MSB INVERT, LSBs INVERT, OVERFLOW INHIBIT, ENCODE, $\overline{\text{ENCODE}}$, HYSTERESIS . . . . . $-V_S$ to 0 V
ENCODE to $\overline{\text{ENCODE}}$ . . . . . 4 V
Digital Output Current . . . . . 20 mA
ANALOG $-V_S$ to DIGITAL $-V_S$ . . . . . ±0.5 V
Operating Temperature Range
AD9028/AD9038KE/KZ/JE/JZ . . . . . 0 to +70°C
AD9028/AD9038TE/TZ/SE/SZ/883 . . . . . −55°C to +125°C
Maximum Junction Temperature[2] . . . . . +175°C
Lead Temperature (Soldering, 10sec) . . . . . +300°C
Storage Temperature Range . . . . . −65°C to +150°C

ELECTRICAL CHARACTERISTICS ($-V_S = -5.2$ V; $+V_{REF} = 0$ V; $-V_{REF} = -2$ V; ANALOG RETURN = 0 V, unless otherwise noted)

NOTES

[1]Absolute maximum ratings are limiting values to be applied individually, and beyond which the serviceability of the circuit may be impaired. Functional operability is not necessarily implied. Exposure to absolute maximum rating conditions for an extended period of time may affect device reliability.

[2]Typical thermal impedances:68-pin leaded ceramic chip carrier θ_{JA}=31°C/W, θ_{JC}=1.1°C/W; 68-pin ceramic LCC θ_{JA}=36°C/W, θ_{JC}=2.6°C/W.

[3]Measured with analog input = 0 V.

[4]See definitions of specifications.

[5]Outputs terminated through 100 Ω to −2.0 V; C_L<4 pF

[6]ENCODE command rise/fall times should be less than 2.5 ns for normal operation.

[7]Measured at 250 MSPS encode rate; analog return is tied to +1 V dc. (See text and diagrams.)

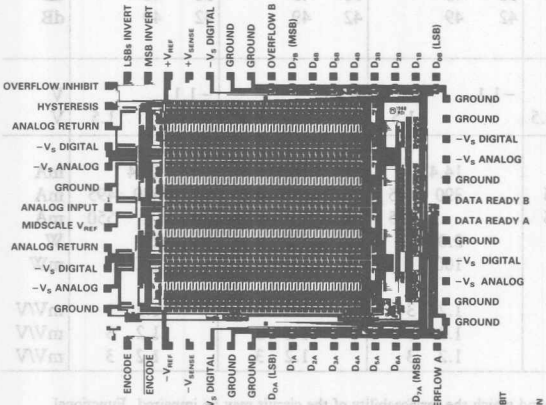
[8]RMS signal to rms noise with analog input signal 1 dB below full scale at specified frequency.

[9]Intermodulation measured with analog input frequencies of 60 MHz and 70 MHz at 7 dB below full scale.

Specifications subject to change without notice.

EXPLANATION OF TEST LEVELS

Test Level		
I	–	100% production tested.
II	–	100% production tested at +25°C, and sample tested at specified temperatures.
III	–	Sample tested only.
IV	–	Parameter is guaranteed by design and characterization testing.
V	–	Parameter is a typical value only.
VI	–	All devices are 100% production tested at +25°C. 100% production tested at temperature extremes for extended temperature devices; sample tested at temperature extremes for commercial/industrial devices.



RECOMMENDED OPERATING CONDITIONS

Parameter	Input Voltage Min	Nominal	Max
$-V_S$	−5.46	−5.2	−4.94
$+V_{REF}$	$-V_{REF}$	0	+0.1
$-V_{REF}$	−2.1	−2.0	$+V_{REF}$
ANALOG INPUT	$-V_{REF}$		$+V_{REF}$
ANALOG RETURN	Analog In		Analog In +2.0 V

AD9028/AD9038 Pin Designations
(Note: Chip Cavity Opening Is On Bottom of Package.)

AD9028/AD9038 PIN DESCRIPTIONS

Pin No.	Name	Function
1	ANALOG INPUT	Analog input is nominally between 0 and −2 Volts.
6, 66	ANALOG RETURN	Normally grounded; supplies current to input comparator circuits. Pins can be tied to postive potential (+2.0 V max), or buffered version of analog input to reduce capacitance and enhance dynamic performance. (See Applications.)
36	DATA READY A	Rising edge of signal can be used to externally latch D_{0A}–D_{7A}.
35	DATA READY B	Rising edge of signal can be used to externally latch D_{0B}–D_{7B}.
44–51	D_{7A}–D_{0A}	ECL digital data from Data Bank A.
20–27	D_{7B}–D_{0B}	ECL digital data from Data Bank B.
59, 60	ENCODE, ENCODE	Differential ECL convert signals.
3, 17, 18, 29, 30, 33, 38, 41, 42, 52, 53, 63	GROUND	All ground pins should be connected together.
8	HYSTERESIS	Normally grounded; hysteresis control pin.
10	LSBs INVERT	Normally connected to $-V_S$. When grounded, lower order bits are inverted.
67	MIDSCALE V_{REF}	Normally floating; midpoint of reference resistor ladder. Can be adjusted to minimize integral nonlinearity.
11	MSB INVERT	Normally connected to $-V_S$. When grounded, MSB is inverted.
43	OVERFLOW A	ECL-compatible output indicating ANALOG IN > $+V_{SENSE}$.
19	OVERFLOW B	ECL-compatible output indicating ANALOG IN > $+V_{SENSE}$.
9	OVERFLOW INHIBIT	Normally floating or tied to $-V_S$. When grounded, OVERFLOW A and B are disabled; D0–D7 remain at ECL logic "1" when ANALOG IN > $+V_{SENSE}$.
13	$+V_{REF}$	Normally 0 V; sets voltage reference at top of ladder.
57	$-V_{REF}$	Normally −2 V; sets voltage reference at bottom of ladder.
4, 32, 40, 64	$-V_S$ ANALOG	−5.2 Volts; analog supply voltage.
5, 16, 31, 39, 54, 65	$-V_S$ DIGITAL	−5.2 Volts; digital supply voltage.
14	$+V_{SENSE}$	Voltage sense line to most positive comparator reference input.
56	$-V_{SENSE}$	Voltage sense line to most negative comparator reference input.

DEFINITIONS OF SPECIFICATIONS

Analog Bandwidth
The analog input frequency at which the spectral power of the fundamental frequency (as determined by FFT analysis) is reduced by 3 dB.

Aperture Delay
The delay between the rising edge of the ENCODE command and the instant at which the analog input is sampled.

Aperture Uncertainty (Jitter)
The sample-to-sample variation in aperture delay.

Data Ready Output Delay
The delay between the 50% point of the falling edge of the ENCODE command and the 50% point of the rising edge of DATA READY A or DATA READY B.

Differential Nonlinearity
The deviation of any code from an ideal 1 LSB step.

Effective Number of Bits (ENOB)
ENOB is a measure of ac linearity and is calculated from a sine wave curve fit according to the following expression:

$$ENOB = N - LOG_2 [\text{ rms error (actual)/rms error (ideal) }]$$

N is the resolution (number of bits) of the converter. The actual rms error is the deviation from an ideal sine wave, calculated from the converter outputs with a sine wave input.

In-Band Harmonics
The rms value of the fundamental divided by the rms value of the worst harmonic.

Integral Nonlinearity
The deviation of the transfer function from a reference line measured in fractions of 1 LSB using a "best straight line" determined by a least square curve fit.

Maximum Conversion Rate
The encode rate at which the SNR of the lowest analog signal frequency tested drops by no more than 3 dB below the guaranteed limit.

Output Delay
The delay between the 50% point of the rising edge of the ENCODE command and the 50% point of output data.

Output Time Skew
Bit-to-bit time variations among D0 to D7 outputs. In the AD9028 and AD9038 specifications, time skew includes HIGH-to-LOW and LOW-to-HIGH transitions of the digital output bits.

Overvoltage Recovery Time
The amount of time required for the converter to recover to 8-bit accuracy after an analog input signal 150% of full scale is reduced to the full scale (0 to −2 V) range of the converter.

Power Supply Rejection Ratio
The ratio of a change in input offset voltage to a change in power supply voltage. In the AD9028 and AD9038 units, $-V_S$ (−5.2 V) is within ±5% of its nominal value for this test.

DEFINITIONS OF SPECIFICATIONS (continued)

Reference Ladder Offset
The deviation between the top (or bottom) comparator transition voltage as measured at the analog input, and the voltage at the $+V_{REF}$ (or $-V_{REF}$) pin. This is valuable in determining the accuracy and adjustment range for $\pm V_{REF}$ sources.

Signal-to-Noise Ratio (SNR)
The ratio of the rms signal amplitude to the rms value of "noise," which is defined as the sum of all other spectral components, including harmonics but excluding dc, with an analog input signal 1 dB below full scale.

Transient Response
The time required for the converter to achieve 8-bit accuracy when a step function is applied to the analog input.

Two-Tone Intermodulation Distortion (IMD) Rejection
The ratio of the power of either of two input signals to the power of the strongest third-order IMD signal.

THEORY OF OPERATION

Refer to the AD9038 Block Diagram. Both units use a "flash," or parallel, A/D architecture. The analog input voltage range is determined by an external voltage reference ($+V_{REF}$ and $-V_{REF}$), nominally 0 to −2 V. An internal resistor ladder divides this reference into 255 levels, each representing a single quantization level.

The A/D conversion, triggered by the ENCODE signal, is performed by 255 comparators. The output of the comparators indicates the appropriate quantization level of the analog input signal. The decoding logic processes the comparator outputs and provides an 8-bit code to the output stage.

Flash architecture has an advantage over other A/D architectures because the conversion occurs in one step, and the performance of the converter is limited primarily by the speed and matching of the individual comparators. A state-of-the-art bipolar process and careful comparator design give the AD9028/AD9038 excellent ac performance. A proprietary decoding scheme minimizes error codes, and control pins allow the user to select among Binary, Inverted Binary, Twos Complement and Inverted Twos Complement coding.

APPLICATIONS

Voltage References
The AD9028/AD9038 requires that the user provide two voltage references: $+V_{REF}$ and $-V_{REF}$, as shown in Figure 1. These two voltages are applied across an internal resistor ladder (nominally 40 Ω) and set the analog input voltage range of the converter. Each voltage reference should be driven from a stable, low impedance source. The reference connections should be capacitively coupled to ground to bypass noise.

Applying a voltage greater than 2.1 V across the internal resistor ladder will cause current densities to exceed rated values, and may cause permanent damage to the AD9028/AD9038. The design of the reference circuit should limit the voltage available to the references.

Resistance between the reference connections and the taps of the first and last comparators causes offset errors. These errors, called "top and bottom of the ladder offsets," can be nulled by using the voltage sense lines, $+V_{SENSE}$ and $-V_{SENSE}$, to adjust the reference voltages. Current through the sense lines should be limited to 100 μA.

The voltage at the midpoint of the resistor ladder, MIDSCALE VREF, can be adjusted to improve the integral linearity of individual devices.

A suggested application in Figure 4 shows a reference circuit which nulls out the offset errors using two op amps. Feedback from the sense lines causes the op amps to compensate for the offset errors. The two transistors limit the amount of current drawn directly from the op amp; resistors at the base and emitter stabilize their operation.

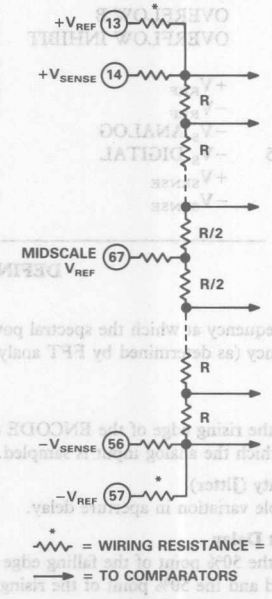

Figure 1. Reference Ladder

Analog Input Signal
The analog input circuit of the AD9028/AD9038 consists of 255 comparator inputs and can be represented by a single transistor as shown in Figure 2.

Typically, the ANALOG INPUT has an input resistance of 100 kΩ. Input capacitance is characterized in Figure 3.

With ANALOG RETURN (collector of the input transistor) connected to ground, collector base capacitance causes the analog input capacitance to be dependent on the analog input voltage. This varying capacitance is typical of flash converters, and requires that the ANALOG INPUT be driven from a low impedance source. This source must be capable of driving a capacitive load to avoid distorting the analog input signal at high

frequencies. In applications where the analog source cannot adequately drive the input capacitance, harmonic distortion will increase; the effect will be greatest on the second harmonic.

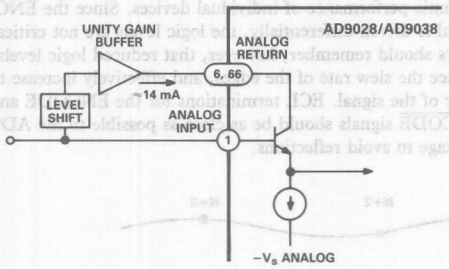

Figure 2. Preferred Analog Input Configuration

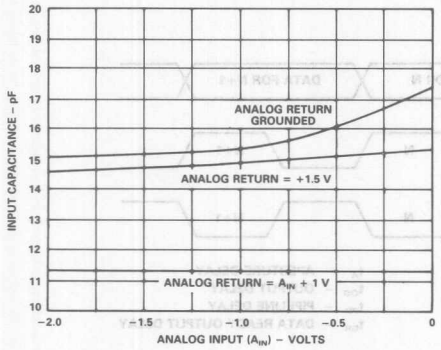

Figure 3. Input Capacitance vs. Input Voltage

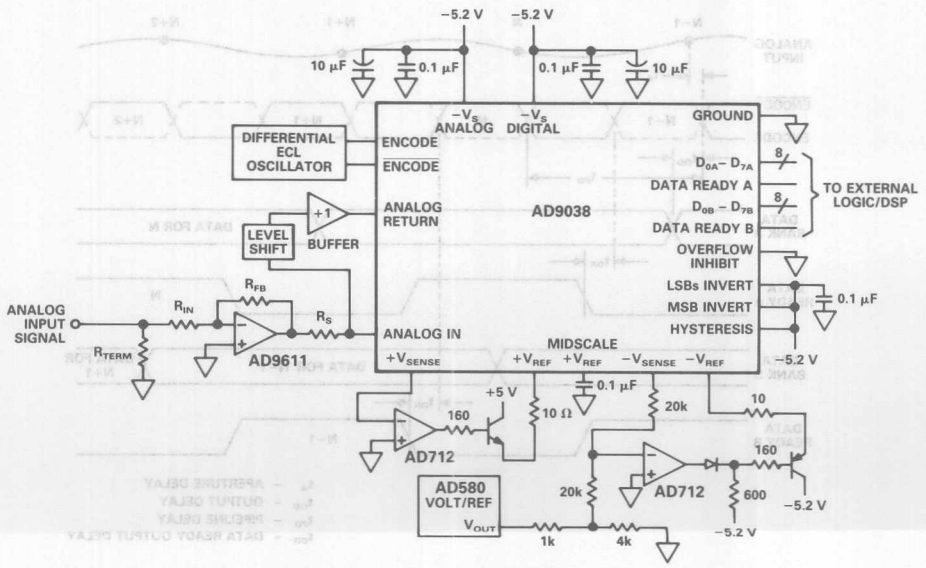
AC performance of the AD9028/AD9038 can be improved by connecting the ANALOG RETURN to a dc voltage between ground and +1.5 V. This reduces the analog input capacitance and lessens its dependence on the analog input voltage (see Figure 3).

The circuits shown in Figure 2 and Figure 4 show the ANALOG RETURN driven by a buffered version of the signal presented to the ANALOG INPUT. The dc level of this signal is 1 V higher than the analog input, and thus reduces the analog input capacitance as described above. In addition, the signal cancels the ac voltage between the ANALOG RETURN and ANALOG INPUT connections, which minimizes the collector-base component of the analog input capacitance. The analog input capacitance characteristics under this condition are also shown in Figure 3.

In any of the configurations described above, the user should drive the analog signal from a low distortion, low noise amplifier. A good choice is the AD9611, a wide bandwidth operational amplifier with excellent ac performance.

Selection of the buffer is also important for applications in which the analog input signal is applied to the ANALOG RETURN. The gain of the buffer should be set as close to 1 as possible, and the buffer should have a low phase shift at the frequencies of interest. It must also be able to supply the current required, typically 14 mA.

Harmonic distortion at the ANALOG RETURN is not as critical as that at the ANALOG INPUT, but should remain less than 40 dB (out to 100 MHz) to maximize converter performance. The input impedance at this node is approximately 6.5 kΩ in parallel with 25 pF. Monolithic wideband operational amplifiers and closed loop buffers should be suitable for driving this input.



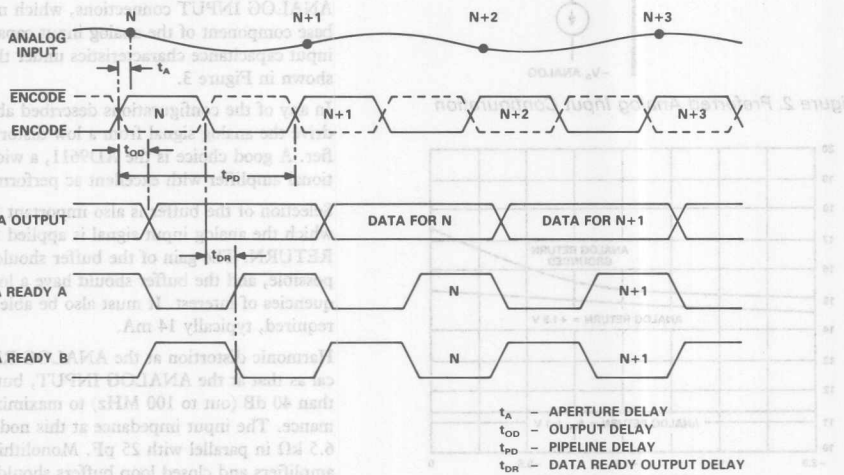


Figure 4. AD9038 Typical Application

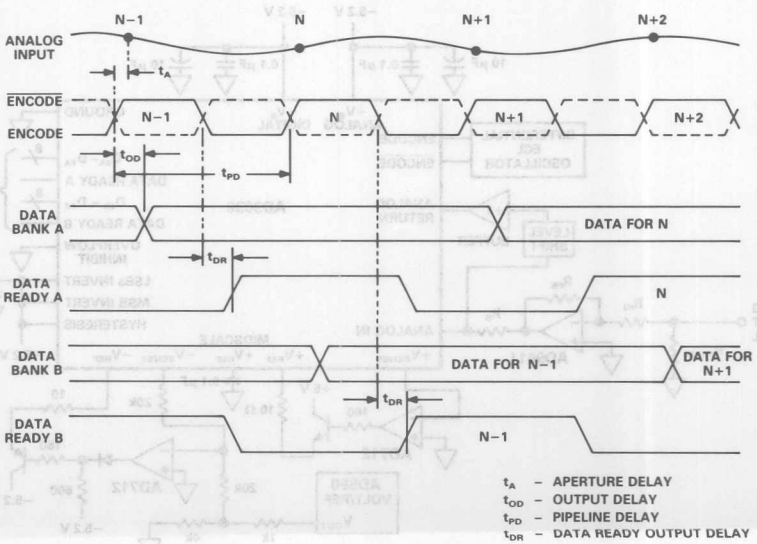


the A/D conversion by latching the comparators. The falling edge of the ENCODE signal returns the comparators to track mode and triggers the Data Ready signal.

ENCODE and $\overline{\text{ENCODE}}$ are ECL compatible and should be driven differentially. Jitter on the ENCODE signal will raise the noise floor of the converter. Differential signals, with fast clean edges, will reduce the jitter in the signal and allow optimum ac performance. In applications with a fixed, high frequency reduced) by using a crystal oscillator as the system clock.

The AD9028 is designed to operate with a 50% duty cycle ENCODE signal; adjustment of the duty cycle may improve the dynamic performance of individual devices. Since the ENCODE signal is driven differentially, the logic levels are not critical. Users should remember, however, that reduced logic levels will reduce the slew rate of the edges, and effectively increase the jitter of the signal. ECL terminations for the ENCODE and $\overline{\text{ENCODE}}$ signals should be as close as possible to the AD9028 package to avoid reflections.

AD9028 Timing Diagram

AD9038 Timing Diagram

Output data of the AD9028, D_{0A}–D_{7A} and OVERFLOW A, as well as the data ready signals, are also ECL compatible, and should be terminated through 100 Ω to −2 V (or an equivalent load). The output data can be latched on the rising edge of the DATA READY A output. For the AD9028, the DATA READY B output is simply the complement of DATA READY A.

Timing for the AD9038 is similar to the AD9028, except at the output, where the data is demultiplexed to two separate ports. Successive data samples alternate between the two ports, reducing the output data rate at either port to one-half the encode rate. Data at port A (D_{0A}–D_{7A} and OVERFLOW A) can be latched externally using the rising edge of DATA READY A. The rising edge of DATA READY B can be used to latch the data at port B (D_{0B}–D_{7B} and OVERFLOW B).

The data ready outputs for both the AD9028 and AD9038 are designed to track timing shifts over temperature.

Data Format

The format of the output data is controlled by the MSB INVERT and LSBs INVERT pins. These inputs are dc control inputs and should be connected to GROUND or $-V_S$. The AD9028/AD9038 Truth Table gives information to choose among Binary, Inverted Binary, Twos Complement and Inverted Twos Complement coding.

The OVERFLOW INHIBIT pin controls how the converter handles overflow situations (ANALOG INPUT > $+V_{SENSE}$). For normal operation, the OVERFLOW INHIBIT is connected to $-V_S$, and the output data bits (D_{0A}–D_{7A} or D_{0B}–D_{7B}) will be at a logic LOW when ANALOG INPUT > $+V_{SENSE}$ (return to zero operation). The overflow bit (OVERFLOW A or OVERFLOW B) will indicate this condition with a logic HIGH. When the ANALOG INPUT is in range (< $+V_{SENSE}$), the overflow bit will remain at logic LOW.

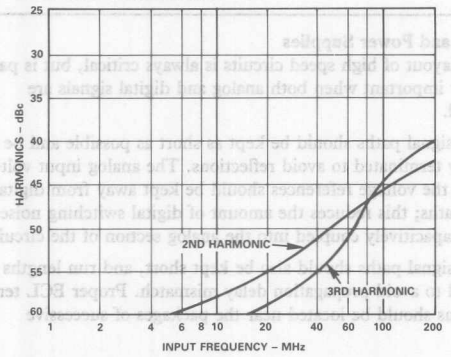
If the OVERFLOW INHIBIT pin is connected to ground, the overflow bit will be disabled, and the output data will remain at logic high for overflow conditions. The overflow bits are not affected by the bit invert control pins (MSB INVERT and LSBs INVERT).

Layout and Power Supplies

Proper layout of high speed circuits is always critical, but is particularly important when both analog and digital signals are involved.

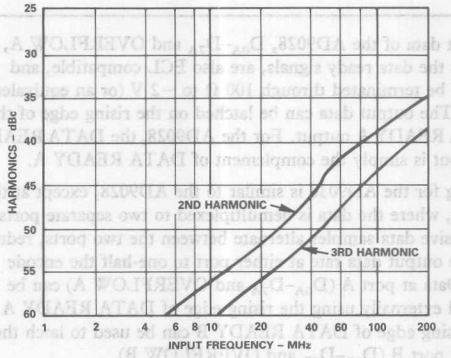
Analog signal paths should be kept as short as possible and be properly terminated to avoid reflections. The analog input voltage and the voltage references should be kept away from digital signal paths; this reduces the amount of digital switching noise that is capacitively coupled into the analog section of the circuit.

Digital signal paths should also be kept short, and run lengths matched to avoid propagation delay mismatch. Proper ECL terminations should be located near the packages of successive gates.



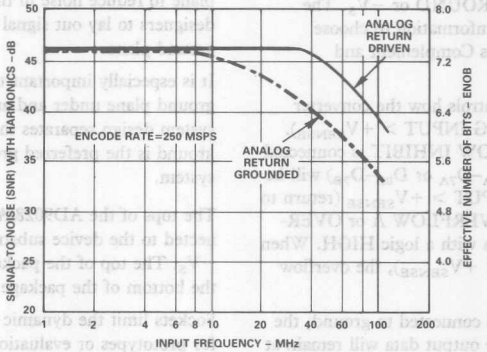
In high speed circuits, layout of the ground circuit is the most important factor. A single, low impedance ground plane, on the component side of the board, will reduce noise on the circuit ground.

Power supplies should be capacitively coupled to the ground plane to reduce noise in the circuit. Multilayer boards allow designers to lay out signal traces without interrupting the ground plane.



It is especially important to maintain the continuity of the ground plane under and around the AD9028/AD9038. If the system design separates the digital and analog grounds, analog ground is the preferred ground point for the A/D section of the system.

The tops of the AD9028/AD9038 packages are internally connected to the device substrates, and electrically connected to $-V_S$. The top of the package is designed to serve as a heat sink; the bottom of the package is not internally connected.



Sockets limit the dynamic performance and should be used only for prototypes or evaluation.

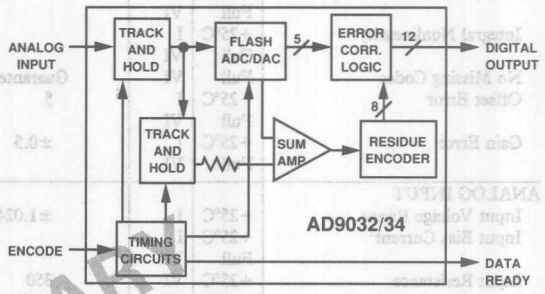
12-Bit, 25/20 MSPS A/D Converters

AD9032/AD9034



FEATURES

25 MSPS (AD9032), 20 MSPS (AD9034) Conversion Speeds
On-Board T/H, References, Timing
Low Power: 5 W
Single 40-Pin Package
70 dB Spurious-Free Dynamic Range to 10 MHz
Bipolar Input: ±1.024 V

APPLICATIONS

Radar
Signal Intelligence
Digital Spectrum Analyzers
Medical Imaging
Electro-Optics

FUNCTIONAL BLOCK DIAGRAM

PRELIMINARY TECHNICAL DATA

GENERAL DESCRIPTION

The AD9032 is the world's fastest (25 MSPS) complete 12-bit analog-to-digital converter (ADC), and features the latest in track-and-hold technology. The unit is a complete solution; on-board T/H, voltage references, and timing are all contained in a single 40-pin hybrid package. The pin-compatible AD9034 A/D converter operates at word rates of 20 MSPS.

This ECL-compatible ADC requires only +5 V and −5.2 V supplies, an analog input, and a stable ECL clock to obtain the best dynamic performance available in a 12-bit ADC.

Dynamic performance has been optimized to achieve SNR of 66 dB and a spurious-free dynamic range (SFDR) of 72 dB for analog bandwidths up to 10 MHz. All dynamic performance is guaranteed for sample rates from dc to 25.6 MSPS.

This information applies to a product under development. Its characteristics and specifications are subject to change without notice. Analog Devices assumes no obligation regarding future manufacture unless otherwise agreed to in writing.

[3]RMS signal to rms noise with analog input signal 1 dB below full scale at specified frequency.
[4]Intermodulation measured with analog input frequencies of 11 MHz and 12 MHz at 7 dB below full scale.
[5]PSRR is sensitivity of offset error to power supply variations within the 5% limits shown.
Specifications subject to change without notice.

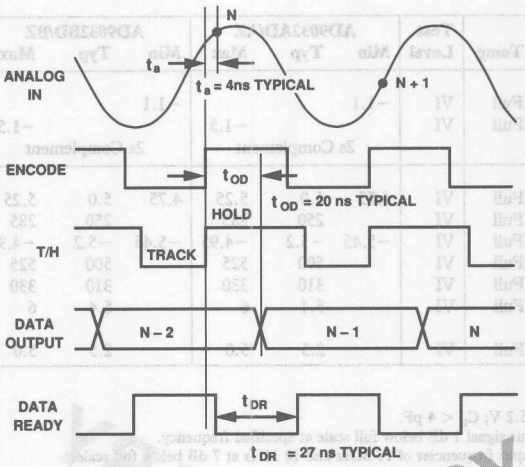
PRELIMINARY TECHNICAL DATA

ABSOLUTE MAXIMUM RATINGS[1]

$+V_S$ . . . . . +6 V
$-V_S$ . . . . . −6 V
Analog Input . . . . . $-V_S$ to $+V_S$
Digital Inputs . . . . . $-V_S$ to 0 V
Digital Output Current . . . . . 20 mA
Operating Temperature Range
AD9032AD/BD/AZ/BZ . . . . . −25°C to +85°C
AD9032TD/TZ . . . . . −55°C to +125°C
Maximum Junction Temperature[2] . . . . . +175°C
Lead Temperature (Soldering, 10 seconds) . . . . . +300°C
Storage Temperature Range . . . . . −65°C to +150°C

NOTES
[1]Absolute maximum ratings are limiting values to be applied individually, and beyond which the serviceability of the circuit may be impaired. Functional operability is not necessarily implied. Exposure to absolute maximum rating conditions for an extended period of time may affect device reliability.
[2]Typical thermal impedances: θ_{CA} = 12°C/W; T_J–T_C = 10°C max (worst case die junction temperature rise).

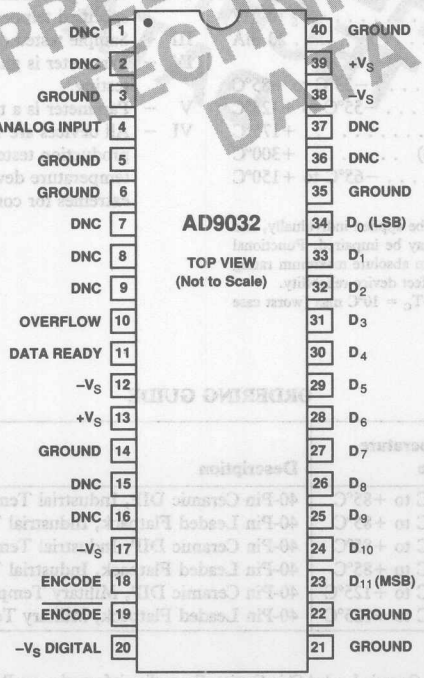
EXPLANATION OF TEST LEVELS



Test Level
I – 100% production tested.
II – 100% production tested at +25°C, and sample tested at specified temperatures. AC testing done on sample basis.
III – Sample tested only.
IV – Parameter is guaranteed by design and characterization testing.
V – Parameter is a typical value only.
VI – All devices are 100% production tested at +25°C. 100% production tested at temperature extremes for extended temperature devices; sample tested at temperature extremes for commercial/industrial devices.

ORDERING GUIDE

Model	Temperature Range	Description	Package Option[1]
AD9032AD	−25°C to +85°C	40-Pin Ceramic DIP, Industrial Temperature	D-40
AD9032AZ[2]	−25°C to +85°C	40-Pin Leaded Flatpack, Industrial Temperature	Z-40
AD9032BD	−25°C to +85°C	40-Pin Ceramic DIP, Industrial Temperature	D-40
AD9032BZ[2]	−25°C to +85°C	40-Pin Leaded Flatpack, Industrial Temperature	Z-40
AD9032TD	−55°C to +125°C	40-Pin Ceramic DIP, Military Temperature	D-40
AD9032TZ[2]	−55°C to +125°C	40-Pin Leaded Flatpack, Military Temperature	Z-40



NOTES
[1]D = Ceramic DIP; Z = Ceramic Leaded Chip Carrier. For outline information see Package Information section.
[2]Surface mount leaded packages are tested and shipped with unformed leads. Consult the factory for price and availability of packages with formed leads.

Advanced Television (MUSE Decoders)

FUNCTIONAL BLOCK DIAGRAM

GENERAL DESCRIPTION

The AD9040 is a complete 10-bit sampling analog-to-digital converter (ADC) with on-board track-and-hold. The unit is designed for low cost, high performance applications and requires only an encode signal to achieve 40 MSPS sample rates with 10-bit resolution.

Digital inputs and outputs are TTL/CMOS compatible. The analog input requires a signal of 2 V p–p amplitude and can be driven differentially. The two-step architecture used in the AD9040 is optimized to provide the best dynamic performance available while maintaining low power requirements.

NOTES
[1]Output delay measured as worst-case time from 50% point of the falling edge of ENCODE to 50% point of the slowest rising or falling edge of D0–D9. Output skew measured as worst-case difference in output delay among D0–D9.
[2]RMS signal to rms noise with analog input signal 1 dB below full scale at specified frequency.
[3]Intermodulation measured with analog input frequencies of 2.3 MHz and 3.0 MHz at 7 dB below full scale.
[4]For rated performance at 40 MSPS, duty cycle of encode command should be 50% ±5%.
[5]Measured as the ratio of the worst-case change in transition voltage of a single comparator for a 5% change in V_{CC} or V_{EE}.
Specifications subject to change without notice.

PRELIMINARY TECHNICAL DATA

ABSOLUTE MAXIMUM RATINGS[1]

$+V_S$ (V_{DD} and V_{CC}) . . . . . +7 V
$-V_S$ (V_{SS} and V_{EE}) . . . . . −7 V
Analog In . . . . . $-V_S$ to $+V_S$
Digital Inputs . . . . . 0 V to $+V_S$
Digital Output Current . . . . . 20 mA
Operating Temperature
AD9040JN/JP/KN/KP . . . . . 0°C to +70°C
AD9040TE/TQ . . . . . −55°C to +125°C
Storage Temperature . . . . . −65°C to +150°C
Maximum Junction Temperature[2] . . . . . +175°C
Lead Soldering Temp (10 sec) . . . . . +300°C

NOTES
[1]Absolute maximum ratings are limiting values to be applied individually, and beyond which the serviceability of the circuit may be impaired. Functional operability is not necessarily implied. Exposure to absolute maximum rating conditions for an extended period of time may affect device reliability.
[2]Typical thermal impedances: "N" Package (Plastic DIP): θ_{JC} = 7°C/W; θ_{JA} = 42°C/W; "P" Package (PLCC): θ_{JC} = 10°C/W; θ_{JA} = 48°C/W; "E" Package (Ceramic LCC): θ_{JC} = 23°C/W; θ_{JA} = 69°C/W; "Q" Package (Ceramic DIP): θ_{JC} = 25°C/W; θ_{JA} = 75°C/W.

This information applies to a product under development. Its characteristics and specifications are subject to change without notice. Analog Devices assumes no obligation regarding future manufacture unless otherwise agreed to in writing.

Monolithic 8-Bit Video A/D Converter

AD9048

FEATURES
- 35MSPS Encode Rate
- 16pF Input Capacitance
- 550mW Power Dissipation
- Industry-Standard Pinouts
- MIL-STD-883 Compliant Versions Available

APPLICATIONS
- Professional Video Systems
- Special Effects Generators
- Electro-Optics
- Digital Radio
- Electronic Warfare (ECM, ECCM, ESM)

FUNCTIONAL BLOCK DIAGRAM

GENERAL DESCRIPTION

The AD9048 is an 8-bit, 35MSPS flash converter, made on a high speed bipolar process, which is an alternate source for the TDC1048 unit but offers enhancements over its predecessor. Lower power dissipation makes the AD9048 attractive for a variety of system designs.

Because of its wide bandwidth, it is an ideal choice for real-time conversion of video signals. Input bandwidth is flat with no missing codes.

Clocked latching comparators, encoding logic and output buffer registers operating at minimum rates of 35MSPS preclude a need for a sample-and-hold (S/H) or track-and-hold (T/H) in most system designs using the AD9048. All digital control inputs and outputs are TTL compatible.

Devices operating over two ambient temperature ranges and with two grades of linearity are available. Linearities of either 0.5LSB or 0.75LSB can be ordered for a commercial range of 0 to +70°C, or extended case temperatures of −55°C to +125°C. Commercial versions are packaged in 28-pin DIPs; extended temperature versions are available in ceramic DIP and ceramic LCC packages. Both commercial units and MIL-STD-883 units are standard products.

The AD9048 A/D converter is available in versions compliant with MIL-STD-883. Refer to the Analog Devices *Military Products Databook* or current AD9048/883B data sheet for detailed specifications.

AGND to DGND . . . . . −0.5V dc to +0.5V dc
V_{EE} to AGND . . . . . +0.5V dc to −7.0V dc
V_{IN}, V_{RT} or V_{RB} to AGND . . . . . +0.5V to V_{EE}
V_{RT} to V_{RB} . . . . . −2.2V dc to +2.2V dc
CONV, NMINV or NLINV to DGND . −0.5V dc to +5.5V dc
Applied Output Voltage to DGND . −0.5V dc to +5.5V dc[2]
Applied Output Current, Externally Forced
. . . . . −1.0mA to +6.0mA[3, 4]

Operating Temperature Range (Ambient)
AD9048JN/KN/JJ/KJ/JQ/KQ . . . . . 0 to +70°C
AD9048SE/SQ/TE/TQ . . . . . −55°C to +125°C
Maximum Junction Temperature (Plastic) . . . . . +150°C[6]
Maximum Junction Temperature (Hermetic) . . . . . +175°C[6]
Lead Temperature (Soldering, 10sec) . . . . . +300°C
Storage Temperature Range . . . . . −65°C to +150°C

ELECTRICAL CHARACTERISTICS (V_{CC} = +5.0V; V_{EE} = −5.2V; Differential Reference Voltage = 2.0V, unless otherwise noted)

NOTES:

[1]Maximum ratings are limiting values, to be applied individually, and beyond which the serviceability of the device may be impaired. Functional operation under any of these conditions is not necessarily implied. Exposure to absolute maximum rating conditions for extended periods of time may affect device reliability.

[2]Applied voltage must be current-limited to specified range.

[3]Forcing voltage must be limited to specified range.

[4]Current is specified as negative when flowing into the device.

[5]Output High; one pin to ground; one second duration.

[6]Typical thermal impedances (no air flow) are as follows:

Ceramic DIP: θ_{JA} = 49°C/W; θ_{JC} = 15°C/W LCC: θ_{JA} = 69°C/W; θ_{JC} = 21°C/W

Plastic DIP: θ_{JA} = 58°C/W; θ_{JC} = 16°C/W PLCC: θ_{JA} = 59; θ_{JC} = 19

To calculate junction temperature (T_J), use power dissipation (PD) and thermal impedance:

$T_J = PD(\theta_{JA}) + T_{AMBIENT} = PD(\theta_{JC}) = + T_{CASE}$

[7]Measured with V_{IN} = 0V and CONVERT low (sampling mode).

[8]V_{CC} = +5.5V

[9]V_{EE} = −5.5V

[10]Determined by beat frequency testing for no missing codes.

[11]$V_{RT} \geq V_{RB}$ under all circumstances.

[12]V_{EE} = −4.9V

[13]Outputs terminated with 40pF and 810Ω pull-up resistors.

[14]V_{CC} = +4.5V

[15]Interval from 50% point of leading edge CONVERT pulse to change in output data.

[16]For full scale step input, 8-bit accuracy attained in specified time.

[17]Recovers to 8-bit accuracy in specified time after −3V input overvoltage.

[18]Output time skew includes high-to-low and low-to-high transitions as well as bit-to-bit time skew differences.

[19]Measured at 20MHz encode rate with analog input 1dB below full scale.

[20]Measured at 35MHz encode rate with analog input 1dB below full scale.

[21]RMS signal to rms noise.

[22]Peak signal to rms noise.

[23]DC to 8MHz noise bandwidth with 1.248MHz slot; four sigma loading; 20MHz encode.

[24]Clock frequency = 4 × NTSC = 14.32MHz. Measured with 40-IRE modulated ramp.

Specifications subject to change without notice.

EXPLANATION OF TEST LEVELS

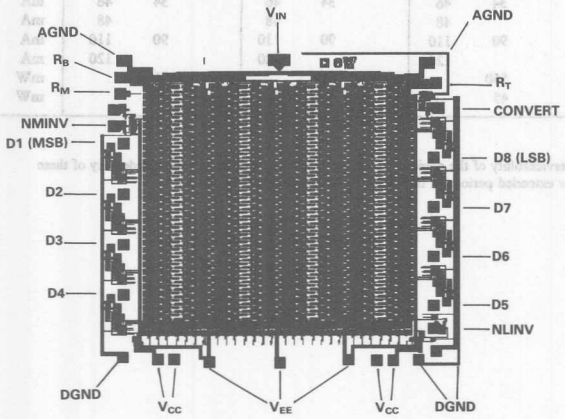
Test Level I – 100% production tested.

Test Level II – 100% production tested at +25°C and sample tested at specified temperatures.

Test Level III – Sample tested only.

Test Level IV – Parameter is guaranteed by design and characterization testing.

Test Level V – Parameter is a typical value only.



Test Level VI – All devices are 100% production tested at 25°C. 100% production tested at temperature extremes for military temperature devices; sample tested at temperature extremes for commercial/industrial devices.

ORDERING GUIDE

Model	Linearity	Temperature	Package Option[1]
AD9048JN	0.75LSB	0 to +70°C	N-28

FUNCTIONAL DESCRIPTION

Pin Name	Description
D1 – D8	Eight digital outputs. D1 (MSB) is the most significant bit of the digital output word; D8 (LSB) is the least significant bit.
AGND	One of two analog ground returns. Both grounds should be connected together and to low impedance ground plane near the AD9048.
DGND	One of two digital ground returns. Both grounds should be connected together and to low impedance ground plane near the AD9048.
V_{CC}	Positive supply terminals; nominally +5.0V.
V_{EE}	Negative supply terminals; nominally −5.2V.
CONVERT	Input for conversion signal; sample of analog input signal taken on rising edge of this pulse.
R_B	Most negative reference voltage for internal reference ladder.
R_M	Midpoint tap on internal reference ladder.
R_T	Most positive reference voltage for internal reference ladder.
V_{IN}	Analog input signal pin.
NMINV	"Not Most Significant Bit Invert." In normal operation, this pin floats high; logic LOW at NMINV inverts most significant bit of digital output word [D1 (MSB)].
NLINV	"Not Least Significant Bit Invert." In normal operation, this pin floats high; logic LOW at NLINV inverts the seven least significant bits of the digital output word.

AD9048 Burn-In Diagram

THEORY OF OPERATION

Refer to the block diagram of the AD9048. The AD9048 comprises three functional sections: a comparator array, encoding logic, and output latches.

Within the array, the analog input signal to be digitized is compared with 255 reference voltages. The outputs of all comparators whose references are below the input signal level will be high; and outputs whose references are above that level will be low.

The n-of-255 code which results from this comparison is applied to the encoding logic where it is converted into binary coding. When it is inverted with dc signals applied to the NLINV and/or NMINV pins, it becomes twos complement.

After encoding, the signal is applied to the output latch circuits where it is held constant between updates controlled by the application of CONVERT pulses.

The AD9048 uses strobed latching comparators in which comparator outputs are either high or low, as dictated by the analog input level. Data appearing at the output pins have a pipeline delay of one encode cycle.

Input signal levels between the references applied to R_T (Pin 18) and R_B (Pin 26) will appear at the output as binary numbers between 0 and 255, inclusive. Signals outside that range will show up as either full-scale positive or full-scale negative outputs. No damage will occur to the AD9048 as long as the input is within the voltage range of V_{EE} to +0.5V.

The significantly reduced input capacitance of the AD9048 lowers the drive requirements of the input buffer/amplifier and also induces much smaller phase shift in the analog input signal.

Applications which depend on controlled phase shift at the converter input can benefit from using the AD9048 because of its inherently lower phase shift.

The CONVERT, analog input and digital output circuits are shown in Figure 1, AD9048 Input/Output Circuits.

System timing which provides details on delays through the AD9048, as well as the relationships of various timing events, is shown in Figure 2, AD9048 Timing Diagram.

Dynamic performance of the AD9048, i.e., typical signal-to-noise ratio, is illustrated in Figures 3 and 4.

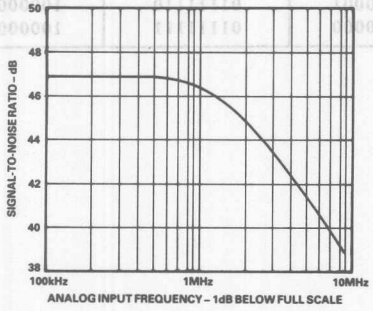

Figure 4. AD9048 Dynamic Performance (35MHz Encode Rate)

LAYOUT SUGGESTIONS

Designs which use the AD9048 or any other high-speed device must follow some basic layout rules to insure optimum performance.

The first requirement is to have a large, low impedance ground plane under and around the converter. If the system uses separate analog and digital grounds, both should be connected solidly together and to the ground plane as close to the AD9048 as practical, to avoid ground loop currents.

Ceramic 0.1μF decoupling capacitors should be placed as close as possible to the supply pins of the AD9048. For decoupling low frequency signals, use 10μF tantalum capacitors, also connected as close as practical to voltage supply pins.

Within the AD9048, reference currents may vary because of coupling between the clock and input signals. Because of this, it is important that the ends of the reference ladder, R_T (Pin 18) and R_B (Pin 28), be connected to low impedances (as measured from ground).

If the AD9048 is being used in a circuit in which the reference is not varied, a bypass capacitor to ground is strongly recommended. In applications which use varying references, they must be driven from a low impedance source.

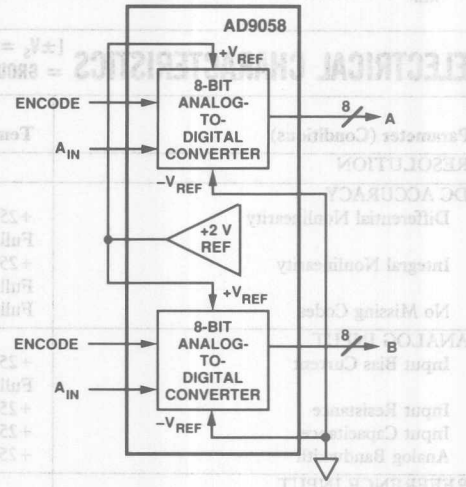
Dual 8-Bit, 50 MSPS A/D Converter

AD9058

FEATURES
Two Matched ADCs on Single Chip
50 MSPS Conversion Speed
On-Board Voltage Reference
Low Power (<1W)
Low Input Capacitance (10 pF)
±5 V Power Supplies
Flexible Input Range

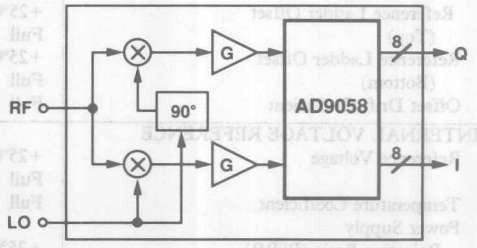
APPLICATIONS
Quadrature Demodulation for Communications
Digital Oscilloscopes
Electronic Warfare
Radar

GENERAL DESCRIPTION



The AD9058 combines two independent high performance 8-bit analog-to-digital converters (ADCs) on a single monolithic IC. Combined with an optional on-board voltage reference, the AD9058 provides a cost effective alternative for systems requiring two or more ADCs.

Dynamic performance (SNR, ENOB) is optimized to provide up to 50 MSPS conversion rates. The unique architecture results in low input capacitance while maintaining high performance and low power (<0.5 watt/channel). Digital inputs and outputs are TTL compatible.



Performance has been optimized for an analog input of 2 V p–p (±1 V; 0 to +2 V). Using the on-board +2 V voltage reference, the AD9058 can be set up for unipolar positive operation (0 to +2 V). This internal voltage reference can drive both ADCs.

Commercial (0°C to +70°C) and military (−55°C to +125°C) temperature range parts are available. Parts are supplied in hermetic 48-pin DIP and 44-pin "J" lead packages.

NOTES

[1]Absolute maximum ratings are limiting values to be applied individually, and beyond which the serviceability of the circuit may be impaired. Functional operability is not necessarily implied. Exposure to absolute maximum rating conditions for an extended period of time may affect device reliability.

[2]For applications in which $+V_S$ may be applied before $-V_S$, or $+V_S$ current is not limited to 500 mA, a reverse biased clamping diode should be inserted between ground and $-V_S$ to prevent destructive latch up. See section entitled "Using the AD9058."

[3]Typical thermal impedances: 44-pin hermetic J-Leaded ceramic package: θ_{JA} = 86.4°C/W; θ_{JC} = 24.9°C/W; 48-pin hermetic DIP θ_{JA} = 40°C/W; θ_{JC} = 12°C/W.

[4]To achieve guaranteed conversion rate, connect each data output to ground through a 2 kΩ pull-down resistor.

[5]SNR performance limits for the 48-pin DIP "D" package are 1 dB less than shown. ENOB limits are degraded by 0.3 dB. SNR and ENOB measured with analog input signal 1 dB below full scale at specified frequency.

[6]Crosstalk rejection measured with full-scale signals of different frequencies (2.3 MHz and 3.5 MHz) applied to each channel. With both signals synchronously encoded at 40 MSPS, isolation of the undesired frequency is measured with an FFT.

[7]Applies to both A/Ds and includes internal ladder dissipation.

Specifications subject to change without notice.

EXPLANATION OF TEST LEVELS

Test Level

I – 100% production tested.

II – 100% production tested at +25°C, and sample tested at specified temperatures.

III – Sample tested only.

IV – Parameter is guaranteed by design and characterization testing.

V – Parameter is a typical value only.

VI – All devices are 100% production tested at +25°C. 100% production tested at temperature extremes for extended temperature devices; sample tested at temperature extremes for commercial/industrial devices.

AD9058 Burn-In Connections

THEORY OF OPERATION

The AD9058 contains two separate 8-bit analog-to-digital converters (ADCs) on a single silicon die. The two devices can be operated independently with separate analog inputs, voltage references, and clocks.

In a traditional flash converter, 256 input comparators are required to make the parallel conversion for 8-bit resolution. This is in marked contrast to the scheme used in the AD9058, as shown in Figure 1.

Unlike traditional "flash," or parallel, converters, each of the two ADCs in the AD9058 utilizes a patented interpolating architecture to reduce circuit complexity, die size, and input capacitance. These advantages accrue because, compared to a conventional flash design, only half the normal number of input comparator cells is required to accomplish the conversion.

In this unit, each of the two independent ADCs uses only 128 (2^7) comparators to make the conversion. The conversion for the seven most significant bits (MSBs) is performed by the 128 comparators. The value of the least significant bit (LSB) is determined by interpolation between adjacent comparators in the decoding register. A proprietary decoding scheme processes the comparator outputs and provides an 8-bit code to the output register of each ADC; the scheme also minimizes error codes.

Analog input range is established by the voltages applied at the voltage reference inputs ($+V_{REF}$ and $-V_{REF}$). The AD9058 can operate from 0 V to +2 V using the internal voltage reference, or anywhere between −1 V and +2 V using external references. Input range is limited to 2 V p–p when using external references. The internal resistor ladder divides the applied voltage reference into 128 steps, with each step representing two 8-bit quantization levels.

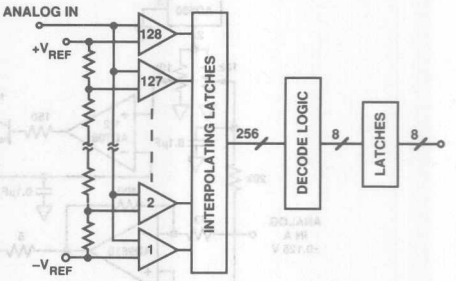

Figure 1. AD9058 Comparator Block Diagram

The on-board voltage reference, $+V_{INT}$, is a bandgap reference which has sufficient drive capability for both reference ladders. It provides a +2 V reference that can drive both ADCs in the AD9058 for unipolar positive operation (0 V to +2 V).

USING THE AD9058

Refer to Figure 2.

Using the internal voltage reference connected to both ADCs as shown reduces the number of external components required to create a complete data acquisition system. The input ranges of the ADCs are positive unipolar in this configuration, ranging from 0 V to +2 V. Bipolar input signals are buffered, amplified, and offset into the proper input range of the ADC using a good low distortion amplifier such as the AD9617 or AD9618.

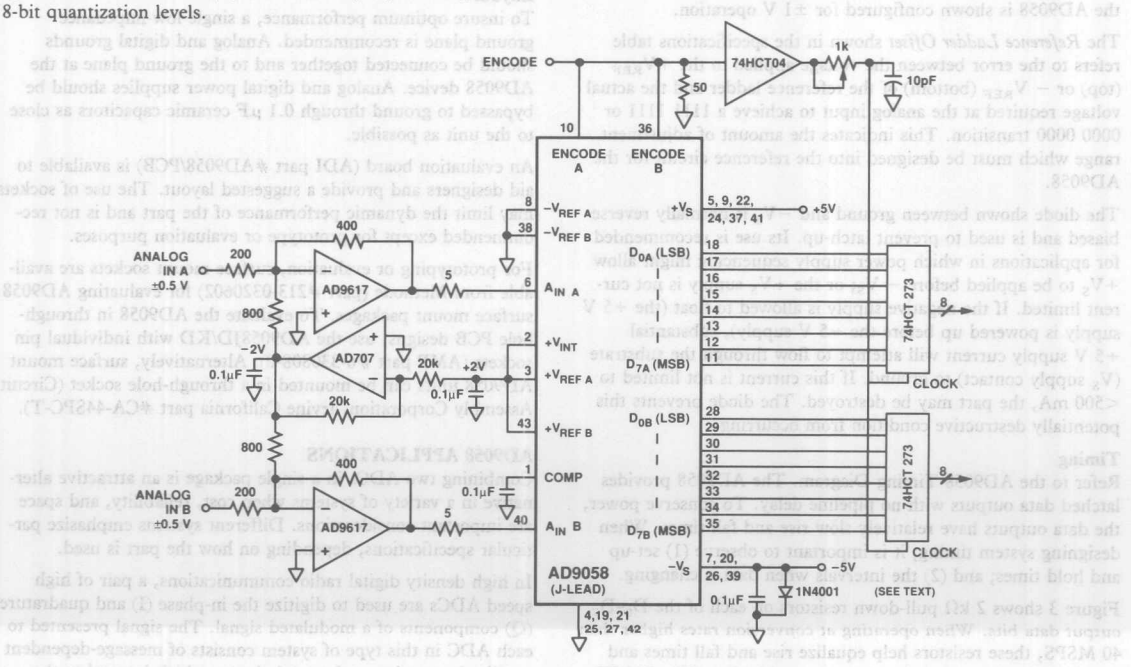

Figure 2. AD9058 Using Internal +2 V Voltage Reference

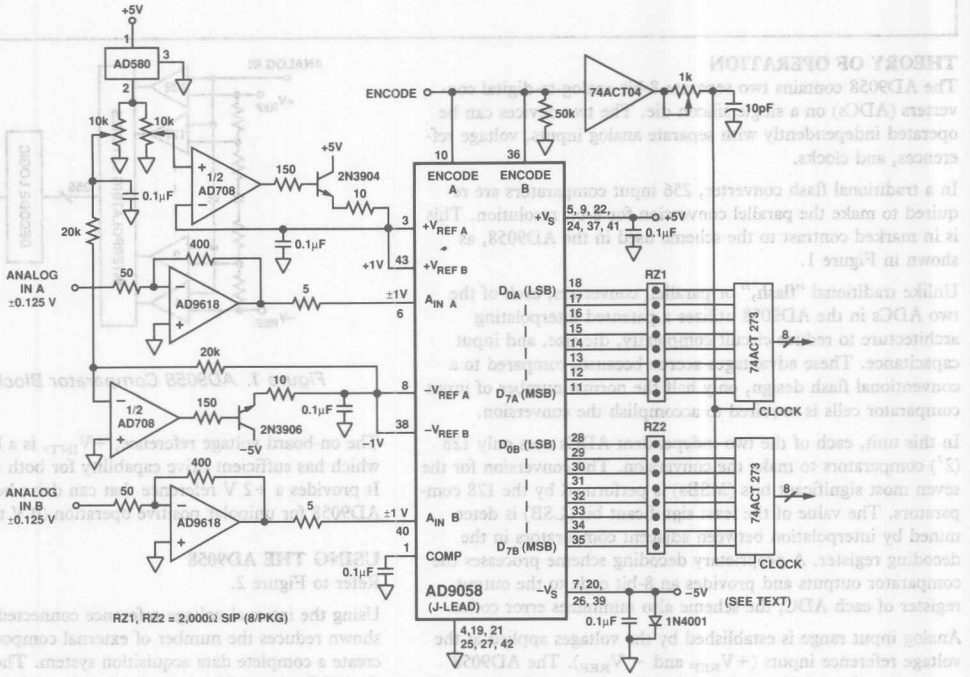

Figure 3. AD9058 Using External Voltage References

The AD9058 offers considerable flexibility in selecting the analog input ranges of the ADCs; the two independent ADCs can even have different input ranges if required. In Figure 3 above, the AD9058 is shown configured for ±1 V operation.

The *Reference Ladder Offset* shown in the specifications table refers to the error between the voltage applied to the $+V_{REF}$ (top) or $-V_{REF}$ (bottom) of the reference ladder and the actual voltage required at the analog input to achieve a 1111 1111 or 0000 0000 transition. This indicates the amount of adjustment range which must be designed into the reference circuit for the AD9058.

The diode shown between ground and $-V_S$ is normally reverse biased and is used to prevent latch-up. Its use is recommended for applications in which power supply sequencing might allow $+V_S$ to be applied before $-V_S$; or the $+V_S$ supply is not current limited. If the negative supply is allowed to float (the +5 V supply is powered up before the −5 V supply), substantial +5 V supply current will attempt to flow through the substrate (V_S supply contact) to ground. If this current is not limited to <500 mA, the part may be destroyed. The diode prevents this potentially destructive condition from occurring.

Timing

Refer to the AD9058 Timing Diagram. The AD9058 provides latched data outputs with no pipeline delay. To conserve power, the data outputs have relatively slow rise and fall times. When designing system timing, it is important to observe (1) set-up and hold times; and (2) the intervals when data is changing.

Figure 3 shows 2 kΩ pull-down resistors on each of the D_0–D_7 output data bits. When operating at conversion rates higher than 40 MSPS, these resistors help equalize rise and fall times and ease latching the output data into external latches. The 74ACT logic family devices have short set-up and hold times and are the recommended choices for speeds of 40 MSPS or more.

Layout

To insure optimum performance, a single low-impedance ground plane is recommended. Analog and digital grounds should be connected together and to the ground plane at the AD9058 device. Analog and digital power supplies should be bypassed to ground through 0.1 μF ceramic capacitors as close to the unit as possible.

An evaluation board (ADI part #AD9058/PCB) is available to aid designers and provide a suggested layout. The use of sockets may limit the dynamic performance of the part and is not recommended except for prototype or evaluation purposes.

For prototyping or evaluation, surface mount sockets are available from Methode (part #213-0320602) for evaluating AD9058 surface mount packages. To evaluate the AD9058 in through-hole PCB designs, use the AD9058JD/KD with individual pin sockets (AMP part #6-330808-0). Alternatively, surface mount AD9058 units can be mounted in a through-hole socket (Circuit Assembly Corporation, Irvine California part #CA-44SPC-T).

AD9058 APPLICATIONS

Combining two ADCs in a single package is an attractive alternative in a variety of systems when cost, reliability, and space are important considerations. Different systems emphasize particular specifications, depending on how the part is used.

In high density digital radio communications, a pair of high speed ADCs are used to digitize the in-phase (I) and quadrature (Q) components of a modulated signal. The signal presented to each ADC in this type of system consists of message-dependent amplitudes varying at the symbol rate, which is equal to the sample rates of the converters.

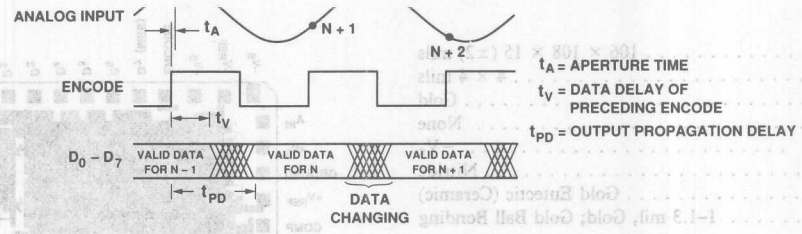

Figure 4. AD9058 Timing Diagram

Figure 5 below shows what the analog input to the AD9058 would look like when observed relative to the sample clock. Signal-to-noise ratio (SNR), transient response, and sample rate are all critical specifications in digitizing this "eye pattern."

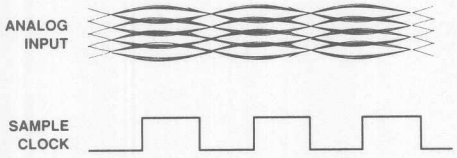

Figure 5. AD9058 I and Q Input Signals

Receiver sensitivity is limited by the SNR of the system. For the ADC, SNR is measured in the frequency domain and calculated with a Fast Fourier Transform (FFT). The *signal-to-noise ratio* equals the ratio of the fundamental component of the signal (rms amplitude) to the rms level of the noise. Noise is the sum of all other spectral components, including harmonic distortion, but excluding dc.

Although the signal being sampled does not have a significant slew rate at the instant it is encoded, dynamic performance of the ADC and the system is still critical. *Transient response* is the time required for the AD9058 to achieve full accuracy when a step function input is applied. *Overvoltage recovery time* is the interval required for the AD9058 to recover to full accuracy after an overdriven analog input signal is reduced to its input range.

Time domain performance of the ADC is also extremely important in digital oscilloscopes. When a track (sample)-and-hold is used ahead of the ADC, its operation becomes similar to that described above for receivers.

The dynamic response to high-frequency inputs can be described by the *effective number of bits* (ENOB). The *effective number of bits* is calculated with a sine wave curve fit and is expressed as:

$$ENOB = N - LOG_2 [Error\ (measured)/Error\ (ideal)]$$

where N is the resolution (number of bits) and measured error is actual rms error calculated from the converter's outputs with a pure sine wave applied as the input.

Maximum conversion rate is defined as the encode (sample) rate at which SNR of the lowest frequency analog test signal drops no more than 3 dB below the guaranteed limit.

FUNCTIONAL BLOCK DIAGRAM

GENERAL DESCRIPTION

The AD9060 A/D converter is a 10-bit monolithic converter capable of word rates of 75 MSPS and above. Innovative architecture using 512 input comparators instead of the traditional 1024 required by other flash converters reduces input capacitance and improves linearity.

Inputs and outputs are ECL-compatible, which makes the AD9060 the recommended choice for systems with conversion rates >30 MSPS, to minimize system noise. An overflow bit is provided to indicate analog input signals greater than $+V_{SENSE}$.

Voltage sense lines are provided to insure accurate driving of the $\pm V_{REF}$ voltages applied to the units. Quarter-point taps on the resistor ladder help optimize the integral linearity of the unit.

Either 68-pin ceramic leaded (gull wing) packages or ceramic LCCs are available and are specifically designed for low thermal impedances. Two performance grades for temperatures of both 0 to +70°C and −55°C to +125°C ranges are offered to allow the user to select the linearity best suited for each application. Dynamic performance is fully characterized and production tested at +25°C. MIL-STD-883 units are available.

The AD9060 A/D converter is available in versions compliant with MIL-STD-883. Refer to the Analog Devices *Military Products Databook* or current AD9060/883B data sheet for detailed specifications.

AD9060—SPECIFICATIONS

ABSOLUTE MAXIMUM RATINGS[1]

$+V_S$	+6 V
$-V_S$	−6 V
ANALOG IN	−2 V to +2 V
$+V_{REF}$, $-V_{REF}$, $3/4_{REF}$, $1/2_{REF}$, $1/4_{REF}$	−2 V to +2 V
$+V_{REF}$ to $-V_{REF}$	4.0 V
ENCODE, $\overline{\text{ENCODE}}$	0 V to $-V_S$
$3/4_{REF}$, $1/2_{REF}$, $1/4_{REF}$ Current	±10 mA
Digital Output Current	20 mA
Operating Temperature	
AD9060JE/KE/JZ/KZ	0 to +70°C
Storage Temperature	−65°C to +150°C
Maximum Junction Temperature[2]	+175°C
Lead Soldering Temp (10 sec)	+300°C

ELECTRICAL CHARACTERISTICS ($+V_S$ = +5 V; $-V_S$ = −5.2 V; $\pm V_{SENSE}$ = ±1.75 V; ENCODE = 60 MSPS unless otherwise noted)[3]

NOTES

[1]Absolute maximum ratings are limiting values to be applied individually, and beyond which the serviceability of the circuit may be impaired. Functional operability is not necessarily implied. Exposure to absolute maximum rating conditions for an extended period of time may affect device reliability.

[2]Typical thermal impedances (part soldered onto board): 68-pin leaded ceramic chip carrier: θ_{JC} = 1°C/W; θ_{JA} = 17°C/W (no air flow); θ_{JA} = 15°C/W (air flow = 500 LFM). 68-pin ceramic LCC: θ_{JC} = 2.6°C/W; θ_{JA} = 15°C/W (no air flow); θ_{JA} = 13°C/W (air flow = 500 LFM).

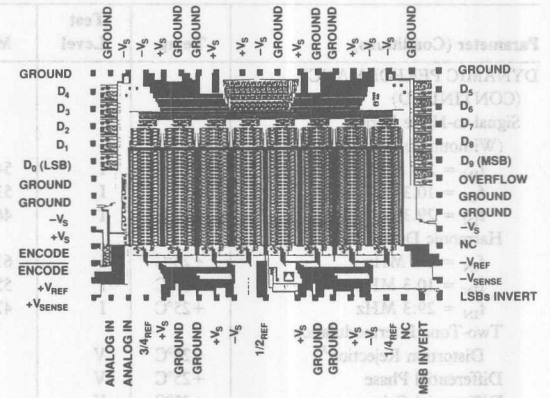
[3]$3/4_{REF}$, $1/2_{REF}$, and $1/4_{REF}$ reference ladder taps are driven from dc sources at +0.875 V, 0 V, and −0.875 V, respectively. Outputs terminated through 100 Ω to −2.0 V; C_L < 4 pF. Accuracy of the overflow comparator is not tested and not included in linearity specifications.

[4]Measured with ANALOG IN = $+V_{SENSE}$.

[5]Output delay measured as worst-case time from 50% point of the rising edge of ENCODE to 50% point of the slowest rising or falling edge of D_0–D_9. Output skew measured as worst-case difference in output delay among D_0–D_9.

[6]RMS signal to rms noise with analog input signal 1 dB below full scale at specified frequency.

[7]Intermodulation measured with analog input frequencies of 2.3 MHz and 3.0 MHz at 7 dB below full scale.



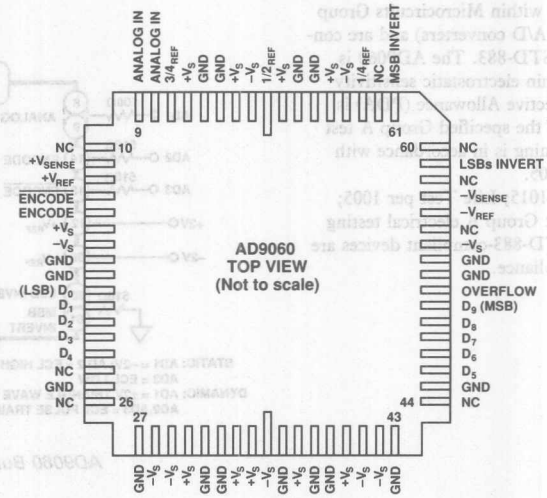
[8]Measured as the ratio of the worst-case change in transition voltage of a single comparator for a 5% change in $+V_S$ or $-V_S$.

Specifications subject to change without notice.

EXPLANATION OF TEST LEVELS

Test Level

I – 100% production tested.
II – 100% production tested at +25°C, and sample tested at specified temperatures.
III – Sample tested only.
IV – Parameter is guaranteed by design and characterization testing.
V – Parameter is a typical value only.
VI – All devices are 100% production tested at +25°C. 100% production tested at temperature extremes for extended temperature devices; sample tested at temperature extremes for commercial/industrial devices.



ORDERING GUIDE

Device	Temperature Range	Package Option[1]
AD9060JZ	0 to +70°C	Z-68
AD9060JE	0 to +70°C	E-68A
AD9060KZ	0 to +70°C	Z-68
AD9060KE	0 to +70°C	E-68A
AD9060SZ[2]	−55°C to +125°C	Z-68
AD9060SE[2]	−55°C to +125°C	E-68A
AD9060TZ[2]	−55°C to +125°C	Z-68
AD9060TE[2]	−55°C to +125°C	E-68A

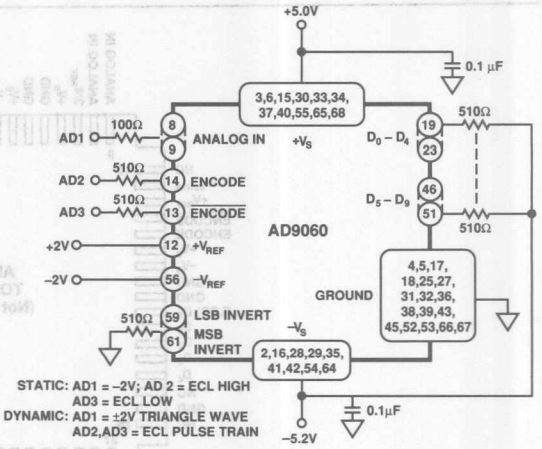
AD9060 Pin Designations



AD9060 PIN DESCRIPTIONS

Pin No.	Name	Function
1	$1/2_{REF}$	Midpoint of internal reference ladder.
2, 16, 28, 29, 35, 41, 42, 54, 64	$-V_S$	Negative supply voltage; nominally −5.2 V ±5%.
3, 6, 15, 30, 33, 34, 37, 40, 65, 68	$+V_S$	Positive supply voltage; nominally +5 V ±5%.
4, 5, 17, 18, 25, 27, 31, 32, 36, 38, 39, 43, 45, 52, 53, 66, 67	GROUND	All ground pins should be connected together and to low-impedance ground plane.
7	$3/4_{REF}$	Three-quarter point of internal reference ladder.
8, 9	ANALOG IN	Analog input; nominally between ±1.75 V.
11	$+V_{SENSE}$	Voltage sense line to most positive point on internal resistor ladder. Normally +1.75 V.
12	$+V_{REF}$	Voltage force connection for top of internal reference ladder. Normally driven to provide +1.75 V at $+V_{SENSE}$.
13	$\overline{\text{ENCODE}}$	Differential ECL convert signal which starts digitizing process.
14	ENCODE	ECL-compatible convert command used to begin digitizing process.
19–23, 46–50	D_0–D_9	ECL-compatible digital output data.
51	OVERFLOW	ECL-compatible output indicating ANALOG IN > $+V_{SENSE}$.
56	$-V_{REF}$	Voltage force connection for bottom of internal reference ladder. Normally driven to provide −1.75 V at $-V_{SENSE}$.
57	$-V_{SENSE}$	Voltage sense line to most negative point on internal resistor ladder. Normally −1.75 V.
59	LSBs INVERT	Normally grounded. When connected to $+V_S$, lower order bits (D_0–D_8) are inverted. Not ECL-compatible.
61	MSB INVERT	Normally grounded. When connected to $+V_S$, most significant bit (MSB; D_9) is inverted. Not ECL-compatible.
63	$1/4_{REF}$	One-quarter point of internal reference ladder.

MIL-STD-883 Compliance Information

The AD9060 devices are classified within Microcircuits Group 57, Technology Group D (bipolar A/D converters) and are constructed in accordance with MIL-STD-883. The AD9060 is electrostatic sensitive and falls within electrostatic sensitivity classification Class 1. Percent Defective Allowance (PDA) is computed based on Subgroup 1 of the specified Group A test list. Quality Assurance (QA) screening is in accordance with Alternate Method A of Method 5005.

The following apply: Burn-In per 1015; Life Test per 1005; Electrical Testing per 5004. (Note: Group A electrical testing assumes $T_A = T_C = T_J$.) MIL-STD-883-compliant devices are marked with "C" to indicate compliance.

AD9060 Burn-In Connections

THEORY OF OPERATION

Refer to the AD9060 block diagram. As shown, the AD9060 uses a modified "flash," or parallel, A/D architecture. The analog input range is determined by an external voltage reference ($+V_{REF}$ and $-V_{REF}$), nominally ±1.75 V. An internal resistor ladder divides this reference into 512 steps, each representing two quantization levels. Taps along the resistor ladder ($1/4_{REF}$, $1/2_{REF}$ and $3/4_{REF}$) are provided to optimize linearity. Rated performance is achieved by driving these points at 1/4, 1/2 and 3/4, respectively, of the voltage reference range.

The A/D conversion for the nine most significant bits (MSBs) is performed by 512 comparators. The value of the least significant bit (LSB) is determined by a unique interpolation scheme between adjacent comparators. The decoding logic processes the comparator outputs and provides a 10-bit code to the output stage of the converter.

Flash architecture has an advantage over other A/D architectures because conversion occurs in one step. This means the performance of the converter is limited primarily by the speed and matching of the individual comparators. In the AD9060, an innovative interpolation scheme takes advantage of flash architecture but minimizes the input capacitance, power and device count usually associated with that method of conversion.

These advantages occur because of using only half the normal number of input comparator cells to accomplish the conversion. In addition, a proprietary decoding scheme minimizes error codes. Input control pins allow the user to select from among Binary, Inverted Binary, Twos Complement and Inverted Twos Complement coding (See AD9060 Truth Table).

APPLICATIONS

Many of the specifications used to describe analog/digital converters have evolved from system performance requirements in these applications. Different systems emphasize particular specifications, depending on how the part is used. The following applications highlight some of the specifications and features that make the AD9060 attractive in these systems.

Wideband Receivers

Radar and communication receivers (baseband and direct IF digitization), ultrasound medical imaging, signal intelligence and spectral analysis all place stringent ac performance requirements on analog-to-digital converters (ADCs). Frequency domain characterization of the AD9060 provides signal-to-noise ratio (SNR) and harmonic distortion data to simplify selection of the ADC.

Receiver sensitivity is limited by the *Signal-to-Noise Ratio (SNR)* of the system. The SNR for an ADC is measured in the frequency domain and calculated with a Fast Fourier Transform (FFT). The SNR equals the ratio of the fundamental component of the signal (rms amplitude) to the rms value of the "noise." The noise is the sum of all other spectral components, including harmonic distortion, but excluding dc.

Good receiver design minimizes the level of spurious signals in the system. Spurious signals developed in the ADC are the result of imperfections in the device transfer function (nonlinearities, delay mismatch, varying input impedance, etc.). In the ADC, these spurious signals appear as *Harmonic Distortion*. Harmonic Distortion is also measured with an FFT and is specified as the ratio of the fundamental component of the signal (rms amplitude) to the rms value of the worst case harmonic (usually the 2nd or 3rd).

Two-Tone Intermodulation Distortion (IMD) is a frequently cited specification in receiver design. In narrow-band receivers, third-order IMD products result in spurious signals in the pass band of the receiver. Like mixers and amplifiers, the ADC is characterized with two, equal-amplitude, pure input frequencies. The IMD equals the ratio of the power of either of the two input signals to the power of the strongest third-order IMD signal. Unlike mixers and amplifiers, the IMD does not always behave as it does in linear devices (reduced input levels do not result in predictable reductions in IMD).

Performance graphs provide typical harmonic and SNR data for the AD9060 for increasing analog input frequencies. In choosing an A/D converter, always look at the dynamic range for the analog input frequency of interest. The AD9060 specifications provide guaranteed minimum limits at three analog test frequencies.

Aperture Delay is the delay between the rising edge of the ENCODE command and the instant at which the analog input is sampled. Many systems require simultaneous sampling of more than one analog input signal with multiple ADCs. In these situations, timing is critical and the absolute value of the aperture delay is not as critical as the matching between devices.

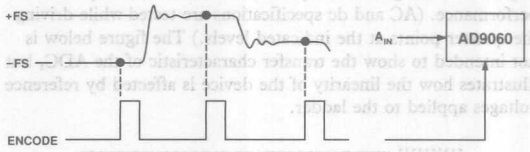
Aperture Uncertainty, or jitter, is the sample-to-sample variation in aperture delay. This is especially important when sampling high slew rate signals in wide bandwidth systems. Aperture uncertainty is one of the factors which degrades dynamic performance as the analog input frequency is increased.

Digitizing Oscilloscopes

Oscilloscopes provide amplitude information about an observed waveform with respect to time. Digitizing oscilloscopes must accurately sample this signal, without distorting the information to be displayed.

One figure of merit for the ADC in these applications is *Effective Number of Bits (ENOBs)*. ENOB is calculated with a sine wave curve fit and equals:

$$ENOB = N - LOG_2 [Error\ (measured)/Error\ (ideal)]$$



N is the resolution (number of bits) of the ADC. The measured error is the actual rms error calculated from the converter outputs with a pure sine wave input.

The *Analog Bandwidth* of the converter is the analog input frequency at which the spectral power of the fundamental signal is reduced 3 dB from its low frequency value. The analog bandwidth is a good indicator of a converter's slewing capabilities.

The *Maximum Conversion Rate* is defined as the encode rate at which the SNR for the lowest analog signal test frequency tested drops by no more than 3 dB below the guaranteed limit.

Imaging

Visible and infrared imaging systems both require similar characteristics from ADCs. The signal input (from a CCD camera, or multiplexer) is a time division multiplexed signal consisting of a series of pulses whose amplitude varies in direct proportion to the intensity of the radiation detected at the sensor. These varying levels are then digitized by applying encode commands at the correct times, as shown below.

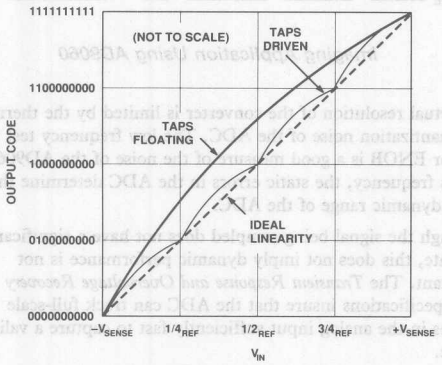
Imaging Application Using AD9060

The actual resolution of the converter is limited by the thermal and quantization noise of the ADC. The low frequency test for SNR or ENOB is a good measure of the noise of the AD9060. At this frequency, the static errors in the ADC determine the useful dynamic range of the ADC.

Although the signal being sampled does not have a significant slew rate, this does not imply dynamic performance is not important. The *Transient Response and Overvoltage Recovery Time* specifications insure that the ADC can track full-scale changes in the analog input sufficiently fast to capture a valid sample.

Transient Response is the time required for the AD9060 to achieve full accuracy when a step function is applied. *Overvoltage Recovery Time* is the time required for the AD9060 to recover to full accuracy after an analog input signal 150% of full scale is reduced to the full-scale range of the converter.

Professional Video



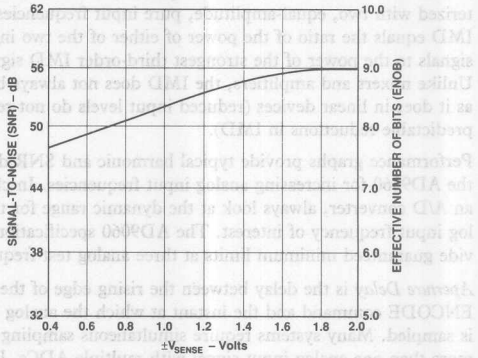
Digital Signal Processing (DSP) is now common in television production. Modern studios rely on digitized video to create state-of-the-art special effects. Video instrumentation also requires high resolution ADCs for studio quality measurement and frame storage.

The AD9060 provides sufficient resolution for these demanding applications. Conversion speed, dynamic performance and analog bandwidth are suitable for digitizing both composite and RGB video sources.

USING THE AD9060

Voltage References

The AD9060 requires that the user provide two voltage references: $+V_{REF}$ and $-V_{REF}$. These two voltages are applied across an internal resistor ladder (nominally 37 Ω) and set the analog input voltage range of the converter. The voltage references should be driven from a stable, low impedance source. In addition to these two references, three evenly spaced taps on the resistor ladder ($1/4_{REF}$, $1/2_{REF}$, $3/4_{REF}$) are available. Providing a reference to these quarter points on the resistor ladder will improve the integral linearity of the converter and improve ac performance. (AC and dc specifications are tested while driving the quarter points at the indicated levels.) The figure below is not intended to show the transfer characteristic of the ADC, but illustrates how the linearity of the device is affected by reference voltages applied to the ladder.



Effect of Reference Taps on Linearity

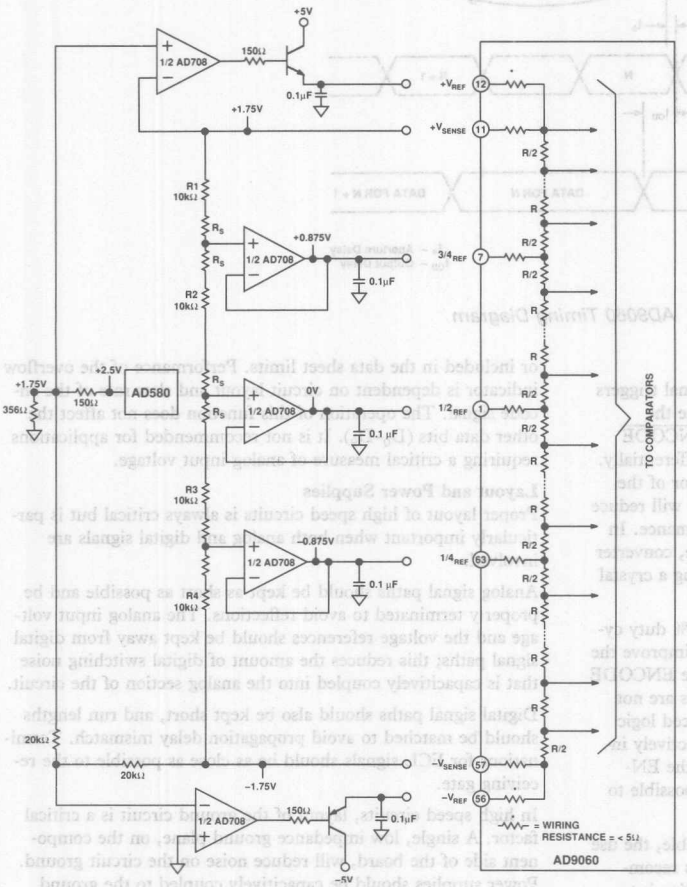
Resistance between the reference connections and the taps of the first and last comparators causes offset errors. These errors, called "top and bottom of the ladder offsets," can be nulled by using the voltage sense lines, $+V_{SENSE}$ and $-V_{SENSE}$, to adjust the reference voltages. Current through the sense lines should be limited to less than 100 μA. Excessive current drawn through the voltage sense lines will affect the accuracy of the sense line voltage.

The next page shows a reference circuit which nulls out the offset errors using two op amps and provides appropriate voltage references to the quarter-point taps. Feedback from the sense lines causes the op amps to compensate for the offset errors. The two transistors limit the amount of current drawn directly from the op amps; resistors at the base connections stabilize their operation. The 10 kΩ resistors (R1–R4) between the voltage sense lines form an external resistor ladder; the quarter point voltages are taken off this external ladder and buffered by an op amp. The actual values of resistors R1–R4 are not critical, but they should match well and be large enough (≥10 kΩ) to limit the amount of current drawn from the voltage sense lines.

The select resistors (R_S) shown in the schematic (each pair can be a potentiometer) are chosen to adjust the quarter-point voltage references, but are not necessary if R1–R4 match within 0.05%.

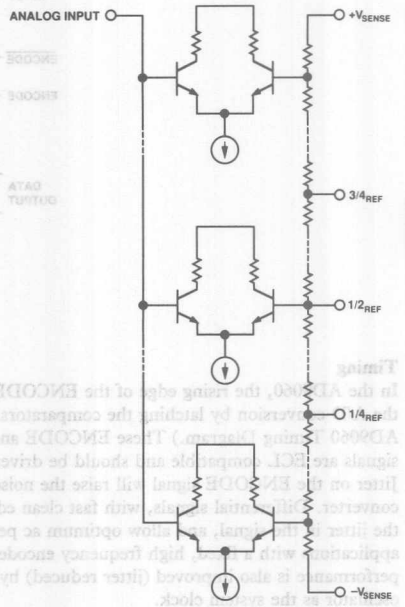
AD9060 SNR and ENOB vs. Reference Voltage

An alternative approach for defining the quarter-point references of the resistor ladder is to evaluate the integral linearity error of an individual device, and adjust the voltage at the quarter-points to minimize this error. This may improve the low frequency ac performance of the converter.



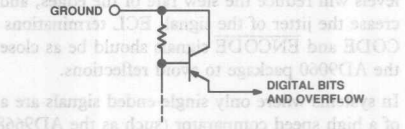
Performance of the AD9060 has been optimized with an analog input voltage of ±1.75 V (as measured at $\pm V_{SENSE}$). If the analog input range is reduced below these values, relatively larger differential nonlinearity errors may result because of comparator mismatches. As shown in the figure below, performance of the converter is a function of $\pm V_{SENSE}$.

Applying a voltage greater than 4 V across the internal resistor ladder will cause current densities to exceed rated values, and may cause permanent damage to the AD9060. The design of the reference circuit should limit the voltage available to the references.

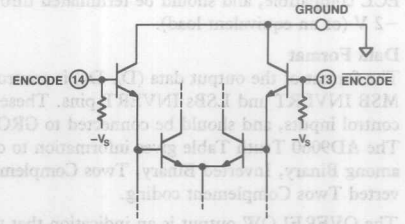


Analog Input Signal

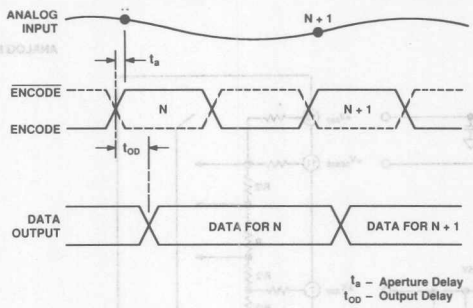
The signal applied to ANALOG IN drives the inputs of 512 parallel comparator cells (see Equivalent Analog Input figure). This connection typically has an input resistance of 7 kΩ, and input capacitance of 45 pF. The input capacitance is nearly constant over the analog input voltage range, as shown in the graph which illustrates that characteristic.



The analog input signal should be driven from a low distortion, low noise amplifier. A good choice is the AD9617, a wide bandwidth, monolithic operational amplifier with excellent ac and dc performance. The input capacitance should be isolated by a small series resistor (24 Ω for the AD9617) to improve the ac performance of the amplifier (see AD9060/PCB Evaluation Board Block Diagram).



AD9060 Reference Circuit



AD9060 Equivalent Analog Input

AD9060 Equivalent Digital Outputs

AD9060 Encode and $\overline{\text{Encode}}$ Equivalent Circuits

AD9060 Timing Diagram

Timing

In the AD9060, the rising edge of the ENCODE signal triggers the A/D conversion by latching the comparators. (See the AD9060 Timing Diagram.) These ENCODE and $\overline{\text{ENCODE}}$ signals are ECL compatible and should be driven differentially. Jitter on the ENCODE signal will raise the noise floor of the converter. Differential signals, with fast clean edges, will reduce the jitter in the signal, and allow optimum ac performance. In applications with a fixed, high frequency encode rate, converter performance is also improved (jitter reduced) by using a crystal oscillator as the system clock.

The AD9060 units are designed to operate with a 50% duty cycle encode signal; adjustment of the duty cycle may improve the dynamic performance of individual devices. Since the ENCODE and $\overline{\text{ENCODE}}$ signals are differential, the logic levels are not critical. Users should remember, however, that reduced logic levels will reduce the slew rate of the edges, and effectively increase the jitter of the signal. ECL terminations for the ENCODE and $\overline{\text{ENCODE}}$ signals should be as close as possible to the AD9060 package to avoid reflections.

In systems where only single-ended signals are available, the use of a high speed comparator (such as the AD96685) is recommended to convert to differential signals. An alternative is to connect +1.3 V (ECL midpoint) to $\overline{\text{ENCODE}}$ and drive the ENCODE connection single ended. In such applications, clean, fast edges are necessary to minimize jitter in the signal.

Output data of the AD9060, D_0–D_9 and OVERFLOW, are also ECL compatible, and should be terminated through 100 Ω to −2 V (or an equivalent load).

Data Format

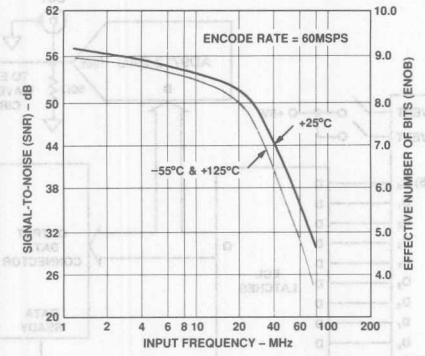
The format of the output data (D_0–D_9) is controlled by the MSB INVERT and LSBs INVERT pins. These inputs are dc control inputs, and should be connected to GROUND or $+V_S$. The AD9060 Truth Table gives information to choose from among Binary, Inverted Binary, Twos Complement and Inverted Twos Complement coding.

The OVERFLOW output is an indication that the analog input signal has exceeded the voltage at $+V_{SENSE}$. The accuracy of the overflow transition voltage and output delay are not tested or included in the data sheet limits. Performance of the overflow indicator is dependent on circuit layout and slew rate of the encode signal. The operation of this function does not affect the other data bits (D_0–D_9). It is not recommended for applications requiring a critical measure of analog input voltage.

Layout and Power Supplies

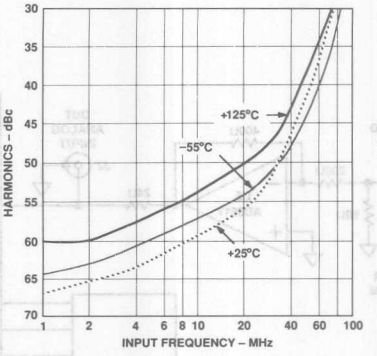
Proper layout of high speed circuits is always critical but is particularly important when both analog and digital signals are involved.

Analog signal paths should be kept as short as possible and be properly terminated to avoid reflections. The analog input voltage and the voltage references should be kept away from digital signal paths; this reduces the amount of digital switching noise that is capacitively coupled into the analog section of the circuit.



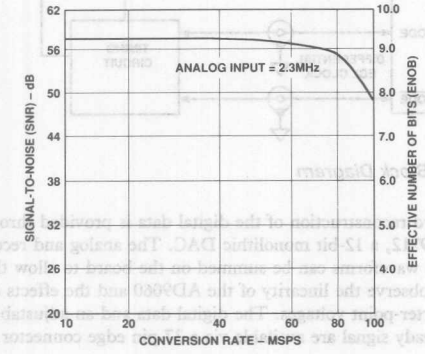
Digital signal paths should also be kept short, and run lengths should be matched to avoid propagation delay mismatch. Terminations for ECL signals should be as close as possible to the receiving gate.

In high speed circuits, layout of the ground circuit is a critical factor. A single, low impedance ground plane, on the component side of the board, will reduce noise on the circuit ground. Power supplies should be capacitively coupled to the ground plane to reduce noise in the circuit. Multilayer boards allow designers to lay out signal traces without interrupting the ground plane and provide low impedance power planes.



It is especially important to maintain the continuity of the ground plane under and around the AD9060. In systems with dedicated digital and analog grounds, all grounds of the AD9060 should be connected to the analog ground plane.

The power supplies ($+V_S$ and $-V_S$) of the AD9060 should be isolated from the supplies used for external devices; this further reduces the amount of noise coupled into the A/D converter. Sockets limit the dynamic performance and should be used only for prototypes or evaluation—PCK Elastomerics Part No. CCS-68-55 is recommended for the LCC package. (Tel. 215-672-0787)



An evaluation board is available to aid designers and provide a suggested layout.

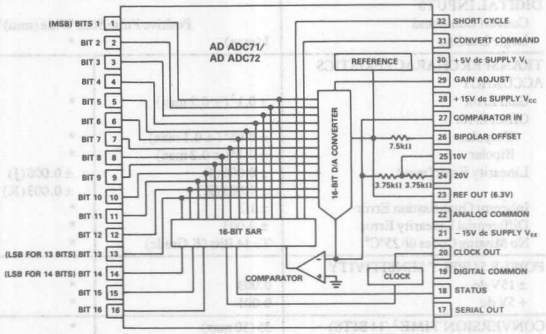
The overflow bit is always 0 except where noted in parentheses ( ). MSB INVERT and LSBs INVERT are considered dc controls.

AD9060 Truth Table

AD9060/PCB Evaluation Board Block Diagram

AD9060/PCB EVALUATION BOARD

The AD9060/PCB Evaluation Board is available from the factory and is shown here in block diagram form. The board includes a reference circuit that allows the user to adjust both references and the quarter-point voltages. The AD9617 is included as the drive amplifier, and the user can configure the gain from −1 to −15.



On-board reconstruction of the digital data is provided through the AD9712, a 12-bit monolithic DAC. The analog and reconstructed waveforms can be summed on the board to allow the user to observe the linearity of the AD9060 and the effects of the quarter-point voltages. The digital data and an adjustable Data Ready signal are available via a 37-pin edge connector.

AD ADC71/AD ADC72

FEATURES

Complete 16-Bit Converter With Reference and Clock
±0.003% Maximum Nonlinearity
No Missing Codes to 14 Bits
Fast Conversion – 35μs (14 Bit)
Short Cycle Capability
Parallel and Serial Logic Outputs
Low Power: 645mW Typical
Industry Standard Pin Out

FUNCTIONAL BLOCK DIAGRAM

PRODUCT DESCRIPTION

The AD ADC71 and AD ADC72 are high resolution 16-bit hybrid IC analog-to-digital converters including reference, clock, and laser-trimmed thin-film components. The package is a compact 32-pin hermetic ceramic DIP. The thin-film scaling resistors allow analog input ranges of ±2.5V, ±5V, ±10V, 0 to +5V, 0 to +10V, and 0 to +20V.

Important performance characteristics of the devices are maximum linearity error of ±0.003% of FSR (AD ADC71K, AD ADC72K and B), and maximum conversion time of 50μs. This performance is due to innovative design and the use of proprietary monolithic D/A converter chips. Laser-trimmed thin-film resistors provide the linearity and wide temperature range for no missing codes.

The AD ADC71 and AD ADC72 provide data in parallel form with corresponding clock and status outputs. The AD ADC71 also provides data in serial form. All digital inputs and outputs are TTL compatible.

APPLICATIONS

The AD ADC71 and AD ADC72 are excellent for use in applications requiring 14-bit accuracy over extended temperature ranges. Typical applications include medical and analytic instrumentation, precision measurement for industrial robots, automatic test equipment (ATE), multichannel data acquisition systems, servo control systems and anywhere that excellent stability and wide dynamic range in the smallest space is required.

PRODUCT HIGHLIGHTS

1. The AD ADC71 and AD ADC72 provide 16-bit resolution with maximum linearity error less than ±0.003% (±0.006% for J and A grades) at 25°C.
2. Conversion time is 35μs typical to 14 bits with short cycle capability.
3. Two binary codes are available on the AD ADC71 and AD ADC72 output. They are complementary straight binary (CSB) for unipolar input voltage ranges and complementary offset binary (COB) for bipolar input ranges. Complementary two's complement (CTC) coding may be obtained by inverting Pin 1 (MSB).
4. The proprietary chips used in this hybrid design provide excellent stability over temperature and lower chip count for improved reliability.

ORDERING GUIDE

Model	Linearity Error (Max)	Specification Temp Range	Package Option*
AD ADC71JD	±0.006% of FSR	0 to +70°C	Ceramic (DH-32E)

12-Bit Successive Approximation Integrated Circuit A/D Converter

AD ADC80

FEATURES

- True 12-Bit Operation: Max Nonlinearity ±0.012%
- Low Gain T.C.: ±30ppm/°C max
- Low Power: 800mW
- Fast Conversion Time: 25μs
- Precision 6.3V Reference for External Application
- Short-Cycle Capability
- Serial or Parallel Data Outputs
- Monolithic DAC with Scaling Resistors for Stability
- Low Chip Count—High Reliability
- Industry Standard Pinout
- "Z" Models for ±12V Supplies

FUNCTIONAL BLOCK DIAGRAM

PRODUCT DESCRIPTION

The AD ADC80 is a complete 12-bit successive approximation analog-to-digital converter that includes an internal clock, reference and comparator. Its hybrid IC design utilizes MSI digital and linear monolithic chips in conjunction with a 12-bit monolithic DAC to provide modular performance and versatility with IC size, price and reliability.

Important performance characteristics of the AD ADC80 include a maximum linearity error at +25°C of ±0.012%, max gain T.C. of 30ppm/°C, typical power dissipation of 800mW and max conversion time of 25μs. Monotonic operation of the feedback D/A converter guarantees no missing codes over the temperature range of -25°C to +85°C.

The design of the AD ADC80 includes scaling resistors that provide analog signal ranges of ±2.5, ±5.0, ±10, 0 to +5 or 0 to +10 volts. The 6.3V precision reference may be used for external applications. All digital signals are fully DTL and TTL compatible; output data may be read in both serial and parallel form.

The AD ADC80 is available in two performance grades, the AD ADC80-12 (0.012% of FSR max) and the AD ADC80-10 (0.048% of FSR max). Both grades are specified for use over the -25°C to +85°C temperature range and both are available in a 32-pin ceramic DIP.

PRODUCT HIGHLIGHTS

1. The AD ADC80 is a complete 12-bit A/D converter. No external components are required to perform a conversion.
2. A monolithic 12-bit feedback DAC is used for reduced chip count and higher reliability.
3. The internal buried zener reference is laser trimmed to 6.3 volts. The reference voltage is available externally and can supply up to 1.5mA beyond that required for the reference and bipolar offset current.
4. The scaling resistors are included on the monolithic DAC for exceptional thermal tracking.
5. The AD ADC80 directly replaces other devices of this type with significant increases in performance.
6. The fast conversion rate of the AD ADC80 makes it an excellent choice for applications requiring high system throughput rates.
7. The short cycle and external clock options are provided for applications requiring faster conversion speeds or lower resolutions.

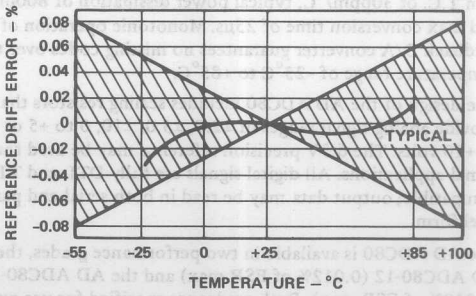

Figure 4. Reference Drift—% Error vs. Temperature

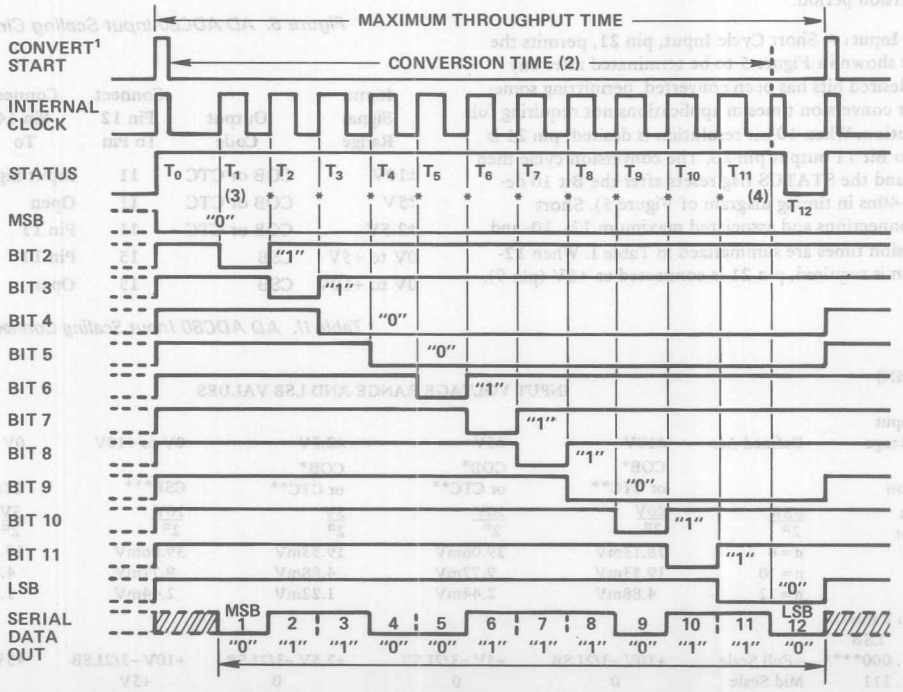
THEORY OF OPERATION



On receipt of a CONVERT START command, the AD ADC80 converts the voltage at its analog input into an equivalent 12-bit binary number. This conversion is accomplished as follows: the 12-bit successive-approximation register (SAR) has its 12-bit outputs connected both to the device bit output pins and to the corresponding bit inputs of the feedback DAC. The analog input is successively compared to the feedback DAC output, one bit at a time (MSB first, LSB last). The decision to keep or reject each bit is then made at the completion of each bit comparison period, depending on the state of the comparator at that time.

TIMING

The timing diagram is shown in Figure 5. Receipt of a CONVERT START signal sets the STATUS flag, indicating conversion in progress. This, in turn, removes the inhibit applied to the gated clock, permitting it to run through 13 cycles. All SAR parallel bit and STATUS flip-flops are initialized on the leading edge, and the gated clock inhibit signal is removed on the trailing edge of the CONVERT START signal. At time t_0, B_1 is reset and B_2 –B_{12} are set unconditionally. At t_1 the Bit 1 decision is made (keep) and Bit 2 is unconditionally reset. At t_2, the Bit 2 decision is made (keep) and Bit 3 is reset unconditionally. This sequence continues until the Bit 12 (LSB) decision (keep) is made at t_{12}. After a 40ns delay period, the STATUS flag is reset, indicating that the conversion is complete and that the parallel output data is valid. Resetting the STATUS flag restores the gated clock inhibit signal, forcing the clock output to the Logic "0" state.

Corresponding serial and parallel data bits become valid on the same positive-going clock edge. Serial data does not change and is guaranteed valid on negative-going clock edges, however; serial data can be transferred quite simply by clocking it into a receiving shift register on these edges (see Figure 5).

Incorporation of this 40ns delay guarantees that the parallel (and serial) data are valid at the Logic "1" to "0" transition of the STATUS flag, permitting parallel data transfer to be initiated by the trailing edge of the STATUS signal.

NOTES:
1. THE CONVERT START PULSE WIDTH IS 100ns MIN AND MUST REMAIN LOW DURING A CONVERSION. THE CONVERSION IS INITIATED BY THE "RISING EDGE" OF THE CONVERT COMMAND.
2. 25μs FOR 12 BITS AND 21μs FOR 10 BITS (MAX).
3. MSB DECISION
4. LSB DECISION 40ns PRIOR TO THE STATUS GOING LOW

*BIT DECISIONS

Figure 5. Timing Diagram (Binary Code 011001110110)

Both parallel and serial data from TTL storage registers are in negative true form. Parallel data output coding is complementary binary for unipolar ranges and either complementary offset binary or complementary two's complement binary, depending on whether BIT 1 (pin 6) or its logical inverse BIT 1 (pin 8) is used as the MSB. Parallel data becomes valid approximately 40ns before the STATUS flag returns to Logic "0", permitting parallel data transfer to be clocked on the "1" to "0" transition of the STATUS flag.

Serial data coding is complementary binary for unipolar input ranges and complementary offset binary for bipolar input ranges. Serial output is by bit (MSB first, LSB last) in NRZ (non-return-to-zero) format. Serial and parallel data outputs change state on positive-going clock edges. Serial data is guaranteed valid 200ns after the rising clock edges, permitting serial data to be clocked directly into a receiving register on these edges as shown in Figure 5. There are 13 negative-going clock edges in the complete 12-bit conversion cycle, as shown in Figure 5. The first edge shifts an invalid bit into the register, which is shifted out on the 13th negative-going clock edge. All serial data bits will have been correctly transferred and be in the receiving shift register locations shown at the completion of the conversion period.

Short Cycle Input: A Short Cycle Input, pin 21, permits the timing cycle shown in Figure 5 to be terminated after any number of desired bits has been converted, permitting somewhat shorter conversion times in applications not requiring full 12-bit resolution. When 10-bit resolution is desired, pin 21 is connected to Bit 11 output pin 28. The conversion cycle then terminates, and the STATUS flag resets after the Bit 10 decision (t_{10} +40ns in timing diagram of Figure 5). Short Cycle pin connections and associated maximum 12-, 10- and 8-bit conversion times are summarized in Table I. When 12-bit resolution is required, pin 21 is connected to +5V (pin 9).

9	12	0.024	25	t_{12} +40ns
28	10	0.100	21	t_{10} +40ns
30	8	0.390	17	t_8 +40ns

Table I. Short Cycle Connections

INPUT SCALING

The AD ADC80 input should be scaled as close to the maximum input signal range as possible in order to utilize the maximum signal resolution of the A/D converter. Connect the input signal as shown in Table II. See Figure 6 for circuit details.

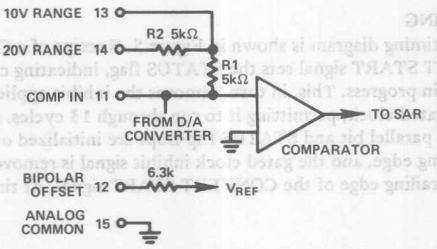


Figure 6. AD ADC80 Input Scaling Circuit

Input Signal Range	Output Code	Connect Pin 12 To Pin	Connect Pin 14 To	Connect Input Signal To

Table III. Input Voltages and Code Definitions

OFFSET ADJUSTMENT

The zero adjust circuit consists of a potentiometer connected across $\pm V_S$ with its slider connected through a 1.8MΩ resistor to Comparator Input pin 11 for all ranges. As shown in Figure 7 the tolerance of this fixed resistor is not critical, and a carbon composition type is generally adequate. Using a carbon composition resistor having a −1200ppm/°C tempco contributes a worst-case offset tempco of $8 \times 244 \times 10^{-6} \times 1200$ppm/°C = 2.3ppm/°C of FSR, if the OFFSET ADJ potentiometer is set at either end of its adjustment range. Since the maximum offset adjustment required is typically no more than ±4LSB, use of a carbon composition offset summing resistor typically contributes no more than 1ppm/°C of FSR offset tempco.

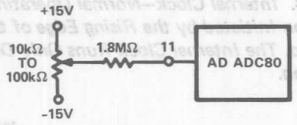

Figure 7. Offset Adjustment Circuit

An alternate offset adjust circuit, which contributes negligible offset tempco if metal film resistors (tempco <100 ppm/°C) are used, is shown in Figure 8.

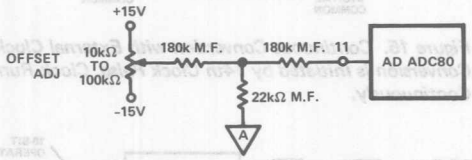

Figure 8. Low Tempco Zero Adjustment Circuit

In either zero adjust circuit, the fixed resistor connected to pin 11 should be located close to this pin to keep the pin 11 connection runs short (Comparator Input pin 11 is quite sensitive to external noise pick-up).

GAIN ADJUSTMENT

The gain adjust circuit consists of a potentiometer connected across $\pm V_S$ with its slider connected through a 10MΩ resistor to the gain adjust pin 16 as shown in Figure 9.

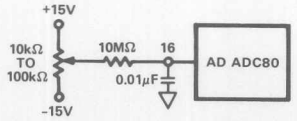

Figure 9. Gain Adjustment Circuit

An alternate gain adjust circuit which contributes negligible gain tempco if metal film resistors (Tempco <100ppm/°C) are used is shown in Figure 10.

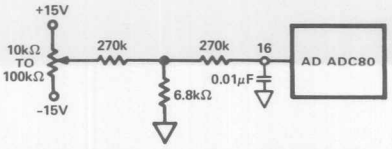

Figure 10. Low Tempco Gain Adjustment Circuit

CALIBRATION

External ZERO ADJ and GAIN ADJ potentiometers, connected as shown in Figures 11 and 12, are used for device calibration. To prevent interaction of these two adjustments, Zero is always adjusted first and then Gain. Zero is adjusted with the analog input near the most negative end of the analog range (0 for unipolar and −FS for bipolar input ranges). Gain is adjusted with the analog input near the most positive end of the analog range.

0 to +10V Range: Set analog input to +1LSB = +0.0024V. Adjust Zero for digital output = 111111111110. Zero is now calibrated. Set analog input to +FSR −2LSB = +9.9952V. Adjust Gain for 000000000001 digital output code; full-scale (Gain) is now calibrated. Half-scale calibration check: set analog input to +5.0000V; digital output code should be 011111111111.

−10V to +10V Range: Set analog input to −9.9951V; adjust Zero for 111111111110 digital output (complementary offset binary) code. Set analog input to +9.9902V; adjust Gain for 000000000001 digital output (complementary offset binary) code. Half-scale calibration check: set analog input to 0.0000V; digital output (complementary offset binary) code should be 0111111111111.

Other Ranges: Representative digital coding for 0 to +10V and −10V to +10V ranges is given above. Coding relationships and calibration points for 0 to +5V, −2.5V to +2.5V and −5V to +5V ranges can be found by halving the corresponding code equivalents listed for the 0 to +10V and −10V to +10V ranges, respectively.

Zero and full-scale calibration can be accomplished to a precision of approximately ±1/4LSB using the static adjustment procedure described above. By summing a small sine or triangular-wave voltage with the signal applied to the analog input, the output can be cycled through each of the calibration codes of interest to more accurately determine the center (or end points) of each discrete quantization level. A detailed description of this dynamic calibration technique is presented in "A/D Conversion Notes," D. Sheingold, Analog Devices, Inc., 1977, Part II, Chapter 3.

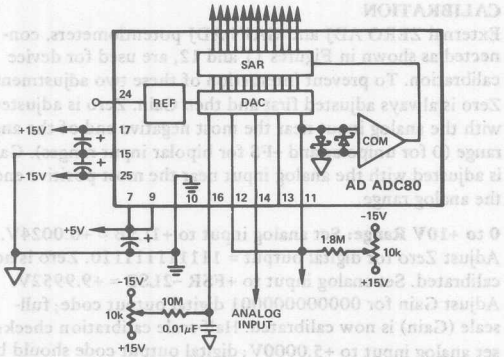

Figure 12. Analog and Power Connections for Bipolar ±10V Input Range

GROUNDING

Many data-acquisition components have two or more ground pins which are not connected together within the device. These "grounds" are usually referred to as the Logic Power Return, Analog Common (Analog Power Return), and Analog Signal Ground. These grounds must be tied together at one point, usually at the system power-supply ground. Ideally, a single solid ground would be desirable. However, since current flows through the ground wires and etch stripes of the circuit cards, and since these paths have resistance and inductance, hundreds of millivolts can be generated between the system ground point and the ground pin of the AD ADC80. Therefore, separate ground returns should be provided to minimize the current flow in the path from sensitive points to the system ground point and the two device grounds should be tied together. In this way supply currents and logic-gate return currents are not summed into the same return path as analog signals where they would cause measurement errors.

Each of the AD ADC80's supply terminals should be capacitively decoupled as close to the AD ADC80 as possible. A large value capacitor such as 1μF in parallel with a 0.1μF capacitor is usually sufficient. Analog supplies are bypassed to the Analog Power Return pin and the logic supply is bypassed to the Logic Power Return pin.

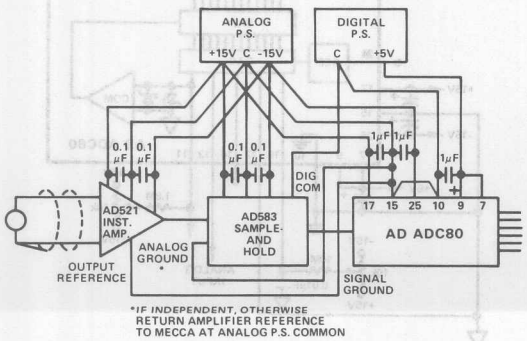

Figure 13. Basic Grounding Practice

CONTROL MODES

The timing sequence of the AD ADC80 allows the device to be easily operated in a variety of systems with different control modes. The most common control modes are illustrated in Figures 14–16.

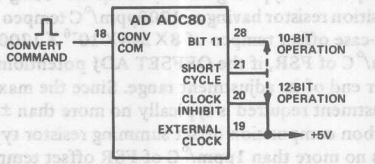

Figure 14. Internal Clock—Normal Operating Mode. Conversion Initiated by the Rising Edge of the Convert Command. The Internal Clock Runs Only During Conversion.

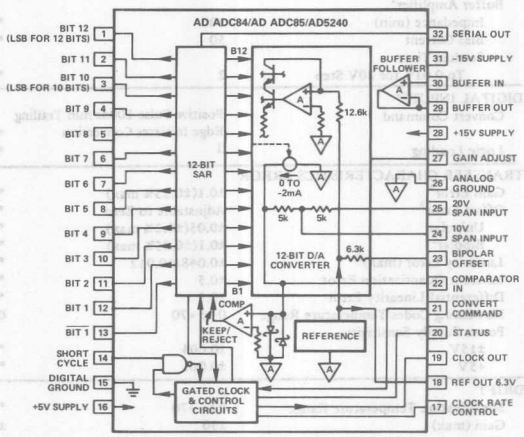
Fast, Complete 12-Bit A/D Converters

AD ADC84/AD ADC85/AD5240

FEATURES



Performance

- Complete 12-Bit A/D Converter with Reference and Clock
- Fast Successive Approximation Conversion: 10μs or 5μs
- Buried Zener Reference for Long Term Stability and Low Gain T.C.: 10ppm/°C
- Max Nonlinearity: <±0.012%
- Low Power: 880mW Typical
- Low Chip Count – High Reliability
- Industry Standard Pin Out
- "Z" Models for ±12V Operation Available
- MIL-STD-883B Processing Available

Versatility

- Negative-True Parallel or Serial Logic Outputs
- Short Cycle Capability
- Precision +6.3V Reference for External Applications

FUNCTIONAL BLOCK DIAGRAM

PRODUCT DESCRIPTION

The AD ADC84/AD ADC85/AD5240 series devices are high-speed, low-cost 10- and 12-bit successive approximation analog-to-digital converters that include internal clock, reference and comparator. Its hybrid IC design utilizes MSI digital and linear monolithic chips in conjunction with a 12-bit monolithic DAC to provide modular performance and versatility with IC size, price and reliability.

Important performance characteristics of the AD ADC84/AD ADC85/AD5240 series include a maximum linearity error at +25°C of ±0.012%, gain T.C. below 15ppm/°C, typical power dissipation of 880mW, and conversion time of less than 10μs for the 12-bit versions. Of considerable significance in severe and aerospace applications is the guaranteed performance from −55°C to +125°C of the AD ADC85S which is also available with environmental screening. Monotonic operation of the feedback D/A converter guarantees no missing codes over temperature ranges of 0 to +70°C, −25°C to +85°C, and −55°C to +125°C.

The design of the AD ADC84/AD ADC85/AD5240 includes scaling resistors that provide analog input signal ranges of ±2.5, ±5, ±10, 0 to +5, or 0 to +10 volts. Adding flexibility and value are the +6.3V precision reference, which also can be used for external applications, and the input buffer amplifier. All digital signals are fully DTL and TTL compatible, and the data output is negative-true and available in either serial or parallel form.

The AD ADC84/AD ADC85/AD5240 series devices are available in two different performance grades. The devices are specified for either 10-bit accuracy (±0.048% FSR max) or 12-bit accuracy (±0.012% FSR max) with 8.4μs, 10μs (AD ADC84/AD ADC85) and 4.1μs, 5μs (AD5240) max conversion times respectively.

The AD ADC84 and AD ADC85C specified for operation over the 0 to +70°C temperature range. The AD ADC85 and AD ADC85S are specified for the −25°C to +85°C, −55°C to +125°C ranges respectively.

PRODUCT HIGHLIGHTS

1. The AD ADC84/AD ADC85/AD5240 series devices are complete 12-bit A/D converters. No external components are required to perform a conversion.
2. The AD ADC84/AD ADC85/AD5240 directly replaces other devices of this type with significant increases in performance.
3. The fast conversion rates of the AD ADC84/AD ADC85 (10μs) and AD5240 (5μs) make them an excellent choice for applications requiring high system throughput rates.
4. The internal buried zener reference is laser trimmed to 6.3V ±0.1% and ±10ppm/°C typical T.C. The reference is available externally and can provide up to 1mA.
5. The integrated package construction provides high quality and reliability with small size and weight.
6. The monolithic 12-bit feedback DAC is used for reduced chip count and higher reliability.
7. The AD ADC85S/883B and AD5240SD/883B come processed to MIL-STD-883, Class B requirements (see ADI Military Products Databook).

NOTES

[1] Buffer Settling time adds to conversion speed when buffer is connected to input.

[2] DTL/TTL compatible Logic "0" = 0.8V max, Logic "1" = 2.0V min for digital output, Logic "0" = 0.4V max, Logic "1" = 2.4V min.

[3] Adjustable to zero.

[4] FSR means Full Scale Range.

[5] Guaranteed at V_{IN} = 0 volts.

[6] Error shown is the same as ±1/2LSB max error in % of FSR.

[7] See Table I.

[8] For ±12V operation add "Z" to model number. Input range limited to a maximum of ±5V.

[9] For package outline information see Package Information section.

OFFSET ADJUSTMENT

The zero adjust circuit consists of a potentiometer connected across $\pm V_S$ with its slider connected through a 1.8MΩ resistor to Comparator Input pin 22 for all ranges. As shown in Figure 5 the tolerance of this fixed resistor is not critical, and a carbon composition type is generally adequate. Using a carbon composition resistor having a −1200ppm/°C tempco contributes a worst-case offset tempco of $8 \times 244 \times 10^{-6} \times 1200$ppm/°C = 2.3ppm/°C of FSR, if the OFFSET ADJ potentiometer is set at either end of its adjustment range. Since the maximum offset adjustment required is typically no more than ±4LSB, use of a carbon composition offset summing resistor typically contributes no more than 1ppm/°C of FSR offset tempco.

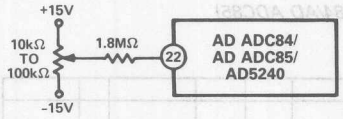

Figure 5. Offset Adjustment Circuit

An alternate offset adjust circuit, which contributes negligible offset tempco if metal film resistors (tempco <100 ppm/°C) are used, is shown in Figure 5.

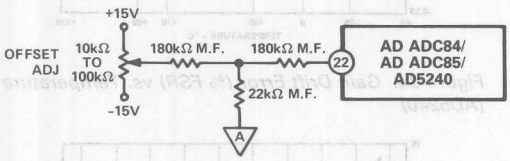

Figure 6. Low Tempco Zero Adjustment Circuit

In either zero adjust circuit, the fixed resistor connected to pin 22 should be located close to this pin to keep the pin connection runs short (Comparator Input pin 22 is quite sensitive to external noise pick-up).

GAIN ADJUSTMENT

The gain adjust circuit consists of a potentiometer connected across $\pm V_S$ with its slider connected through a 10MΩ resistor to the gain adjust pin 27 as shown in Figure 7.

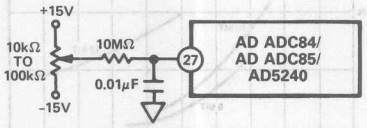

Figure 7. Gain Adjustment Circuit

An alternate gain adjust circuit which contributes negligible gain tempco if metal film resistors (Tempco <100ppm/°C) are used is shown in Figure 8.

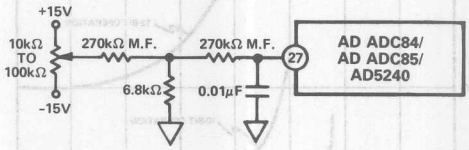

Figure 8. Low Tempco Gain Adjustment Circuit

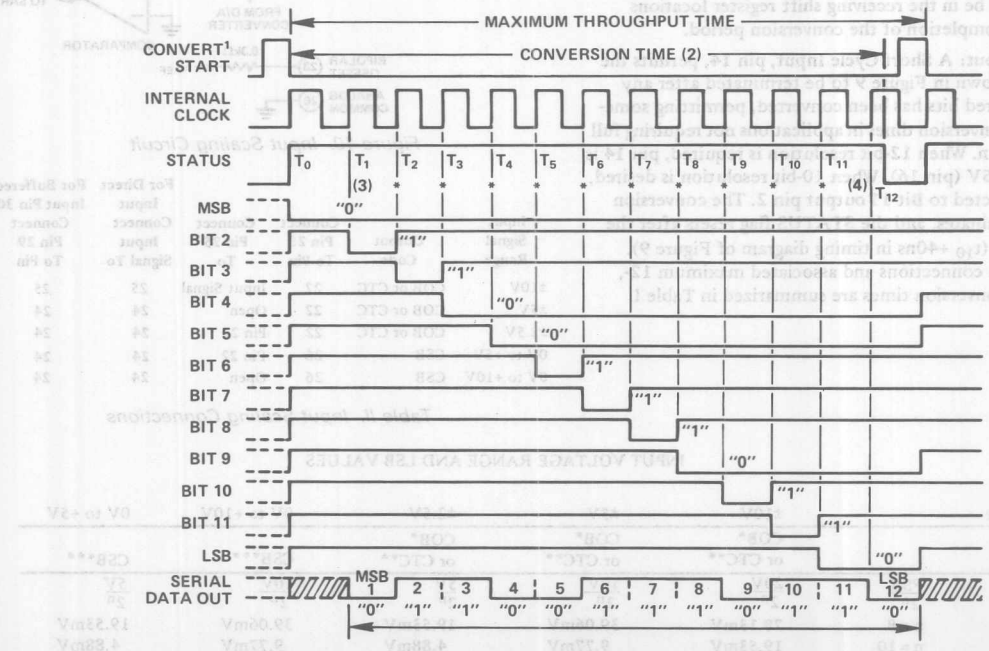
THEORY OF OPERATION



On receipt of a CONVERT START command, the AD ADC84/AD ADC85/AD5240 converts the voltage as its analog input into an equivalent 12-bit binary number. This conversion is accomplished as follows: the 12-bit successive-approximation register (SAR) has its 12-bit outputs connected both to the device bit output pins and to the corresponding bit inputs of the feedback DAC. The analog input is successively compared to the feedback DAC output, one bit at a time (MSB first, LSB last). The decision to keep or reject each bit is then made at the completion of each bit comparison period, depending on the state of the comparator at that time.

TIMING

The timing diagram is shown in Figure 9. Receipt of a CONVERT START signal sets the STATUS flag, indicating conversion in progress. This, in turn, removes the inhibit applied to the gated clock, permitting it to run through 13 cycles. All the SAR parallel bits, STATUS flip-flops, and the gated clock inhibit signal are initialized on the trailing edge of the CONVERT START signal. At time t_0, B_1 is reset and B_2 – B_{12} are set unconditionally. At t_1 the Bit 1 decision is made (keep) and Bit 2 is unconditionally reset. At t_2, the Bit 2 decision is made (keep) and Bit 3 is reset unconditionally. This sequence continues until the Bit 12 (LSB) decision (keep) is made at t_{12}. After a 40ns delay period, the STATUS flag is reset, indicating that the conversion is complete and that the parallel output data is valid. Resetting the STATUS flag restores the gated clock inhibit signal, forcing the clock output to the Logic "0" state.

Corresponding serial and parallel data bits become valid on the same positive-going clock edge. Serial data does not change and is guaranteed valid on negative-going clock edges, however; serial data can be transferred quite simply by clocking into a receiving shift register on these edges (see Figure 9).

Incorporation of this 40ns delay guarantees that the parallel (and serial) data are valid at the Logic "1" to "0" transition of the STATUS flag, permitting parallel data transfer to be initiated by the trailing edge of the STATUS signal.

NOTES
1. THE CONVERT START PULSE WIDTH IS 100ns MIN AND MUST REMAIN LOW DURING A CONVERSION. THE CONVERSION IS INITIATED BY THE "TRAILING EDGE" OF THE CONVERT COMMAND.
2. 10µs FOR 12 BITS AND 8.4µs FOR 10 BITS (AD ADC84/AD ADC85) OR 5µs FOR 12 BITS AND 4.1µs FOR 10 BITS (AD5240).
3. MSB DECISION.
4. LSB DECISION 20ns PRIOR TO THE STATUS GOING LOW.
*BIT DECISIONS.

Figure 9. Timing Diagram (Binary Code 0 1 1 0 0 1 1 1 0 1 1 0)

DIGITAL OUTPUT DATA

Both parallel and serial data from TTL storage registers are in negative true form. Parallel data output coding is complementary binary for unipolar ranges and either complementary offset binary or complementary two's complement binary, depending on whether BIT 1 (pin 12) or its logical inverse $\overline{\text{BIT 1}}$ (pin 13) is used as the MSB. Parallel data becomes valid approximately 40ns before the STATUS flag returns to Logic "0", permitting parallel data transfer to be clocked on the "1" to "0" transition of the STATUS flag.

Serial data coding is complementary binary for unipolar input ranges and complementary offset binary for bipolar input ranges. Serial output is by bit (MSB first, LSB last) in NRZ (non-return-to-zero) format. Serial and parallel data outputs change state on positive-going clock edges. Serial data is guaranteed valid 200ns after the rising clock edges, permitting serial data to be clocked directly into a receiving register on the negative-going clock edges as shown in Figure 9. There are 13 negative-going clock edges in the complete 12-bit conversion cycle, as shown in Figure 9. The first edge shifts an invalid bit into the register, which is shifted out on the 13th negative-going clock edge. All serial data bits will have been correctly transferred and be in the receiving shift register locations shown at the completion of the conversion period.

Short Cycle Input: A Short Cycle Input, pin 14, permits the timing cycle shown in Figure 9 to be terminated after any number of desired bits has been converted, permitting somewhat shorter conversion times in applications not requiring full 12-bit resolution. When 12-bit resolution is required, pin 14 is connected to +5V (pin 16). When 10-bit resolution is desired, pin 14 is connected to Bit 11 output pin 2. The conversion cycle then terminates, and the STATUS flag resets after the Bit 10 decision (t_{10} +40ns in timing diagram of Figure 9). Short Cycle pin connections and associated maximum 12-, 10- and 8-bit conversion times are summarized in Table I.

Connect Short Cycle Pin 14 To Pin:	Connect Clock Rate Control Pin 17 To	Bits	Resolution (% FSR)	AD ADC84/ AD ADC85 (AD5240) Conversion Time (μs)	Status Flag Reset
16	15	12	0.024	10 (5)	t_{12} +40ns
2	16	10	0.100	8.5 (4.1)	t_{10} +40ns
4	28	8	0.390	6.8 (3.3)	t_8 +40ns

Table I. Short Cycle Connections

INPUT SCALING

The AD ADC84/AD ADC85/AD5240 inputs should be scaled as close to the maximum input signal range as possible in order to utilize the maximum signal resolution of the A/D converter. Connect the input signal as shown in Table II. See Figure 10 for circuit detail.

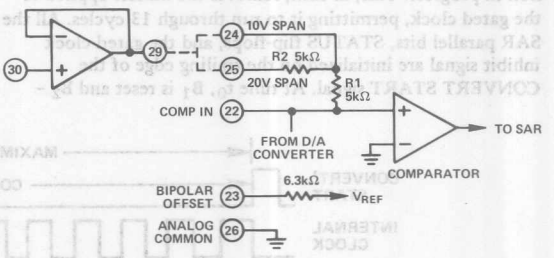


Figure 10. Input Scaling Circuit

Input Signal Range	Output Code	Connect Pin 23 To Pin	Connect Pin 25 To	For Direct Input Connect Input Signal To	For Buffered Input Pin 30 Connect Pin 29 To Pin

Table III. Input Voltages and Code Definition

CALIBRATION

External ZERO ADJ and GAIN ADJ potentiometers, connected as shown in Figures 11 and 12, are used for device calibration. To prevent interaction of these two adjustments, Zero is always adjusted first and then Gain. Zero is adjusted with the analog input near the most negative end of the analog range (0 for unipolar and -FS for bipolar input ranges). Gain is adjusted with the analog input near the most positive end of the analog range.

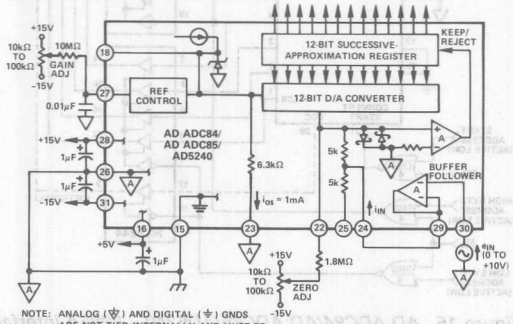

Figure 11. Analog and Power Connections for Unipolar 0 to +10V Input Range with Buffer Follower

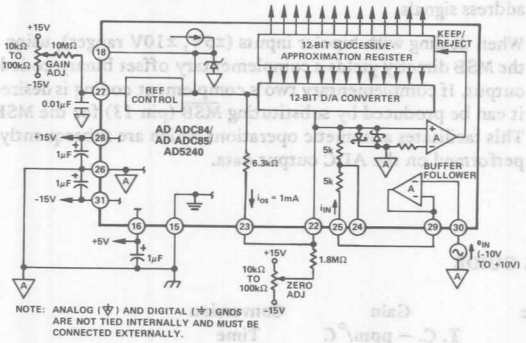

Figure 12. Analog and Power Connections for Bipolar −10V to +10V Input Range with Buffer Follower

0 to +10V Range: Set analog input to +1LSB = +0.0024V. Adjust Zero for digital output = 111111111110. Zero is now calibrated. Set analog input to +FSR -2LSB = +9.9952V. Adjust Gain for 000000000001 digital output code; full-scale (Gain) is now calibrated. Half-scale calibration check: set analog input to +5.0000V; digital output code should be 011111111111.

-10V to +10V Range: Set analog input to -9.9951V; adjust Zero for 111111111110 digital output (complementary offset binary) code. Set analog input to +9.9902V; adjust Gain for 000000000001 digital output (complementary offset binary) code. Half-scale calibration check: set analog input to 0.0000V; digital output (complementary offset binary) code should be 0111111111111.

Other Ranges: Representative digital coding for 0 to +10V and -10V to +10V ranges is given above. Coding relationships and calibration points for 0 to +5V, -2.5V to +2.5V and -5V to +5V ranges can be found by halving the corresponding code equivalents listed for the 0 to +10V and -10V to +10V ranges, respectively.

Zero and full-scale calibration can be accomplished to a precision of approximately ±1/4LSB using the static adjustment procedure described above. By summing a small sine or triangular-wave voltage with the signal applied to the analog input, the output can be cycled through each of the calibration codes of interest to more accurately determine the center (or end points) of each discrete quantization level.

GROUNDING

Many data-acquisition components have two or more ground pins which are not connected together within the device. These "grounds" are usually referred to as the Logic Power Return, Analog Common (Analog Power Return), and Analog Signal Ground. These grounds must be tied together at one point, usually at the system power-supply ground. Ideally, a single solid ground would be desirable. However, since current flows through the ground wires and etch stripes of the circuit cards, and since these paths have resistance and inductance, hundreds of millivolts can be generated between the system ground point and the ground pin of the AD ADC84/AD ADC85/AD5240. Separate ground returns should be provided to minimize the current flow in the path from sensitive points to the system ground point. In this way supply currents and logic-gate return currents are not summed into the same return path as analog signals where they would cause measurement errors.

Each of the AD ADC84/AD ADC85/AD5240's supply terminals should be capacitively decoupled as close to the device as possible. A large value capacitor such as 1μF in parallel with a 0.1μF capacitor is usually sufficient. Analog supplies are bypassed to the Analog Power Return pin and the logic supply is bypassed to the Logic Power Return pin.

CLOCK RATE CONTROL ALTERNATE CONNECTIONS

If adjustment of the CLOCK RATE is desired for faster conversion speeds, the CLOCK RATE CONTROL may be connected to an external multi-turn trim potentiometer with a TCR of ±100ppm/°C or less as shown in Figures 13 and 14. If the potentiometer is connected to -15V, conversion time can be increased as shown in Figures 4a and 4b. If these adjustments are used, delete the connections shown in Table I for pin 17. See Figures 1a and 1b for nonlinearity error vs. conversion speed and Figures 4a and 4b for the effect of the control voltage on clock speed.

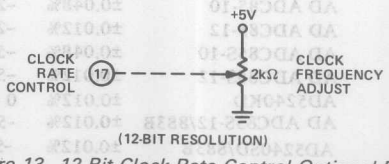

Figure 13. 12-Bit Clock Rate Control Optional Fine Adjust

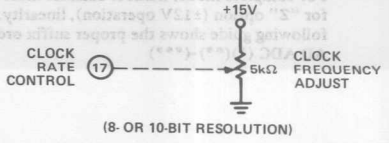

Figure 14. 8-Bit Clock Rate Control Optional Fine Adjust

MICROPROCESSOR INTERFACING

The fast conversion times of the AD ADC84/AD ADC85 and AD5240 suggest several different methods of interface to microprocessors. In systems where the ADC is used for high sampling rates on a single signal which is to be digitally processed, CPU-controlled conversion may be inefficient due to the slow cycle times of most microprocessors. It is generally preferable to perform conversions independently, inserting the resultant digital data directly into memory. This can be done using direct memory access (DMA) which is totally transparent to the CPU. Interface to user-designed DMA hardware is facilitated by the guaranteed data validity on the falling edge of the EOC signal.

Clearly, 12 bits of data must be broken up for interface to an 8-bit wide data bus. There are two possible formats: right-justified and left-justified. In a right-justified system, the least-significant 8 bits occupy one byte and the four MSB's reside in the low nybble of another byte. This format is useful when the data from the ADC is being treated as a binary number between 0 and 4095. The left-justified format supplies the eight most-significant bits in one byte and the 4LSB's in the high nybble of another byte. The data now represents the fractional binary number relating the analog signal to the full-scale voltage. An advantage to this organization is that the most-significant eight bits can be read by the processor as a coarse indication of the true signal value. The full 12-bit word can then be read only when all 12 bits are needed. This allows faster and more efficient control of a process.

Figure 15 shows a typical connection of an 8085-type bus, using a left-justified data format for unipolar inputs. Status polling is optional, and can be read simultaneously with the 4LSBs. If it is desired to right-justify the data, pins 1 through 12 of the AD ADC84/AD ADC85/AD5240 should be reversed,

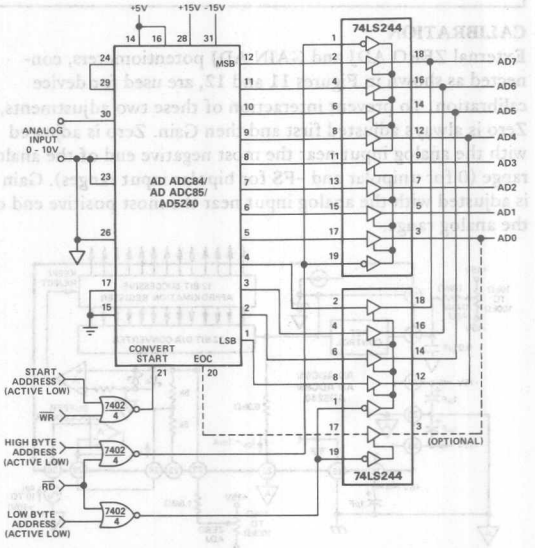

Figure 15. AD ADC84/AD ADC85/AD5240 – 8085A Interface Connections

as well as the connections to the data bus high and low byte address signals.

When dealing with bipolar inputs (±5V, ±10V ranges), using the MSB directly yields a complementary offset binary-coded output. If complementary two's complement coding is desired, it can be produced by substituting $\overline{\text{MSB}}$ (pin 13) for the MSB. This facilitates arithmetic operations which are subsequently performed on the ADC output data.

ORDERING GUIDE

Model[1]	Linearity	Temperature Range	Gain T. C. – ppm/°C	Conversion Time
AD ADC84-10	±0.048%	0 to +70°C	±30	10μs
AD ADC84-12	±0.012%	0 to +70°C	±30	10μs

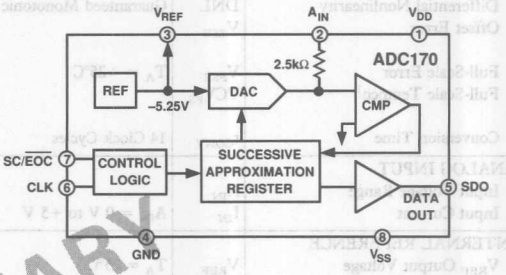
AD5240SD/883B	±0.012%	-55°C to +125°C	±25	5μs

[1] For complete model number suffixes must be added for "Z" option (±12V operation), linearity. The following guide shows the proper suffix order.
AD ADC (*)(**)-(***)

*Model Number	Typical Part Numbers
**"Z" Version Designator	AD ADC84-12
***Linearity	AD ADC85SZ-12
	AD5240ZKD



Complete, Serial-Out 5.6 µs, 12-Bit A/D Converter

ADC-170

FEATURES
8-Pin Mini-DIP Package
Fast Conversion Time—5.6 µs
Low Power—135 mW typical
Internal Low Drift Bandgap Reference
0 to +5 V Analog Input Range
3-Wire Signal Interface

APPLICATIONS
Data Acquisition Systems
Medical Diagnostics
Avionic and Navigation Systems
Process Control Equipment
Multichannel Analog I/O
Isolated Industrial Data Acquisition

FUNCTIONAL BLOCK DIAGRAM

PRELIMINARY TECHNICAL DATA

GENERAL DESCRIPTION

The ADC-170 is a complete, serial-output, 12-bit analog-to-digital converter with voltage reference, all in a space-saving 8-pin mini-DIP or 16-pin surface mount SOIC package. Operating from an external 2.5 MHz (max) clock, input signals of up to 5 V are digitized at a 5.6 µs rate. A TTL-compatible three-wire serial interface transfers the digital output data directly to the serial port of the host processor, or easily interfaces with opto isolators or transformers for high voltage isolation.

Fabricated in a complementary bipolar CMOS (CBCMOS) process, the ADC-170 utilizes a successive approximation architecture with a high speed DAC and low noise PNP-input comparator to achieve both high speed and low power operation. Operating from +5 V and −12 V to −15 V supplies, power consumption is only 135 mW. The internal voltage reference is a low drift bandgap which maintains guaranteed accuracy over the full operating temperature range of the device.

Following a start of conversion pulse, the MSB of the new digital word is available at the serial data output after 2 clock cycles, during which the new conversion results are read with the remaining 12 clock cycles. The ADC-170 can be configured for single conversion or continuous operation.

The ADC-170 provides the most complete 12-bit ADC solution available in a compact package. When combined with the serial-input DAC-8043 in the 8-pin mini-DIP package, the result is an unusually dense, high performance analog input/output port.

The ADC-170 is available in 8-pin plastic and Cerdip packages, while the SOIC-16 addresses surface mount applications. All parts are offered in the extended industrial temperature range (−40°C to +85°C). For −55°C to +125°C applications, contact your local Analog Devices sales office to obtain the ADC-170/883 data sheet.

NOTES
[1]Guaranteed by design, not subject to test.
[2]Specified performance with −12 V supply is guaranteed by testing offset and full-scale errors.
[3]Timing specifications are sample tested at +25°C to ensure compliance. All input control signals are specified with t_R = t_F = 5 ns (10% to 90% of +5 V) and timed from a voltage level of +1.6 V.

Specifications subject to change without notice.

PRELIMINARY TECHNICAL DATA

This information applies to a product under development. Its characteristics and specifications are subject to change without notice. Analog Devices assumes no obligation regarding future manufacture unless otherwise agreed to in writing.

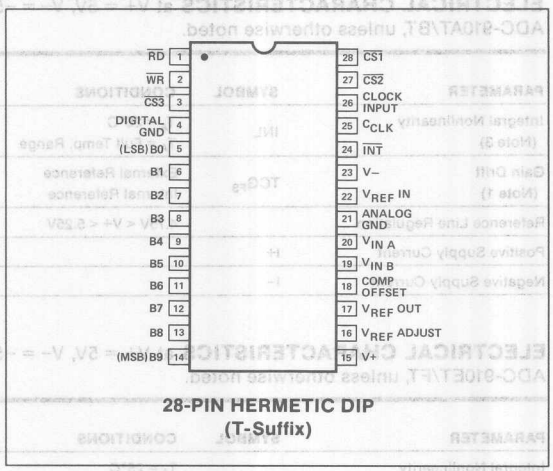
ADC-910

FEATURES

- Includes Clock, Reference, 3-State Buffered Outputs
- Fast Conversion Time 6μs
- Four Input Ranges . . +/−2.5V, +/−5.0V, +5.0V and +10.0V
- 1/2 LSB INL
- No Missing Codes Over Temperature
- Low ESD Sensitivity Due to Rugged Bipolar Processing
- Software Programmable Unipolar/Bipolar
- Easily Interfaced to 8 and 16-Bit μP Bus
- Available in Die Form

ORDERING INFORMATION†

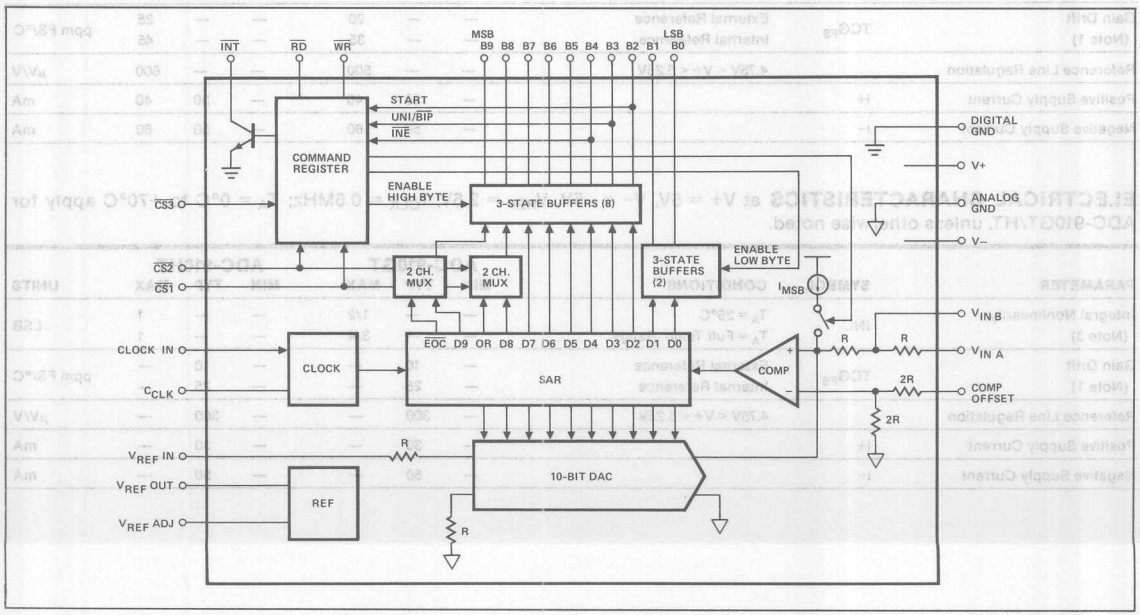
PMI MODEL NO.	TEMPERATURE RANGE
ADC910AT* ADC910BT*	−55°C/+125°C
ADC910ET ADC910FT	−25°C/+85°C
ADC910GT ADC910HT	0°C/+70°C



* For devices processed in total compliance to MIL-STD-883, add /883 after part number. Consult factory for 883 data sheet.

† Burn-in is available on commercial and industrial temperature range parts in CerDIP, plastic DIP, and TO-can packages.

GENERAL DESCRIPTION



The ADC-910 is a 10-bit A/D converter designed specifically for interfacing with microprocessors. 3-state data outputs allow direct connection to an 8-bit data bus in an MSB byte of 8 bits and an LSB byte of 2 bits. A command register with read/write inputs and 3 Chip Select inputs to control the 10 data lines is included. Interrupt enable, start conversion and bipolar/unipolar mode selection are controlled by the data bus. The use of high-speed Linear Differential Logic results in fast (6μs) conversion time and low power dissipation.

APPLICATIONS INFORMATION

CIRCUIT OPERATION (Refer to the Simplified Schematic)

The ADC-910 uses a successive approximation type A/D conversion routine. When a start command is received by the command register, the SAR, DAC and comparator begin a bit-by-bit trial against the analog input voltage. When all ten bits have been tried, the ten data outputs of the SAR will contain a 10-bit digital representation of the analog input voltage.

When the conversion is complete, a read command and a chip selection will output the data through the 3-state output buffers. Selecting CS1 will output the eight MSBs (the high byte) and selecting CS2 will output the two LSBs (the low byte). Selecting both CS1 and the CS2 will cause all ten data bits to be output through the 3-state output buffers.

When the conversion is complete, the SAR sends an end of conversion (EOC) signal to the command register, which ($\overline{INT}$), providing the interrupt disable bit ($\overline{INE}$) is set to "0". The EOC signal is also multiplexed into the input of the 3-state buffer for bit 9 (B9). Also, at this time, the overrange signal appears at the SAR output and is multiplexed into the input of the 3-state buffer for bit 8 (B8). These two bits of information comprise the status register, which is multiplexed to the data bus with a read command and a selection of $\overline{CS3}$.

Unipolar/bipolar mode selection and the enabling/disabling of the interrupt output is done when the start of conversion command is entered. In the unipolar mode, the I_{MSB} current source is turned off. For bipolar mode operation, the I_{MSB} current source is applied to the summing mode of the comparator. This provides the proper offset of I_{MSB} to do a bipolar conversion.

BASIC CONNECTIONS (Refer to Figure 1)

Power Supply Connections: The ADC-910 is operated on ±5 volt power supplies. +5 volts is applied to pin 15 and −5 volts is applied to pin 23. These lines should be bypassed near the device with a 0.1μF capacitor in parallel with a large value capacitor such as 10μF.

Analog and Digital Ground: Separate analog and digital grounds are provided to maintain optimum noise rejection. Care should be maintained to insure that digital switching noise is not introduced into the analog ground line. This can be accomplished by making the final ground point as close (physically and electrically) as possible to the analog ground pin of the ADC-910.

Analog Inputs: There are two analog voltage inputs to the ADC-910. $V_{IN\,A}$ (pin 20) accepts input signals between 0 volts and +10 volts in the unipolar mode and between −5 volts and +5 volts in the bipolar mode. $V_{IN\,B}$ (pin 19) accepts input signal levels between 0 volts and +5 volts in the unipolar mode and between −2.5 volts and +2.5 volts in the bipolar mode. The input resistance is nominally 5kΩ for $V_{IN\,A}$ and 2.5kΩ for $V_{IN\,B}$. The comparator offset pin (pin 18) is left open when using $V_{IN\,A}$, and is tied to analog ground when using $V_{IN\,B}$.

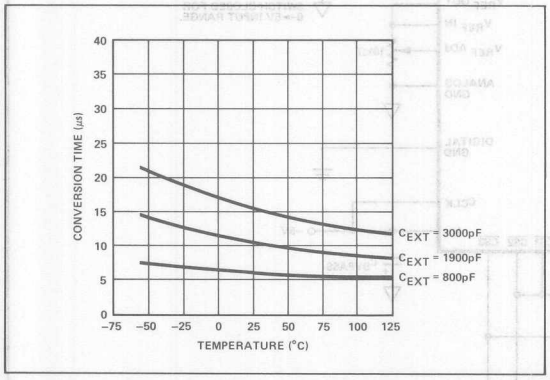
FIGURE 4: ADC-910 Timing Diagrams

Voltage Reference: The voltage reference for the ADC-910 is nominally +2.5 volts. To use this internal reference, the reference output pin (pin 17) should be tied to the reference input pin (pin 22). Adjustment of the reference voltage may be done by applying a 10kΩ trimmer between the reference output and analog ground with the center tap wiper tied to the reference adjust pin (pin 16).



To use an external reference with the ADC-910, simply apply it to the V_{REF} input pin (pin 22). This voltage should be bypassed to analog ground with a 0.01μF capacitor.

Clock: For internal clock operation, the external capacitor (C_{CLK}) sets the conversion rate. The conversion rate graph provides the relationship of C_{CLK} and temperature to conversion rate. The C_{CLK} capacitor is connected between C_{CLK} (pin 25) and the V– supply (pin 23), see Figure 1. The clock input (pin 26) is connected to the V+ supply (pin 15). Internal clock operation exhibits a conversion time variation from device to device for a given C_{CLK}, due to capacitor and internal resistor tolerances of the basic R-C oscillator. For operation at the upper frequencies of 0.5 and 1MHz, an external clock input is recommended.

For external clock operation, no clock capacitor is required. The C_{CLK} pin (pin 25) should be tied to the –5 volt supply and the external clock is applied to the clock input (pin 26). 1.0MHz clock maximum may be used. This will result in a 6μs conversion time. Slower clock rates will result in slower conversion speeds.

$$\text{Conversion time} \approx 6 \times \frac{1}{f_{CLK}}$$

Conversion time (T_C) also depends on user supplied timing relationship between positive $\overline{WR}$ edge and negative clock edge used to reset the SAR. See Figure 4(a) t_{WC} parameter.

CHIP SELECT, READ AND WRITE INPUTS

(Refer to Figure 2)

Start Commands: To start a conversion the $\overline{WR}$ input (pin 2) must be held "low" while $\overline{CS3}$ (pin 3) is held "low" and a logic "high" is applied to bit 2 (pin 7). Another way to start a conversion is to hold $\overline{CS1}$ (pin 28) and $\overline{WR}$ (pin 2) "low" for a complete clock cycle.

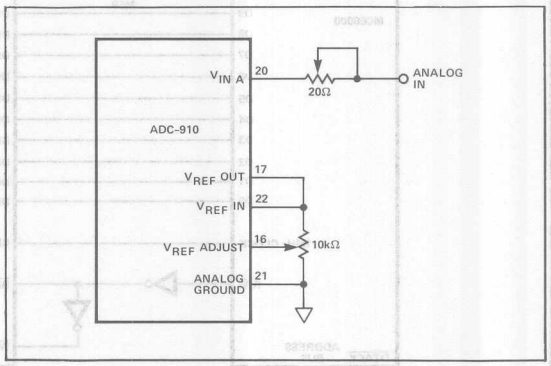
Operating mode selection is done when the start command is applied. As with the start command, $\overline{WR}$ and $\overline{CS3}$ are held "low". A logic "high" applied to bit 4 (pin 9) disables the interrupt and a logic "low" enables the interrupt. A logic "high" applied to bit 3 (pin 8) selects unipolar mode and a logic "low" selects bipolar-mode operation.

READING DATA AND CONVERSION STATUS

(Refer to Figure 3)

Data can be read in two ways: a single 10-bit word or in a 8-bit "high byte" with a 2-bit "low byte". When interfacing to a 16-bit bus, single 10-bit word reading is possible. When using an 8-bit data bus, the "high byte" and "low byte" can be multiplexed onto a single 8-bit bus as indicated in Figure 5.

To read all 10 bits at once, the RD (pin 1), CS1 (pin 28) and CS2 (pin 27) are all held "low". This turns on 3-state output buffers and all data bits can be read.



To read the 8-bit "high byte", the RD (pin 1) and CS1 (pin 28) lines are held "low".

To read the 2-bit "low byte", the RD and CS2 lines are held "low".

Included on the ADC-910 is a 2-bit status register which is multiplexed onto the data bus on lines B9 and B8.

To read the status register, RD (pin 1) and CS3 are held "low". End of conversion (EOC) is indicated by a "low" bit 9 (pin 14) and overrange (OR) is indicated by a "high" in bit 8 (pin 13).

FIGURE 5: Calibration Circuit

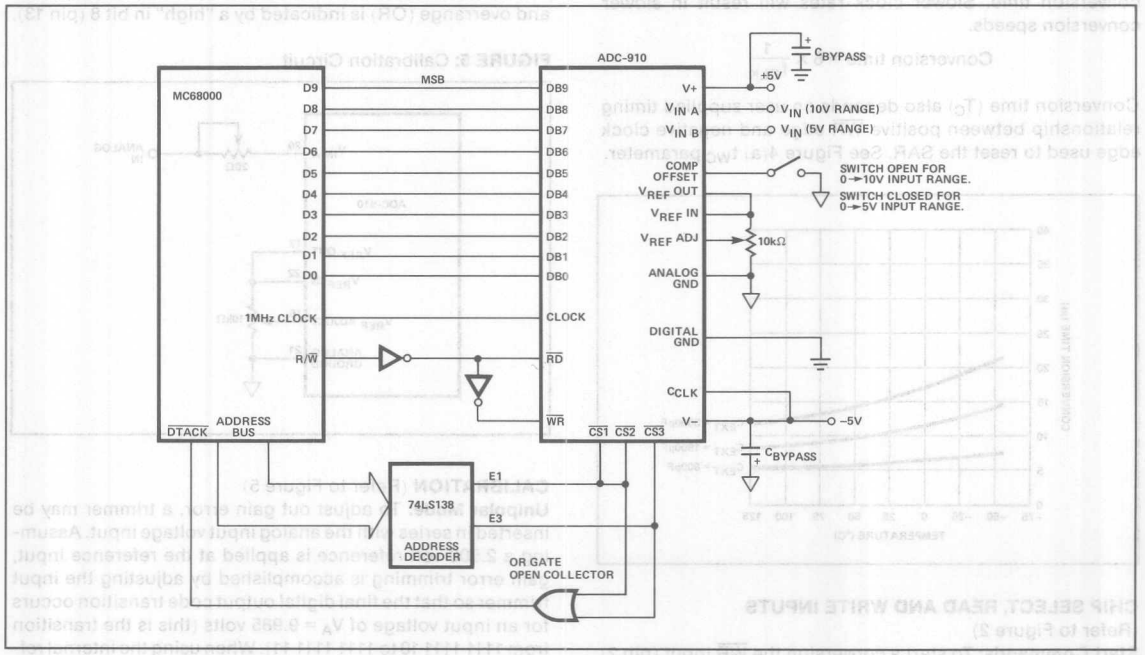
CALIBRATION (Refer to Figure 5)

Unipolar Mode: To adjust out gain error, a trimmer may be inserted in series with the analog input voltage input. Assuming a 2.500 volt reference is applied at the reference input, gain error trimming is accomplished by adjusting the input trimmer so that the final digital output code transition occurs for an input voltage of $V_A = 9.985$ volts (this is the transition from 1111 1111 10 to 1111 1111 11). When using the internal reference or an adjustable external reference, gain error trimming may be accomplished by adjusting the reference voltage until the final digital output code transition occurs at $V_A = 9.985$ volts.

Bipolar Mode: To trim out offset error, set series trimmer (if used) to 0Ω and tie $V_{IN\,A}$ to analog ground. Adjust V_{REF} to just beyond the major carry transition (that point where the digital output code changes from 0111 1111 11 to 1000 0000 00).

To trim out gain error, tie $V_{IN\,A}$ to voltage source. Adjust the series trimmer so that the final digital output code transition (from 1111 1111 10 to 1111 1111 11) occurs at an input voltage of +4.9902V.

DRIVING THE ANALOG INPUT



To insure 10-bit accuracy the input to the ADC-910 must be driven by a source which has an output impedance of less than 0.5 ohms at 1MHz.

INTERFACING THE ADC-910 TO THE MC68000

(Refer to Figure 6)

An example of a direct connection to a 16-bit data bus is shown in Figure 6. The 10-bit output of the ADC-910 is connected directly to the 10 least significant bits of the MC68000 data bus. In this example, a Motorola MC68000 Computer Board supports the 68000μP. A flow chart and assembly language program is shown below for a simplified 10-bit wide conversion.

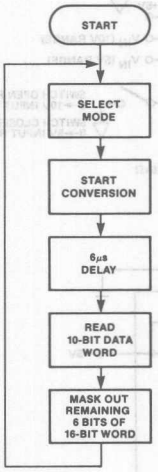


FIGURE 6: ADC-910 Interface to MC68000 Computer Board

INTERFACING THE ADC-910 TO THE 6502μP

(Refer to Figure 7)

An example of direct connection to an 8-bit data bus is shown in Figure 7. Notice that the two least significant bits are connected to data bits B3 and B4. This allows a 10-bit data transfer over an 8-bit bus. In this example, a Synertek Systems SYM-1 Educational Computer Board supports the 6502μP. The flow charts and op codes for a variety of conversion exercises are shown below.

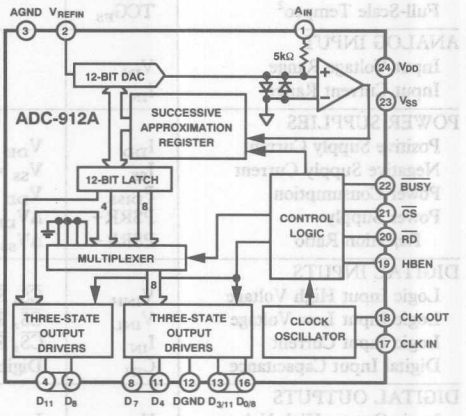
CMOS Microprocessor-Compatible 12-Bit A/D Converter

ADC-912A



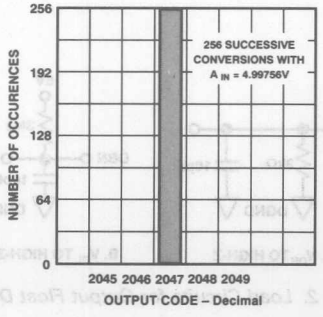
FEATURES

- Low Cost
- Low Transition Noise Between Codes
- 12-Bit Accurate
  - ±1/2 LSB Nonlinearity Error Over Temperature
  - No Missing Codes at All Temperatures
- 10 Microsecond Conversion Time
- Internal or External Clock
- 8- or 16-Bit Data Bus Compatible
- Improved ESD Resistant Design
- Latchup Resistant Epi-CMOS Processing
- Low 95 mW Power Consumption
- Space Saving 24-Pin 0.3″ DIP, or 24-Lead SOIC

APPLICATIONS

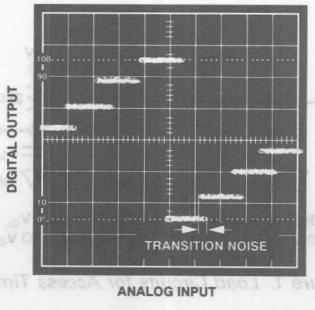
- Data Acquisition Systems
- DSP System Front End
- Process Control Systems
- Portable Instrumentation

FUNCTIONAL BLOCK DIAGRAM



GENERAL DESCRIPTION

The ADC-912A is a monolithic 12-bit accurate CMOS A/D converter. It contains a complete successive approximation A/D converter built with a high accuracy D/A converter, a precision bipolar transistor high-speed comparator, and successive approximation logic including three-state bus interface for logic compatibility. The accuracy of the ADC-912A results from the addition of precision bipolar transistors to Analog Device's advanced-oxide isolated silicon-gate CMOS process. Particular attention was paid to the reduction of transition noise between adjacent codes achieving a 1/6 LSB uncertainty. The low noise design produces the same digital output for dc analog inputs not located at a transition voltage, see the Code Repetition and Transition Noise plots below. NPN digital output transistors provide excellent bus interface timing, 125 ns access and bus disconnect time which results in faster data transfer without the need for wait states. An external 1.25 MHz clock provides a 10 μs conversion time.



In stand alone applications an internal clock can be used with external crystal.

An external negative five-volt reference sets the 0 to +10 V input range. Plus five and minus 12 volt power supplies result in 95 mW of total power consumption.

For military operating temperature range (−55°C to +125°C) versions contact your local Analog Devices sales office.

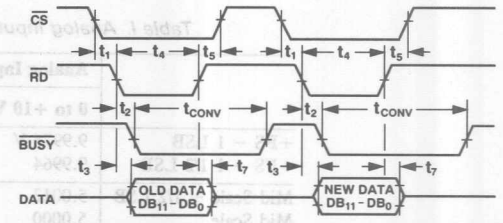
Bus Disconnect Time	t_7[4]		20	60	90	ns
HBEN to $\overline{RD}$ Setup Time	t_8		0			ns
HBEN to $\overline{RD}$ Hold Time	t_9		0			ns
Delay between Successive Read Operations	t_{10}		350	250		ns



NOTES
[1]Guaranteed by design.
[2]All input control signals are specified with $t_r = t_f$ = 5 ns (10% to 90% of +5 V) and timed from a voltage level of 1.6 V.
[3]t_3, t_4, and t_6 are measured with the load circuits of Figure 1 and timed for and output to cross 0.8 V or 2.4 V.
[4]t_7 is the time required for the data lines to change 0.5 V when loaded with the circuits of Figure 2.

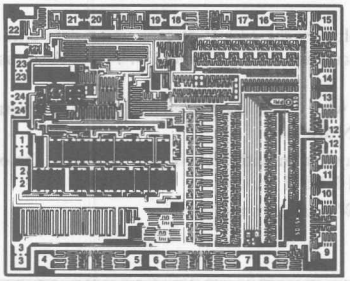
Mid Scale	5.0000	0.0000	1 0 0 0	0 0 0 0	0 0 0 0
−FS + 1/2 LSB	0.0012	−9.9976	0 0 0 0	0 0 0 0	0 0 0 ϕ
−FS	0.0000	−10.000	0 0 0 0	0 0 0 0	0 0 0 0

*The symbol "ϕ" indicates a 0 or 1 with equal probability.

CAUTION

ESD (electrostatic discharge) sensitive device. The digital control inputs are diode protected; however, permanent damage may occur on unconnected devices subject to high energy electrostatic fields. Unused devices must be stored in conductive foam or shunts. The protective foam should be discharged to the destination socket before devices are inserted.



WAFER TEST LIMITS (@ V_{DD} = +10 V, V_{SS} = −12 V or −10 V, V_{REF} = −5 V, A_{IN} = 0 V to +10 V, and T_A = 25°C, unless otherwise noted)

Parameter	Symbol	Conditions	ADC-912AG Limit	Units
Integral Nonlinearity	INL		±1	LSB max
Differential Nonlinearity	DNL		±1	LSB max
Offset Error	V_{ZSE}	Guaranteed by Design	±8	LSB max

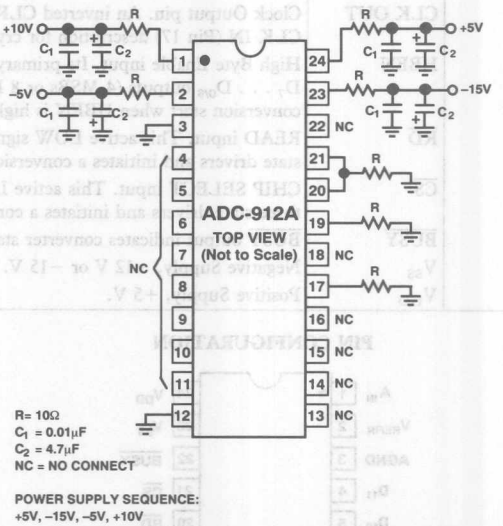
Logic Input Low Voltage	V_{INL}	$\overline{CS}$, $\overline{RD}$, HBEN	0.8	V max
Logic Input Current	I_{IN}	$\overline{CS}$, $\overline{RD}$, HBEN	±1	μA max
Logic Output High Voltage	V_{OH}	I_{SOURCE} = 0.2 mA	4	V min
Logic Output Low Voltage	V_{OL}	I_{SINK} = 1.6 mA	0.4	V max
Positive Supply Current	I_{DD}	V_{DD} = +5 V, $\overline{CS}$ = $\overline{RD}$ = V_{DD}, A_{IN} = +10 V	7	mA max
Negative Supply Current	I_{SS}	V_{SS} = −12 V, $\overline{CS}$ = $\overline{RD}$ = V_{DD}, A_{IN} = +10 V	5	mA max



NOTE
Electrical tests are performed at wafer probe to the limits shown. Due to variations in assembly methods and normal yield loss, yield after packaging is not guaranteed for standard product dice. Consult factory to negotiate specifications based on dice lot qualification through sample lot assembly and testing.

HBEN = HIGH	DB_{11}	DB_{10}	DB_9	DB_8	Low	Low	Low	Low	DB_{11}	DB_{10}	DB_9	DB_8

NOTES
*D_{11} . . . $D_{0/8}$ are the ADC data output pins.
DB_{11} . . . DB_0 are the 12-bit conversion results. DB_{11} is the MSB.

12	DGND	Digital Ground.
17	CLK IN	Clock Input pin. An external TTL compatible clock may be applied to this pin. Alternatively a crystal or ceramic resonator may be connected between CLK IN (Pin 17) and CLK OUT (Pin 18).
18	CLK OUT	Clock Output pin. An inverted CLK IN signal appears at CLK OUT when an external clock is used. See CLK IN (Pin 17) description for crystal (resonator).
19	HBEN	High Byte Enable input. Its primary function is to multiplex the 12-bits of conversion data onto the lower D_7 . . . $D_{0/8}$ outputs (4 MSBs or 8 LSBs). See pin description 4 . . . 11 and 13 . . . 16. Also disables conversion start when HBEN is high.
20	$\overline{RD}$	READ input. This active LOW signal, in conjunction with $\overline{CS}$, is used to enable the output data three-state drivers and initiates a conversion if $\overline{CS}$ and HBEN are low.
21	$\overline{CS}$	CHIP SELECT input. This active LOW signal, in conjunction with $\overline{RD}$, is used to enable the output data three-state drivers and initiates a conversion if $\overline{RD}$ and HBEN are low.
22	$\overline{BUSY}$	$\overline{BUSY}$ output indicates converter status. $\overline{BUSY}$ is LOW during conversion.
23	V_{SS}	Negative Supply, −12 V or −15 V.
24	V_{DD}	Positive Supply, +5 V.

Linearity Error vs. Conversion Time

CIRCUIT CHARACTERISTICS

The characteristic curves provide more complete static and dynamic accuracy information necessary for repetitive sampling applications often used in DSP processing. One of the important characteristic curves provided displays integral nonlinearity error (INL) versus output code with a typical value of ±1/4 LSB. Another very important characteristic associated with INL is the transition noise shown in the transition noise cross plot. The ADC-912A offers extremely small, ±1/6 LSB, transition noise which maintains the system signal-to-noise ratio in DSP processing applications. Code repetition plots show the precision internal comparator of the ADC-912A making the same decision every time for dc input voltages. Code repetition along with no missing codes assures proper performance when the ADC-912A is used in servo-control systems.

CONVERTER OPERATION DETAILS

The $\overline{CS}$, $\overline{RD}$ and HBEN digital inputs control the start of conversion. A high-to-low on both $\overline{CS}$ and $\overline{RD}$ initiate a conversion sequence. The HBEN high-byte-enable input must be low or coincident with the read $\overline{RD}$ input edge. The start of conversion resets the internal successive approximation register (SAR) and enables the three-state outputs. See Figure 8. The busy line is active low during the conversion process.

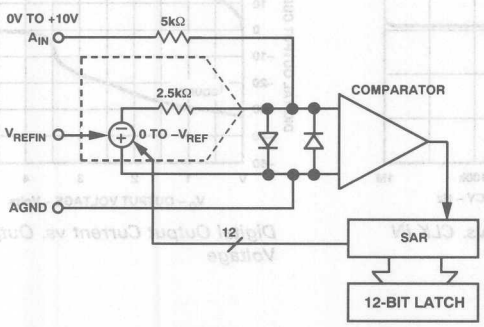

Figure 8. Simplified Analog Input Circuitry of ADC-912A

During conversion, the SAR sequences the internal voltage output DAC from the most significant bit (MSB) to the least significant bit (LSB). The analog input connects to the comparator via a 5 kΩ resistor. The DAC which has a 2.5 kΩ output resistance connects to the same comparator input. The comparator, performing a zero crossing detection, tests the addition of successively weighted bits from the DAC output versus the analog input signal. The MSB decision occurs 200 nsec after the second positive edge of the CLK IN following conversion initiation. The remaining 11-bit trials occur after the next 11 positive CLK IN edges. Once a conversion cycle is started it cannot be stopped or restarted, without upsetting the remaining bit decisions. Every conversion cycle must have 13 negative and positive CLK IN edges. At the end of conversion the comparator input voltage is zero. The SAR contains the 12-bit data word representing the analog input voltage. The $\overline{BUSY}$ line returns to logic high, signaling end of conversion. The SAR transfers the new data to the 12-bit latch.

SYNCHRONIZING START CONVERSION

Aligning the negative edge of $\overline{RD}$ with the rising edge of CLK IN provides synchronization of the internal start conversion signal to other system devices for sampling applications.

When the negative edge of $\overline{RD}$ is aligned with the positive edge of CLK IN, the conversion will take 10.4 microseconds. The minimum setup time between the negative edge of CLK IN and the negative edge of $\overline{RD}$ is 180 nanoseconds. Without synchronization the conversion time will vary from 12.5 to 13.5 clock cycles. See Figure 9.

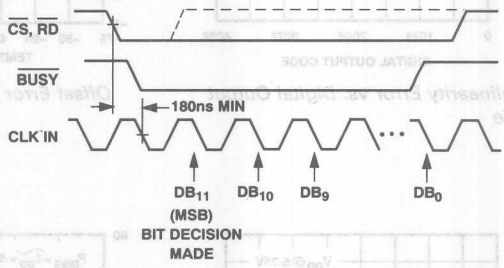

Figure 9. External Clock Input Synchronization

POWER ON INITIALIZATION

During system power-up the ADC-912A comes up in a random state. Once the clock is operating or an external clock is applied, the first valid conversion begins with the application of a high-to-low transition on both $\overline{CS}$ and $\overline{RD}$. The next 13 negative clock edges complete the first conversion producing valid data at the digital outputs. This is important in battery operated systems where power supplies are shut down between measurement times.

DRIVING THE ANALOG INPUT

During conversion, the internal DAC output current modulates the analog input current at the CLK IN frequency of 1.25 MHz. The analog input to the ADC-912A must not change during the conversion process. This requires an external buffer with low output impedance at 1.25 MHz. Suitable devices meeting this requirement include the OP-27, OP-42, and the SMP-11.

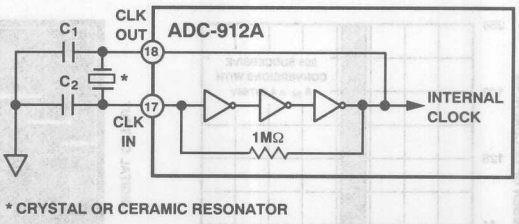

Figure 10. ADC-912A Simplified Internal Clock Circuit

INTERNAL CLOCK OSCILLATOR

Figure 10 shows the ADC-912A internal clock circuit. The clock oscillates at the external crystal or ceramic resonator frequency. The 1.25 MHz crystal or ceramic resonator connects between the CLK IN (Pin 17) and the CLK OUT (Pin 18). Capacitance values (C1, C2) depend on the crystal or ceramic resonator manufacturer. The crystal vendors should be qualified due to variations in C1 and C2 values required from vendor to vendor. Typical values range from 30 pF to 100 pF.

EXTERNAL CLOCK INPUT

A TTL compatible signal connected to CLK IN provides proper converter clock operation. No connection is necessary to the CLK OUT pin. The duty cycle of the external clock input can vary from 45% to 55%. Figure 9 shows the important waveforms.

EXTERNAL REFERENCE

A low output resistance, negative five volt reference is necessary. The external reference should be able to supply 3 mA of reference current. A bypass capacitor is necessary on the reference input lead to minimize system noise as the internal DAC switches. The reference input to the internal DAC is code dependent requiring anywhere from zero to 3 mA. The reference voltage tolerance has a direct influence on A/D converter full-scale voltage, and the maximum input full-scale voltage equals $2 \times -V_{REF}$. The ADC-912A is designed for ratiometric operation, but operation using reference voltages between −5.00 V and 0 V will result in degraded linearity performance. Integral linearity is fully tested and guaranteed for references of −5 V. Figure 11 provides a good negative five volt reference that does not require precision resistors.

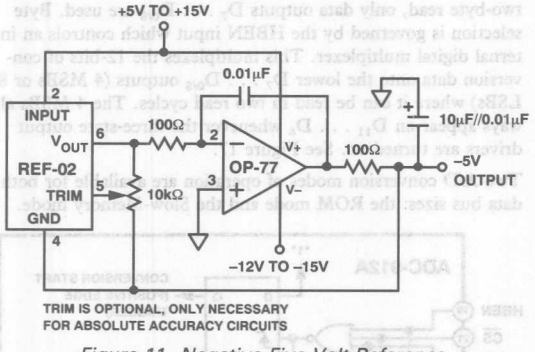

Figure 11. Negative Five Volt Reference

UNIPOLAR ANALOG INPUT OPERATION

Figure 12 shows the ideal input/output characteristic for the 0 V to 10 V input range of the ADC-912A. The designed output-code transitions occur midway between successive integer LSB values (i.e., 0.5 LSB, 1.5 LSBs, 2.5 LSBs . . . FS − 1.5 LSBs). The output code is natural binary with 1 LSB = FS/4096 = (10/4096) V = 2.44 mV. The maximum full-scale input voltage is (10 × 4095/4096) V = 9.9976 V.

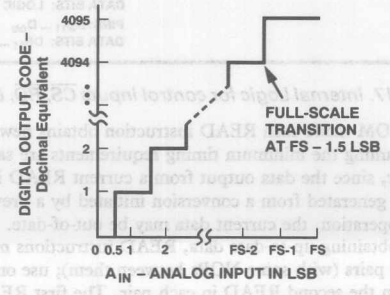

Figure 12. Ideal ADC-912A Input/Output Transfer Characteristic

OFFSET AND FULL-SCALE ERROR ADJUSTMENT, UNIPOLAR OPERATION

For applications where absolute accuracy is important offset and full-scale errors can be adjusted to zero. Figure 13 shows the extra components required for full-scale error adjustment. Zero offset is achieved by adjusting the null offset of the op amp driving A_{IN}.

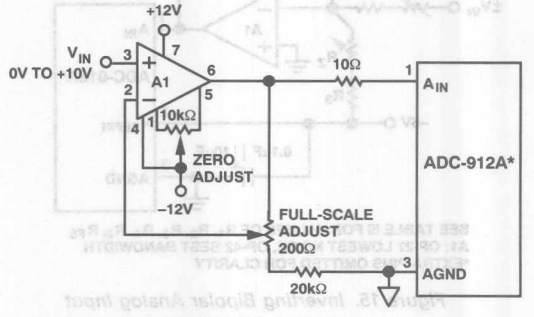

Figure 13. Unipolar 0 V to + 10 V Operation

Adjust the zero scale first by applying 1.22 mV (equivalent to 0.5 LSB input) to V_{IN}. Adjust the op amp offset control until the digital output toggles between 0000 0000 0000 and 0000 0000 0001. The next step is adjustment of full scale. Apply 9.9963 V (equivalent to FS −1.5 LSB) to V_{IN} and adjust R1 until the digital output toggles between 1111 1111 1110 and 1111 1111 1111.

BIPOLAR ANALOG INPUT OPERATION

Bipolar analog input operation is achieved with an external amplifier providing an analog offset. Figures 14 and 15 show two circuit topologies that result in different digital-output coding. In Figure 14, offset binary coding is produced when the external amplifier is connected in the inverting mode. Figure 16 shows the ideal transfer characteristics for both the inverting and non-inverting configurations given in Figures 14 and 15.

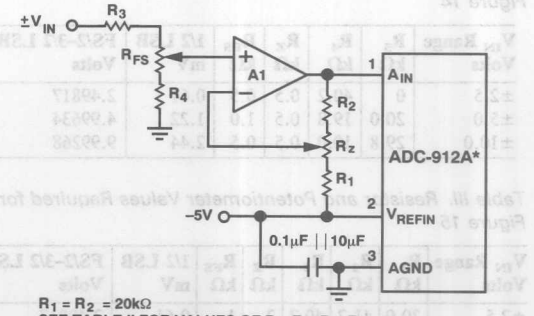

Figure 14. Noninverting Bipolar Analog Input Operation

The scaling resistors chosen in bipolar input applications should be from the same manufacturer to obtain good resistor tracking

performance over temperature. When potentiometers are used for absolute adjustment, 0.1% tolerance resistors should still be used as shown in Figures 14 and 15 to minimize temperature coefficient errors.

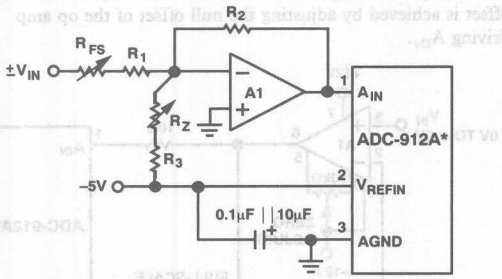

Figure 15. Inverting Bipolar Analog Input

Calibration of the bipolar analog input circuits (Figures 14 and 15) should begin with zero adjustment first. Apply a +1/2 LSB analog input to A_{IN}, (see Tables II and III) and adjust R_Z until the successive digital output codes flicker between the following codes:

For noninverting, Figure 14	1000 0000 0000 1000 0000 0001
For inverting, Figure 15	0111 1111 1111 0111 1111 1110

Next, adjust full scale by applying a FS–3/2 LSB analog input to A_{IN}, (see Tables II and III) and adjust R_{FS} until the successive digital output codes flicker between the following codes:

For noninverting, Figure 14	1111 1111 1110 1111 1111 1111
For inverting, Figure 15	0000 0000 0001 0000 0000 0000

Table II. Resistor and Potentiometer Values Required for Figure 14

V_{IN} Range Volts	R_3 kΩ	R_4 kΩ	R_Z kΩ	R_{FS} kΩ	1/2 LSB mV	FS/2–3/2 LSB Volts

MICROPROCESSOR INTERFACING

The ADC-912A has self-contained logic for both 8-bit and 16-bit

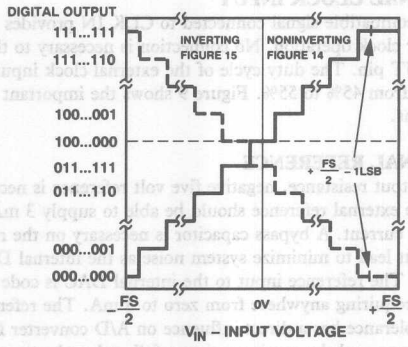

Figure 16. Ideal Input/Output Transfer Characteristics for Bipolar Input Circuits

data bus interfacing. The output data can be formatted into either a 12-bit parallel word for a 16-bit data bus or an 8-bit data word pair for an 8-bit data bus. Data is always right justified, i.e., LSB is the most right-hand bit in a 16-bit word. For a two-byte read, only data outputs $D_7 \ldots D_{0/8}$ are used. Byte selection is governed by the HBEN input which controls an internal digital multiplexer. This multiplexes the 12-bits of conversion data onto the lower $D_7 \ldots D_{0/8}$ outputs (4 MSBs or 8 LSBs) where it can be read in two read cycles. The 4 MSBs always appear on $D_{11} \ldots D_8$ whenever the three-state output drivers are turned on. See Figure 17.

Two A/D conversion modes of operation are available for both data bus sizes: the ROM mode and the Slow-Memory mode.

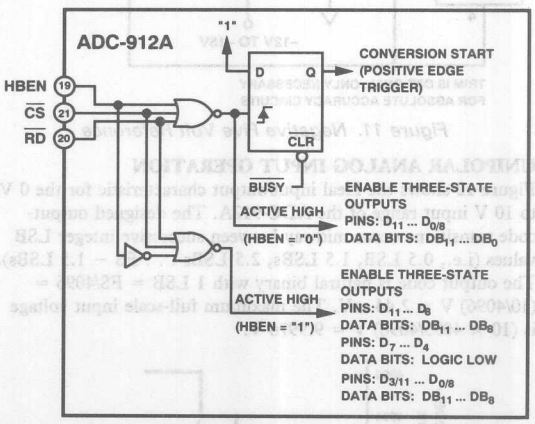

Figure 17. Internal Logic for control Inputs $\overline{CS}$, $\overline{RD}$, & HBEN

In the ROM mode each READ instruction obtains new, valid data assuming the minimum timing requirements are satisfied. However, since the data output from a current READ instruction was generated from a conversion initiated by a previous READ operation, the current data may be out-of-date. To be sure of obtaining up-to-date data, READ instructions may be coded in pairs (with some NOPs between them); use only the data from the second READ in each pair. The first READ starts the conversion, the second READ gets the results.

The Slow-Memory mode is the simplest mode. It is the method of choice where compact coding is essential, or where software bugs are a hazard. In this mode, a single READ instruction will initiate a data conversion, interrupt the microprocessor until completion (WAIT states are introduced), then read the results. If the system throughput tolerates WAIT states, and the hardware is correct, then the Slow-Memory mode is virtually immune to subsequent software modifications. Placing the microprocessor in the WAIT state has an additional advantage of quieting the digital system to reduce noise pickup in the analog conversion circuitry. The 12-bit parallel Slow-Memory mode provides the fastest analog sampling rate combined with digital data transfer rate for sampled-data systems.

PARALLEL READ, SLOW-MEMORY MODE (HBEN = LOW)

Figure 3 shows the timing diagram and data bus status for Parallel Read, Slow-Memory Mode. $\overline{CS}$ and $\overline{RD}$ going low triggers a conversion and the ADC-912A acknowledges by taking $\overline{BUSY}$ low. Data from the previous conversion appears on the three-state data outputs. $\overline{BUSY}$ returns high at the end of conversion, when the output latches have been updated, and the conversion result is placed on data outputs D_{11} . . . $D_{0/8}$.

TWO-BYTE READ, SLOW-MEMORY MODE

For a two-byte read only the 8 data outputs D_7 . . . $D_{0/8}$ are used. Conversion start procedure and data output status for the first read operation is identical to Parallel Read, Slow-Memory Mode. See Figure 4, Timing Diagram and Data Bus Status. At the end of conversion, the low data byte (D_{B7} . . . D_{B0}) is read from the A/D converter. A second READ operation with HBEN high places the high byte on data outputs $D_{3/11}$ . . . $D_{0/8}$ and disables conversion start. Note the 4 MSBs also appear on data outputs D_{11} . . . D_8 during these two READ operations.

PARALLEL READ, ROM MODE (HBEN = LOW)

A conversion is started with a READ operation. The 12 bits of data from the previous conversion are available on data outputs D_{11} . . . $D_{0/8}$ (see Figure 5). This data may be disregarded if not required. A second READ operation reads the new data (DB_{11} . . . DB_0) and starts another conversion. A delay at least as long as the ADC-912A conversion time must be allowed between READ operations. If a READ takes place prior to the end of 13 CLKS of the ADC conversion, the remaining bits not yet tested will be invalid.

TWO-BYTE READ, ROM MODE

For a two-byte read only the data outputs D_7 . . . $D_{0/8}$ are used. Conversion is started in the same way with a READ operation and the data output status is the same as the Parallel Read, ROM Mode. See Figure 6, Two-Byte Read Timing Diagram. Two more READ operations are required to obtain the new conversion result. A delay equal to the ADC-912A conversion time must be allowed between conversion start and places the high byte (4 MSBs) on data outputs $D_{3/11}$ . . . $D_{0/8}$. A third READ operation accesses the low data byte (D_{B7} . . . D_{B0}) and starts another conversion. The 4 MSBs also appear on data outputs D_{11} . . . D_8 during all three read operations above.

CIRCUIT LAYOUT GUIDELINES

As with any high speed A/D converters good circuit layout practice is essential. Wire-wrap boards are not recommended due to stray pickup of the high frequency digital noise. A PC board offers the best results. Digital and analog grounds should be separated even if they are ground planes instead of ground traces. Don't lay digital traces adjacent to high impedance analog traces. Avoid digital layouts that radiate high frequency clock signals, i.e., don't lay out digital signal lines and ground returns in the shape of a loop antenna. Shield the analog input if it comes from a different PC board source. Set up a single point ground at AGND (Pin 3) of the ADC-912A; tie all other analog grounds to this point. Also tie the logic power supply ground, but no other digital grounds, to this point (see Figure 18). Low impedance analog and digital power supply common returns are essential to low noise operation of the ADC. Their trace widths should be as wide as possible. Good power supply bypass capacitors located near the ADC package insures quiet operation. Place a 10 μF capacitor in parallel with a 0.01 μF ceramic capacitor across V_{DD} to ground and V_{SS} to ground (near Pin 3).

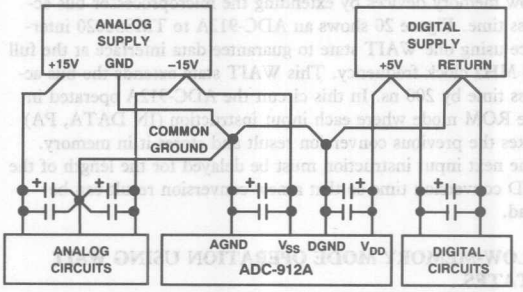

Figure 18. Power Supply Grounding

In applications where the ADC-912A data outputs and control signals are connected to a continuously active microprocessor bus, it is possible to get LSB level errors in conversion results. These errors are due to a feedthrough from the microprocessor to the internal comparator. The problem can be minimized by forcing the microprocessor into a WAIT state during conversion (see Slow-Memory microprocessor interfacing). An alternate method is isolation of the data bus with three-state buffers, such as the 74HC541.

INTERFACING TO THE TMS32010 DSP PROCESSOR

Figure 19 shows an ADC-912A to TMS32010 interface. The ADC-912A is operating in the ROM mode. The interface is designed for the maximum TMS32010 clock frequency of 20 MHz.

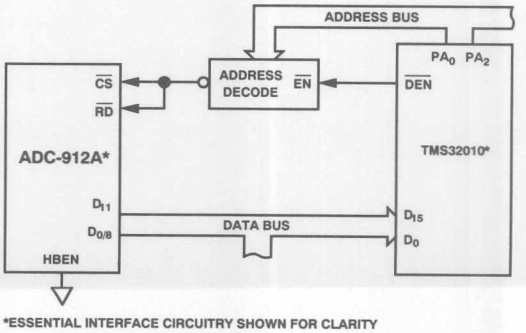

Figure 19. ADC-912A to TMS32010 DSP Processor Interface

The ADC-912A is mapped at a user-selected port address (PA). The following I/O instruction starts a conversion and reads the previous conversion into the data memory:

IN DATA, PA PA = Port Address

DATA = Data Memory Location

When conversion is complete, a second I/O instruction reads the new data into the data memory and starts another conversion. Sufficient A/D conversion time must be allowed between I/O instructions. The very first data read after system power-up should be discarded.

USING WAIT STATES

The TMS32020 DSP processor has the added capability of WAIT states. This feature simplifies the hardware required for slow memory devices by extending the microprocessor bus access time. Figure 20 shows an ADC-912A to TMS32020 interface using one WAIT state to guarantee data interface at the full 20 MHz clock frequency. This WAIT state extends the bus access time by 200 ns. In this circuit the ADC-912A operated in the ROM mode where each input instruction (IN DATA, PA) takes the previous conversion result and stores it in memory. The next input instruction must be delayed for the length of the A/D conversion time so that a new conversion result can be read.

SLOW-MEMORY MODE OPERATION USING WAIT STATES

The WAIT state feature of the TMS32020 can also be used to operate the ADC-912A in the Slow-Memory mode. This is accomplished by driving the clock input of the 7474 flip-flop in Figure 20, from the $\overline{BUSY}$ output of the ADC-912A, instead of the CLK OUT 1 of the TMS32020. Once a conversion has started the READY input of the TMS32020 is not released until the ADC-912A completes its 12-bit A/D conversion. This stops the TMS32020 during the conversion process reducing microprocessor system noise generation. Another advantage for the system software is the single instruction IN MEM, PA used to start, process, and read the results of the A/D conversion. This makes the software code more transportable between systems operating at different clock speeds. The disadvantage is some loss in instruction processing time.

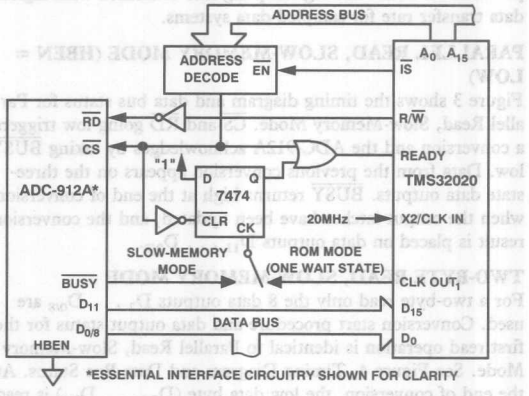

Figure 20. ADC-912A to TMS32020 Interface Using Wait States

Low Cost, 16-Bit Analog-to-Digital Converter

ADC1140

FEATURES

- Guaranteed Nonlinearity: ±0.003% FSR max
- 35μs Maximum Conversion Time
- Small Size 2″ × 2″ × 0.4″
- Wide Power Supply Operation: ±12V to ±17V

APPLICATIONS

- Process Control Data Acquisition
- Seismic Data Acquisition
- Nuclear Instrumentation
- Medical Instrumentation
- Pulse Code Modulation Telemetry
- Industrial Scales
- Robotics

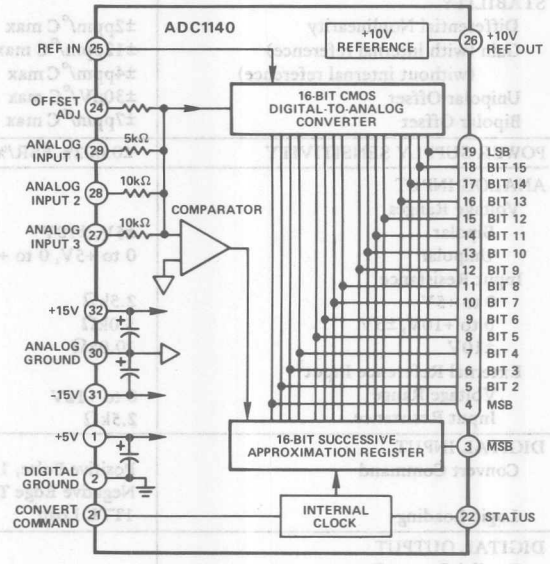
GENERAL DESCRIPTION

The ADC1140 is a low cost 16-bit successive-approximation analog-to-digital converter having a 35μs maximum conversion time. This converter provides high accuracy, high stability and low power consumption all in a 2″ × 2″ × 0.4″ module.

High accuracy performance such as integral and differential nonlinearity of ±0.003% FSR max are both guaranteed. Guaranteed stability such as differential nonlinearity TC of ±2ppm/°C maximum, offset TC of ±30μV/°C maximum, gain TC of ±12ppm/°C maximum and power supply sensitivity of ±0.002% of FSR/% V_S are also provided by the ADC1140.

The ADC1140 makes extensive use of both integrated circuit and thin-film components to obtain excellent performance, small size and low cost. The internal 16-bit DAC incorporates Analog Devices' proprietary thin-film resistor technology and proprietary CMOS current-steering switches. A low noise reference, low power comparator and low power successive-approximation register are also used to optimize the ADC1140's design (shown in Figure 1).

FUNCTIONAL BLOCK DIAGRAM



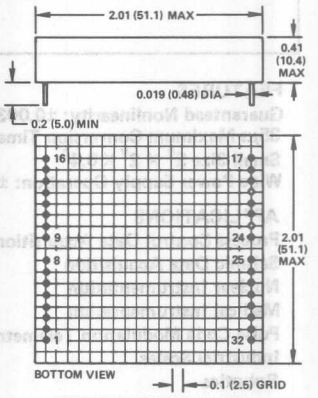


Figure 1.

The ADC1140 can operate with power supplies ranging from ±12V to ±17V and has provisions for a user supplied external reference. Four analog input voltage ranges are selectable via pin programming: ±5V, ±10V, 0 to +5V and 0 to +10V. Bipolar coding is provided in the offset binary and two's complement formats with unipolar coding displayed in true binary.

RESOLUTION	16 Bits
CONVERSION TIME	35μs max
ACCURACY[1]	
Nonlinearity Error	±0.003% FSR[2] max
Differential Nonlinearity Error	±0.003% FSR[2] max
STABILITY	
Differential Nonlinearity	±2ppm/°C max
Gain (with internal reference)	±12ppm/°C max
(without internal reference)	±4ppm/°C max
Unipolar Offset	±30μV/°C max
Bipolar Offset	±7ppm/°C max
POWER SUPPLY SENSITIVITY	±0.002% FSR/% V_S
ANALOG INPUT	
Voltage Ranges	
Bipolar	±5V, ±10V
Unipolar	0 to +5V, 0 to +10V
Input Resistance	
0 to +5V	2.5kΩ
0 to +10V, ±5V	5.0kΩ
±10V	10.0kΩ
External Reference Input[3]	
Voltage Range	0 to +12V
Input Resistance	2.5kΩ
DIGITAL INPUT	
Convert Command	Positive Pulse, 100ns Width min Negative Edge Triggered
Logic Loading	1TTL Load
DIGITAL OUTPUT	
Parallel Output Data	
Unipolar	Binary (BIN)
Bipolar	Offset Binary (OBIN) Two's Complement
Output Drive	1TTL Load
Status	Logic "1" During Conversion
Output Drive	1TTL Load
INTERNAL REFERENCE VOLTAGE	+10V, ±0.3%
External Load Current	
(Rated Performance)	2mA max
Temperature Stability	±8.5ppm/°C max
POWER REQUIREMENTS[4]	
Voltage (Rated Performance)	±15V ±3%, +5V ±3%
Voltage (Operating)	±12V to ±17V, +4.75V to +5.25V
Supply Current Drain ±15V	±25mA
+5V	150mA
TEMPERATURE RANGE	
Specified	0 to +70°C
Operating	−25°C to +85°C
Storage	−55°C to +85°C
SIZE	2" X 2" X 0.4" (51 X 51 X 10.4mm)
Weight	1.2 oz (33g)

OUTLINE DIMENSIONS

NOTES

[1] Offset and gain error are adjustable to zero by means of external potentiometers. See Figure 3 for proper connection.

[2] FSR means Full Scale Range.

[3] Rated performance is specified with +10.0V reference.

[4] Recommended Power Supply: Analog Devices Model 923.

Specifications subject to change without notice.

OPERATION

For operation, the only connections to the ADC1140 that are necessary are the power supplies, internal or external reference, input voltage pin programming, convert command and digital output. Refer to Table I for input pin programming and Figure 3 for offset and gain calibration.

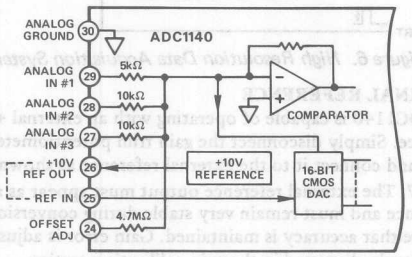

Figure 2. Analog Input Block Diagram

ANALOG INPUT PROGRAMMING

The analog input section consists of three analog input terminals. Analog input range selection is accomplished by pin programming as shown in Table I.

In the unipolar mode, a 0 to +10V or a 0 to +5V input signal develops a 0 to +2mA current that is compared to the 0 to –2mA (shown in Figure 2) current output of the DAC.

In the bipolar mode, a +1mA offset current from the reference is applied to the comparator input via pin programming connections. The ADC1140 can then accept either ±5V or ±10V inputs. These inputs again will be converted to current and compared with the DAC's 0 to –2mA current output.

Table I. Analog Input Voltage Pin Programming

Input Signal Range	Coding	Connect Input Signal To Pin(s)	Connect Pin 26 To Pin*	Connect Pin 30 To Pin(s)
±10V	OBIN, Two's Comp	28	27	29, 2
±5V	OBIN, Two's Comp	29	27	28, 2
0 to +5V	BIN	27, 28, 29	Open	2
0 to +10V	BIN	27, 28	Open	29, 2

*If Internal Reference is used, Pins 25 and 26 must be connected together through a 50Ω potentiometer or 24.9Ω fixed resistor (see Figure 3 and the gain calibration section).

OPTION OFFSET & GAIN CALIBRATION

Initial offset and gain errors can be adjusted to zero by potentiometers as shown in Figure 3. Proper offset and gain calibration requires great care and the use of an accurate and stable voltage reference. The voltage standard used as a signal source must be very stable. It should be capable of being set to within 1μV of the desired value at both ends of its range. The potentiometers selected should be of the good quality Cermet type. Multi-turn potentiometers having ten to fifteen turns and 100ppm/°C temperature coefficients will be adequate. The temperature coefficients contributed by these Cermet potentiometers will be less than 0.1ppm/°C.

By adjusting the offset first, gain and offset adjustments will remain independent of each other.

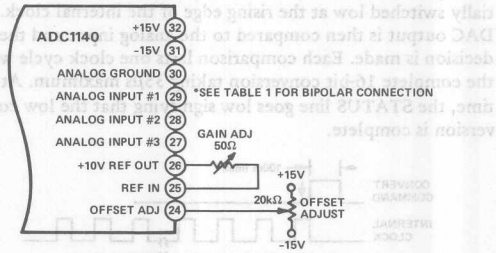

Figure 3. Offset and Gain Calibration

OFFSET CALIBRATION

For 0 to +10V range, set the input voltage precisely to +76μV; for 0 to +5V range, set it at +38μV. Adjust the zero potentiometer until the binary coded converter is just on the verge of switching from 000 . . . 00 to 000 . . . 01.

For ±5V range, set the input voltage precisely to –4.999924V; for ±10V range, set it at –9.999847V. Adjust the zero potentiometer until the offset binary coded units are just on the verge of switching from 000 . . . 00 to 000 . . . 01 and the two's comp. coded units are just on the verge of switching from 100 . . . 0 to 100 . . . 1.

GAIN CALIBRATION

Set the input voltage precisely at +9.99977V for 0 to +10V input range, +4.99977V for ±5V input range, +9.99954V for ±10V input range, or +4.99988V for 0 to +5V input range, adjust the gain potentiometer until binary and offset binary coded units are just on the verge of switching from 111 . . . 0 to 111 . . . 1 and two's comp. coded units are just on the verge of switching from 011 . . . 10 to 011 . . . 11. Note that these values are 1 1/2 LSBs less than nominal full scale.

POWER SUPPLY AND GROUNDING CONNECTIONS

The analog power ground (pin 30) and digital ground (pin 2) are not connected internally. The connection must be made externally. The choice of an optimum "star" point is an important consideration in avoiding ground loops and to minimize coupling between the analog and digital sections. One suggested approach is shown in Figure 4.

Because the ADC1140 contains high quality tantalum capacitors on each of the power supply inputs to ground, external bypass capacitors are not required.

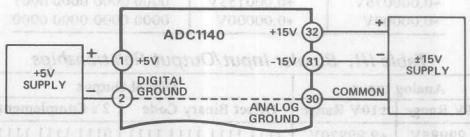

Figure 4. Power Supply and Grounding Techniques

ADC1140 TIMING

Conversion is initiated with the negative going edge of the Convert Command pulse as shown in Figure 5. The Convert Command pulse width must be a minimum of 100ns. Once the conversion process is initiated, it cannot be retriggered until after the end of conversion.

With the negative edge of the Convert Command pulse, all internal logic is reset. The MSB is set low with the remaining digitial outputs set to logic high state, and the status line is set high and remains high thru the full conversion cycle.

During conversion each bit, starting with the MSB, is sequentially switched low at the rising edge of the internal clock. The DAC output is then compared to the analog input and the bit decision is made. Each comparison lasts one clock cycle with the complete 16-bit conversion taking 35μs maximum. At this time, the STATUS line goes low signifying that the low conversion is complete.

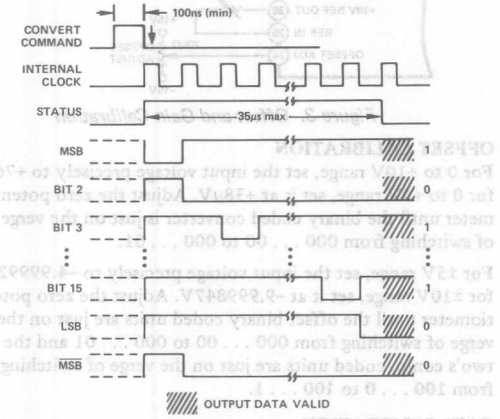

Figure 5. ADC1140 Timing Diagram

ANALOG INPUT/OUTPUT RELATIONSHIPS

The ADC1140 produces a true binary coded output when configured as a unipolar device. Configured as a bipolar device, it can produce either offset binary or two's complement output codes. The most significant bit (MSB) is displayed on pin 4 for the binary and offset binary codes or on pin 3 for the two's complement code. Table II shows the unipolar analog input/digital output relationships. Table III shows the bipolar analog input/digital output relationships for offset binary code and two's complement codes.

Table II. Unipolar Input/Output Relationships

Analog Input		Digital Output
0 to +5V Range	0 to +10V Range	Binary Code
+4.999924V	+9.99985V	1111 1111 1111 1111
+2.50000V	+5.00000V	1000 0000 0000 0000
+1.25000V	+2.50000V	0100 0000 0000 0000
+0.62500V	+1.25000V	0010 0000 0000 0000
+0.000076V	+0.000153V	0000 0000 0000 0001
+0.00000V	+0.00000V	0000 0000 0000 0000

Table III. Bipolar Input/Output Relationships

Analog Input		Digital Output	
±5V Range	±10V Range	Offset Binary Code	2's Complement Code
+4.99985V	+9.99970V	1111 1111 1111 1111	0111 1111 1111 1111
+2.50000V	+5.00000V	1100 0000 0000 0000	0100 0000 0000 0000

HIGH RESOLUTION DATA ACQUISITION SYSTEM

Shown in Figure 6 is a high resolution data acquisition system. Here the SHA1144, a high resolution sample-hold amplifier, is used to drive the ADC1140. Conversion is initiated by the negative edge of the convert command pulse. At this time the STATUS pulse goes low causing the SHA1144 to go from the sample mode to the hold mode. When the conversion is complete, 35μs later, the STATUS pulse goes low, thus placing the SHA1144 in the sample mode.

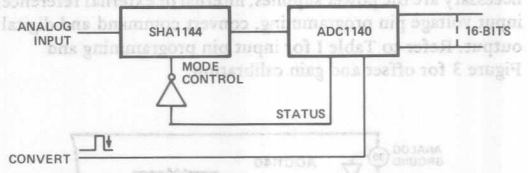

Figure 6. High Resolution Data Acquisition System

EXTERNAL REFERENCE

The ADC1140 is capable of operating with an external +10.0V reference. Simply disconnect the gain trim potentiometer from pin 26 and connect it to the external reference as shown in Figure 7. The external reference output must appear as a low impedance and must remain very stable during conversion to insure that accuracy is maintained. Gain error is adjusted as previously discussed in the gain calibration section.

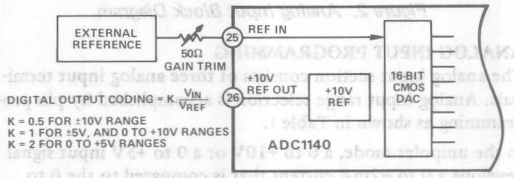

Figure 7. External Reference

The ADC1140 is factory tested and calibrated with the internal +10.0V reference voltage but nonstandard external voltages can be used with the digital output coding being determined by the formula shown in Figure 7.

PIA INTERFACE

The ADC1140 can be used with a PIA to interface directly to a microprocessor. As shown in Figure 8 the 16-bit output of the ADC1140 is split into two 8-bit bytes. Part A of the PIA is programmed to read the eight most-significant-bits while Part B reads the eight least-significant-bits. Output CB2 is used to start the ADC1140 conversion process. CB1, of the PIA, is used to sense the STATUS of the ADC1140 so that the end of conversions can be determined. The control bus, address bus, and data bus are then connected directly to the microprocessor.

With the use of PIAs, control of one or more ADC1140s can be accomplished in many different configurations.

V/F & F/V Converters

VOLTAGE-TO-FREQUENCY CONVERTERS

Voltage-to-frequency converters (VFCs) convert analog voltage or current levels to pulse trains or square waves in a logic-compatible form (usually TTL) at frequencies that are accurately proportional to the analog quantity. The output continuously tracks the input signal, responding directly to changes in the input signal; external clock synchronization is not required. V/F converters find applications in analog-to-digital converters with high resolution, long-term high-precision integrators, two-wire high-noise-immunity digital transmission and digital voltmeters.

FREQUENCY-TO-VOLTAGE CONVERTERS

Frequency-to-voltage converters (FVCs) perform the inverse operation; they accept a wide variety of periodic waveforms and produce an analog output proportional to frequency. Combining adjustable threshold, gain and output offset with low linearity error, F/V converters offer economical solutions to a wide variety of applications where it is required to convert frequency to an analog voltage. Examples are motor-speed controllers, power-line frequency monitors and VCO stabilization circuits. In analog-to-analog data transmission, they convert serially transmitted data in the form of pulse streams back to analog voltage.

Applications of both forms of conversion, as appropriate to specific device types, are illustrated with varying degrees of detail on the individual data sheets.

FACTORS IN CHOOSING VFCs AND FVCs

The charge-balance and the astable-multivibrator type architectures are two design techniques used to implement the voltage-to-frequency function. The output of a charge balance VFC is a train of pulses of constant width and height, with very low duty cycles for small analog inputs. An astable-multivibrator VFC produces a square wave for its output.

The charge-balance converter architecture used for the AD650 is shown in Figure 1. It comprises a summing integrator, a current source and steering switch, a comparator, a one-shot, and an output transistor. The input signal current may be provided directly by a current source or be generated by an input voltage across R_{IN}. This current is *exactly* balanced by an internal feedback current delivered in the form of precision pulses from the switched 1 mA internal current source. These current pulses can be thought of as precisely defined packets of charge. The required number of charge packets, each producing one pulse at the output transistor, depends upon the amplitude of the input current signal. Since the number of charge packets delivered per unit time to the summing junction is related to the input signal current amplitude by a linear function, the voltage-to-frequency transformation is achieved.

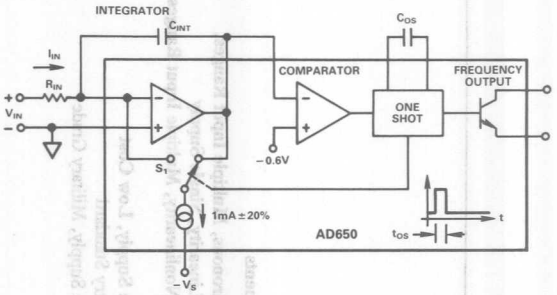

Figure 1. Block Diagram of the AD650

This architecture allows for a full-scale frequency up to 1MHz and can achieve linearity errors as low as 0.005%. Excellent noise rejection is achieved since the charge balance architecture is performing a continuous integration on the input signal. Also, it has a dynamic range of up to six decades allowing for extremely high resolution measurements. A F-V conversion may be easily implemented with this architecture. Full-scale frequency, gain error, and linearity are significantly determined by the stability, accuracy, and proper selection of the one-shot capacitor and R_{IN}.

A variation of this architecture known as a synchronous voltage-to-frequency converter is used on the AD652 shown in Figure 2. This modified charge-balance type architecture uses an external clock to define the full-scale output frequency, rather than depend on the stability of an external one-shot capacitor, therefore improving upon the temperature drift specifications. It is capable of producing a 2 MHz full-scale output and can achieve linearity errors as low as 0.002%. Also, by referencing the comparator and analog input to an on-chip 5 volt reference, the device may operate single supply.

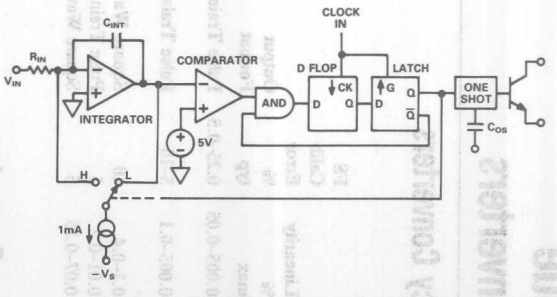

Figure 2. Block Diagram of the AD652

The astable-multivibrator architecture used on the AD654 and the AD537 is shown in Figure 3. It uses a current controlled precision multivibrator as the primary timing element. An operational amplifier converts the input voltage into a proportional unipolar current which drives the multivibrator circuit and timing capacitor through n-p-n transistors. This current determines the charging and discharging rate of the timing capacitor which in turn determines the frequency of operation of the multivibrator circuit. The frequency output is a square wave delivered via an open-collector n-p-n transistor whose emitter is returned to digital ground for high noise immunity against digital spikes.

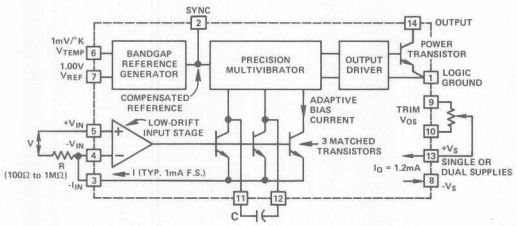

Figure 3. Block Diagram of the AD537

The power consumption of a multivibrator VFC can be very low: for example, the AD654 can operate on single supply voltages as low as 4.5 volts and consume a maximum of 3.0 mA quiescent current. The device can operate with a full-scale frequency up to 500 kHz and achieve voltage-to-frequency nonlinearity as low as 0.03%. Also, the square wave output allows it to be ac coupled without introducing dc level shifts with a change in frequency.

The frequency-to-voltage conversion may be easily implemented with the charge-balance VFCs such as the AD650 by reconfiguring it and by adding a simple logic biasing network. The device may convert frequencies up to 1 MHz to full-scale output voltages up to 10 volts. The AD652 synchronous VFC may also be configured for this function when an application requires a higher degree of linearity. The AD537 and AD654 may also be used in a F-V converter application as the oscillator in a phase locked loop when used in conjunction with a quad nand gate which serves as a phase comparator.

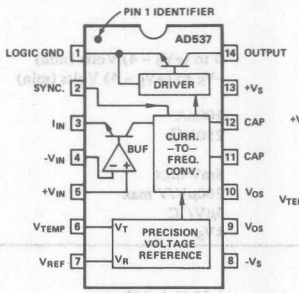
SPECIFICATIONS

The salient specifications for VFCs are *(non)linearity*, as a percentage of full-scale frequency; *frequency range*, the greater the frequency range, the greater the resolution for a given counting period; *full-scale-calibration error; gain-temperature coefficient*, in ppm of signal per °C, where "gain" is the ratio of full-scale frequency to full-scale voltage; *input-offset temperature coefficient; overrange capability*, within rated specifications, and *step response*, the worst-case time interval required for the frequency to respond to a full-scale-step input change.

For FVCs, important specs, in addition to accuracy specs corresponding to the above, include *output ripple* (for specified input frequencies), *threshold* (for recognition that another cycle has been initiated and for versatility in interfacing various types of sensors directly), *hysteresis* (to provide a degree of insensitivity to noise superimposed on a slowly-varying input waveform) and *dynamic response* (important in motor control).

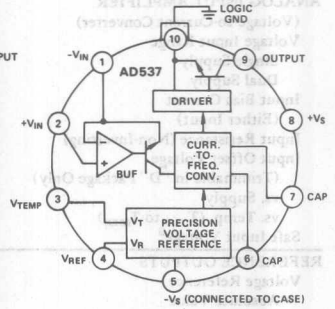
Definitions of some critical specifications, and the conditions for adjusting or measuring them, are detailed on individual data sheets.

Integrated Circuit Voltage-to-Frequency Converter



AD537*

FEATURES



- Low Cost A-D Conversion
- Versatile Input Amplifier
  - Positive or Negative Voltage Modes
  - Negative Current Mode
  - High Input Impedance, Low Drift
- Single Supply, 5 to 36 Volts
- Linearity: ±0.05% FS
- Low Power: 1.2mA Quiescent Current
- Full Scale Frequency up to 100kHz
- 1.00 Volt Reference
- Thermometer Output (1mV/K)
- F-V Applications
- F-V Applications
- MIL-STD-883 Compliant Versions Available

PIN CONFIGURATIONS

"D" Package – TO-116

"H" Package – TO-100

PRODUCT DESCRIPTION

The AD537 is a monolithic V-F converter consisting of an input amplifier, a precision oscillator system, an accurate internal reference generator and a high current output stage. Only a single external RC network is required to set up any full scale (F.S.) frequency up to 100kHz and any F.S. input voltage up to ±30V. Linearity error is as low as ±0.05% for 10kHz F.S., and operation is guaranteed over an 80dB dynamic range. The overall temperature coefficient (excluding the effects of external components) is typically ±30ppm/°C. The AD537 operates from a single supply of 5 to 36V and consumes only 1.2mA quiescent current.

A temperature-proportional output, scaled to 1.00mV/K, enables the circuit to be used as a reliable temperature-to-frequency converter; in combination with the fixed reference output of 1.00V, offset scales such as 0°C or 0°F can be generated.

The low drift (1μV/°C typ) input amplifier allows operation directly from small signals (e.g., thermocouples or strain gages) while offering a high (250MΩ) input resistance. Unlike most V-F converters, the AD537 provides a square-wave output, and can drive up to 12 TTL loads, LEDs, very long cables, etc.

The excellent temperature characteristics and long-term stability of the AD537 are guaranteed by the primary band-gap reference generator and the low T.C. silicon chromium thin film resistors used throughout.

The device is available in either a TO-116 ceramic DIP or a TO-100 metal can; both are hermetically sealed packages.

The AD537 is available in three performance/temperature grades; the J and K grades are specified for operation over the 0 to +70°C range while the AD537S is specified for operation over the extended temperature range, -55°C to +125°C.

PRODUCT HIGHLIGHTS

1. The AD537 is a complete V-F converter requiring only an external RC timing network to set the desired full scale frequency and a selectable pull-up resistor for the open-collector output stage. Any full-scale input voltage range from 100mV to 10 volts (or greater, depending on $+V_S$) can be accommodated by proper selection of timing resistor. The full scale frequency is then set by the timing capacitor from the simple relationship, f = V/10RC.
2. The power supply requirements are minimal, only 1.2mA quiescent current is drawn from a single positive supply from 4.5 to 36 volts. In this mode, positive inputs can vary from 0 volts (ground) to ($+V_S$ - 4) volts. Negative inputs can easily be connected for below ground operation.
3. F-V converters with excellent characteristic are also easy to build by connecting the AD537 in a phase-locked loop. Application particulars are shown in Figure 6.
4. The versatile open-collector NPN output stage can sink up to 20mA with a saturation voltage less than 0.4 volts. The Logic Common terminal can be connected to any level between ground (or $-V_S$) and 4 volts below $+V_S$. This allows easy direct interface to any logic family with either positive or negative logic levels.
5. The AD537 is available in versions compliant with MIL-STD-883. Refer to the Analog Devices Military Product Databook or current AD537/883B data sheet for detailed specifications.

*Protected by Patent Nos. 3,887,963 and RE 30,586.

NOTES

*Specifications same as AD537JH.

**Specifications same as AD537K.

Specifications subject to change without notice.

[1] Nonlinearity is specified for a current input level (I_{IN}) to the converter from 0.1 to 1000μA. Converter has 100% overrange capability up to I_{IN} = 2000μA with slightly reduced linearity. Nonlinearity is defined as deviation from a straight line from zero to full scale, expressed as a percentage of full scale.

[2] Guaranteed not tested.

[3] Maximum voltage input level is equal to the supply on either input terminal. However, large negative voltage levels can be applied to the negative terminal if the input is scaled to a nominal 1mA full scale through an appropriate value resistor (see Figure 2).

[4] Loading the 1.0 volt or 1mV/K outputs can cause a significant change in overall circuit performance, as indicated in the applications section. To maintain normal operation, these outputs should be operated into the external buffer or an external amplifier.

[5] Temperature reference output performance is specified from 0 to +70°C for "J" and "K" devices, –55°C to +125°C for "S" model.

[6] D = Ceramic DIP; H = Hermetic Metal Can. For outline information see Package Information section.

[7] For AD537/883B specifications, refer to Analog Devices Military Products Databook.

CIRCUIT OPERATION

Block diagrams of the AD537 are shown above. A versatile operational amplifier (BUF) serves as the input stage; its purpose is to convert and scale the input voltage signal to a drive current in the NPN follower. Optimum performance is achieved when, at the full scale input voltage, a 1mA drive current is delivered to the current-to-frequency converter. The drive current to the current-to-frequency converter (an astable multivibrator) provides both the bias levels and the charging current to the externally connected timing capacitor. This "adaptive" bias scheme allows the oscillator to provide low nonlinearity over the entire current input range of 0.1 to 2000μA. The square wave oscillator output goes to the output driver which provides a floating base drive to the NPN power transistor. This floating drive allows the logic interface to be referenced to a different level than $-V_S$. The "SYNC" input ("D" package only) allows the oscillator to be slaved to an external master oscillator; this input can also be used to shut off the oscillator.

The reference generator uses a band-gap circuit (this allows single-supply operation to 4.5 volts which is not possible with low T.C. zeners) to provide the reference and bias levels for the amplifier and oscillator stages. The reference generator also provides the precision, low T.C. 1.00 volt output and the V_{TEMP} output which tracks absolute temperature at 1mV/K.

V-F CONNECTION FOR POSITIVE INPUT VOLTAGES

The positive voltage input range is from $-V_S$ (ground in single supply operation) to 4 volts below the positive supply. The connection shown in Figure 1 provides a very high (250MΩ) input impedance. The input voltage is converted to the proper drive current at pin 3 by selecting a scaling resistor. The full scale current is 1mA, so, for example a 10 volt range would require a nominal 10kΩ resistor. The trim range required will depend on capacitor tolerance. Full scale currents other than 1mA can be chosen, but linearity will be reduced; 2mA is the maximum allowable drive.

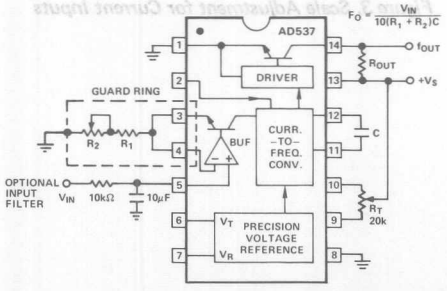

Figure 1. Standard V-F Connection for Positive Input Voltages

As indicated by the scaling relationship in Figure 1, a 0.01μF timing capacitor will give a 10kHz full scale frequency, and 0.001μF will give 100kHz with a 1mA drive current. The maximum frequency is 150kHz. Polystyrene or NPO ceramic capacitors are preferred for T.C. and dielectric absorption; polycarbonate or mica are acceptable; other types will degrade linearity. The capacitor should be wired very close to the AD537.

V-F CONNECTIONS FOR NEGATIVE INPUT VOLTAGE OR CURRENT

A wide range of negative input voltages can be accommodated with proper selection of the scaling resistor, as indicated in Figure 2. This connection, unlike the buffered positive connection, is not high impedance since the 1mA F.S. drive current must be supplied by the signal source. However, very large negative voltages beyond the supply can be handled easily; just modify the scaling resistors appropriately. Diode CR1 (HP5082-2811) is necessary for overload and latchup protection for current or voltage inputs.

If the input signal is a true current source, R_1 and R_2 are not used. Full scale calibration can be accomplished by connecting a 200kΩ pot in series with a fixed 27kΩ from pin 7 to $-V_S$ (see calibration section, below).

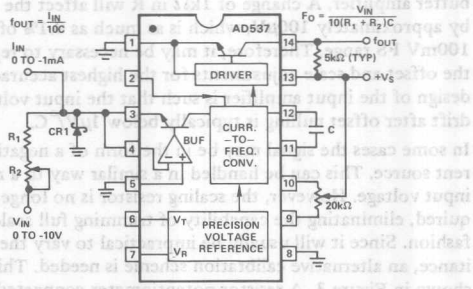

Figure 2. V-F Connections for Negative Input Voltage or Current

first is trimmed by adjustment of the scaling resistor R and the second by the (optional) potentiometer connected to $+V_S$ and the V_{OS} pins ("D" package only). Precise calibration requires the use of an accurate voltage standard set to the desired FS value and a frequency meter; a scope is useful for monitoring output waveshape. Verification of linearity requires the availability of a switchable voltage source (or a DAC) having a linearity error below ±0.005%, and the use of long measurement intervals to minimize count uncertainties. *Every AD537 is automatically tested for linearity*, and it will not usually be necessary to perform this verification, which is both tedious and time-consuming.

Although drifts are small it is good practice to allow the operating environment to attain stable temperature and to ensure that the supply, source and load conditions are proper. Begin by setting the input voltage to 1/10,000 of full scale. Adjust the offset pot until the output frequency is 1/10,000 of full scale (for example 1Hz for FS of 10kHz). This is most easily accomplished using a frequency meter connected to the output. Then apply the FS input voltage and adjust the gain pot until the desired FS frequency is indicated. In applications where the FS input is small, this adjustment will very slightly affect the offset voltage, due to the input bias current of the buffer amplifier. A change of 1kΩ in R will affect the input by approximately 100μV, which is as much as 0.1% of a 100mV FS range. Therefore, it may be necessary to repeat the offset and scale adjustments for the highest accuracy. The design of the input amplifier is such that the input voltage drift after offset nulling is typically below 1μV/°C.

In some cases the signal may be in the form of a negative current source. This can be handled in a similar way to a negative input voltage. However, the scaling resistor is no longer required, eliminating the capability of trimming full scale in this fashion. Since it will usually be impractical to vary the capacitance, an alternative calibration scheme is needed. This is shown in Figure 3. A resistor-potentiometer connected from the V_R output to $-V_S$ will alter the internal operating conditions in a predictable way, providing the necessary adjustment range. With the values shown, a range of ±4% is available; a larger range can be attained by reducing R1. This technique does not degrade the temperature-coefficient of the converter, and the linearity will be as for negative input voltages. The minimum supply voltage may be used.

selected to be 5% below the nominal value; with R2 in its mid-position the output frequency is given by

$$f = \frac{I}{10.5 \times C}$$

where f is in kHz, I is in mA and C is in μF. For example, for a FS frequency of 10kHz at a FS input of 1mA, C = 9500pF. Calibration is effected by applying the full-scale input and adjusting R2 for the correct reading.

This alternative adjustment scheme may also be used when it is desired to present an exact input resistance in the negative-voltage mode. The scaling relationship is then

$$f = \frac{V}{R_{exact}} \cdot \frac{1}{10.5\ C}$$

The calibration procedure is then similar to that used for positive input voltages, except that the scale adjustment is by means of R2.

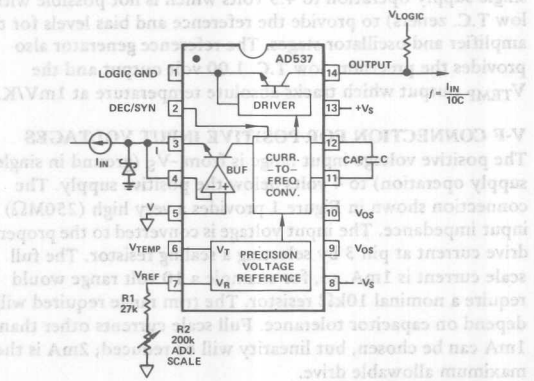

Figure 3. Scale Adjustment for Current Inputs

INPUT PROTECTION

The AD537 was designed to be used with a minimum of additional hardware. However, the successful application of a precision IC involves a good understanding of possible pitfalls and the use of suitable precautions.

The $-V_{IN}$, $+V_{IN}$ and I_{IN} pins should not be driven more than 300mV below $-V_S$. This would cause internal junctions to conduct, possibly damaging the IC. The AD537 can be protected from "below $-V_S$" inputs by a Schottky diode, CR1 (HP5082-2811) as shown in Figure 3. It is also desirable not to drive $+V_{IN}$, $-V_{IN}$ and I_{IN} above $+V_S$. In operation, the converter will become very nonlinear for inputs above ($+V_S$ -3.5V). Control currents above 2mA will also cause nonlinearity.

The 80dB dynamic range of the AD537 guarantees operation from a control current of 1mA (nominal FS) down to 100nA (equivalent to 1mV to 10V FS). Below 100nA improper operation of the oscillator may result, causing a false indication of input amplitude. In many cases this might be due to short-lived noise spikes which become added to the input. For example, when scaled to accept a FS input of 1V, the -80dB level is only 100μV, so when the mean input is only 60dB below FS (1mV), noise spikes of 0.9mV are sufficient to cause momentary malfunction.

This effect can be minimized by using a simple low-pass filter ahead of the converter and a guard ring around the I_{IN} or $-V_{IN}$ pins. For a FS of 10kHz a single-pole filter with a time-constant of 100ms (Figure 2) will be suitable, but the optimum configuration will depend on the application and type of signal processing. Noise spikes are only likely to be a cause of error when the input current remains near its minimum value for long periods of time; above 100nA (1mV) full integration of additive input noise occurs.

The AD537 is somewhat susceptible to interference from other signals. The most sensitive nodes (besides the inputs) are the capacitor terminals and the SYNC pin. The timing capacitor should be located as close as possible to the AD537 to minimize signal pickup in the leads. In some cases, guard rings or shielding may be required. The SYNC pin should be decoupled through a 0.005μF (or larger) capacitor to pin 13 ($+V_S$). This minimizes the possibility that the AD537 will attempt to synchronize to a spurious signal. This precaution is unnecessary on the metal can package since the SYNC function is not brought out to a package pin and is thus not susceptible to pickup.

DECOUPLING

It is good engineering practice to use bypass capacitors on the supply-voltage pins and to insert small-valued resistors (10 to 100Ω) in the supply lines to provide a measure of decoupling between the various circuits in a system. Ceramic capacitors of 0.1μF to 1.0μF should be applied between the supply-voltage pins and analog signal ground for proper bypassing on the AD537.

A decoupling capacitor may also be useful from $+V_S$ to SYNC in those applications where very low cycle-to-cycle period variation (jitter) is demanded. By placing a capacitor across $+V_S$ and SYNC this noise is reduced. On the 10kHz FS range, a 6.8μF capacitor reduces the jitter to one in 20,000 which is adequate for most applications. A tantalum capacitor should be used to avoid errors due to dc leakage.

NONLINEARITY SPECIFICATION

The preferred method for specifying linearity error is in terms of the maximum deviation from the ideal relationship after calibrating the converter at full scale and "zero". This error will vary with the full scale frequency and the mode of operation. The AD537 operates best at a 10kHz full scale frequency with a negative voltage input; the linearity is typically within ±0.05%. Operating at higher frequencies or with positive inputs will degrade the linearity as indicates in the Specifications table. The shape of a typical linearity plot is given in Figure 4.

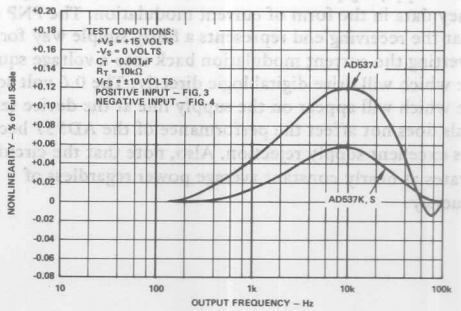

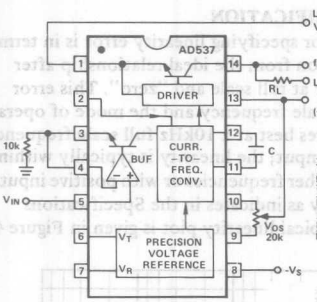

Figure 4b. Typical Nonlinearity Error with 100kHz F.S. Output

OUTPUT INTERFACING CONSIDERATIONS

The design of the output stage allows easy interfacing to all digital logic families. The collector and emitter of the output NPN transistor are both uncommitted; the emitter can be tied to any voltage between $-V_S$ and 4 volts below $+V_S$. The open collector can be pulled up to a voltage 36 volts above the emitter regardless of $+V_S$. The high power output stage can supply up to 20mA (10mA for "H" package) at a maximum saturation voltage of 0.4 volts. The stage limits the output current at 25mA; it can handle this limit indefinitely without damaging the device.

Figure 5 shows the AD537 with a standard 0 to +10 volt input connection and the output stage connections. The values for the logic common voltage, pull-up resistor, positive logic level, and $-V_S$ supply are given in the accompanying chart for several logic forms.

	V_{CC}	V_{EE}	R_L	$-V_S$
TTL/DTL	+5	GND	5k	GND
5V CMOS	+5	GND	20k	GND
15V CMOS/HNIL	+15	GND	10k	GND
ECL 10k	0	-8	5k	-8 to -15
ECL 2.5k	+1.3	-2	5k	-5
PMOS	0	-15	10k	-15

Figure 5. Interfacing Standard Logic Families

APPLICATIONS

The diagrams and descriptions of the following applications are provided to stimulate the discerning engineer with alternative circuit design ideas. "Applications of the AD537 IC Voltage-to-Frequency Converter", available from Analog Devices on request, covers a wider range of topics and concepts in data conversion and data transmission using voltage-to-frequency converters.

TRUE TWO-WIRE DATA TRANSMISSION

Figure 6 shows the AD537 in a true two-wire data transmission scheme. The twisted-pair transmission lines serves the dual purpose of supplying power to the device and also carrying frequency data in the form of current modulation. The PNP circuit at the receiving end represents a fairly simple way for converting the current modulation back into a voltage square wave which will drive digital logic directly. The 0.6 volt square wave which will appear on the supply line at the device terminals does not affect the performance of the AD537 because of its excellent supply rejection. Also, note that the circuit operates at nearly constant average power regardless of frequency.

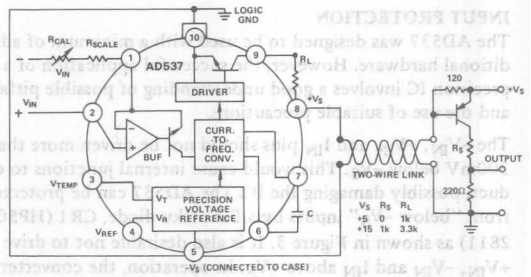

Figure 6. True Two-Wire Operation

F-V CONVERTERS

The AD537 can be used as a high linearity VCO in a phase-locked loop to accomplish frequency-to-voltage conversion. By operating the loop without a low-pass filter in the feedback path (first-order system), it can lock to any frequency from zero to an upper limit determined by the design, responding in three or four cycles to a step change of input frequency. In practice, the overall response time is determined by the characteristics of the averaging filter which follows the PLL.

Figure 7 shows a connection using a low-power TTL quad open-collector nand gate which serves as the phase comparator. The input signal should be a pulse train or square wave with characteristics similar to TTL or 5-volt CMOS outputs. Any duty cycle is acceptable, but the minimum pulse width is 40μs. The output voltage is one volt for a 10kHz input frequency. The output as shown here is at a fairly high impedance level; for many situations an additional buffer may be required.

Trimming is similar to V-F application trimming. First set the V_{OS} trimmer to mid-scale. Apply a 10kHz input frequency and trim the 2kΩ potentiometer for 1.00 volts out. Then apply a 10Hz waveform and trim the V_{OS} for 1mV out. Finally, retrim the full scale output at 10kHz. Other frequency scales can be obtained by appropriate scaling of timing components.

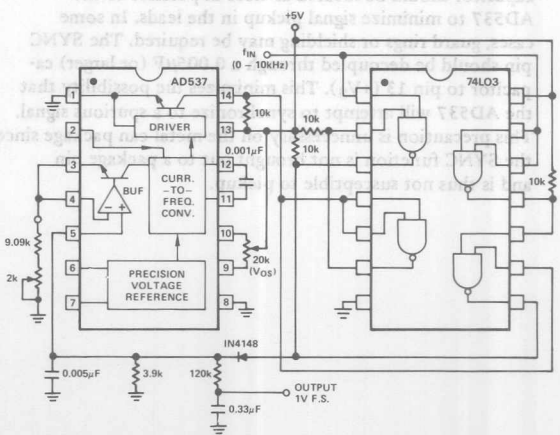

Figure 7. 10kHz F-V Converter

TEMPERATURE-TO-FREQUENCY CONVERSION

The linear temperature-proportional output of the AD537 can be used as shown in these applications to perform various direct temperature-to-frequency conversion functions; it can also be used with other external connections in a temperature sensing or compensation scheme. If the sensor output is used externally, it should be buffered through an op amp since loading that point will cause significant error in the sensor output as well as in the main V-F converter circuitry.

An absolute temperature (Kelvin)-to-frequency converter is very easily accomplished, as shown in Figure 8. The 1mV per K output serves as the input to the buffer amplifier, which then scales the oscillator drive current to a nominal 298μA at +25°C (298K). Use of a 1000pF capacitor results in a corresponding frequency of 2.98kHz. Setting the single 2kΩ trimmer for the correct frequency at a well-defined temperature near +25°C will normally result in an accuracy of ±2°C from -55°C to +125°C (using an AD537S). An NPO ceramic capacitor is recommended to minimize nonlinearity due to capacitance drift.

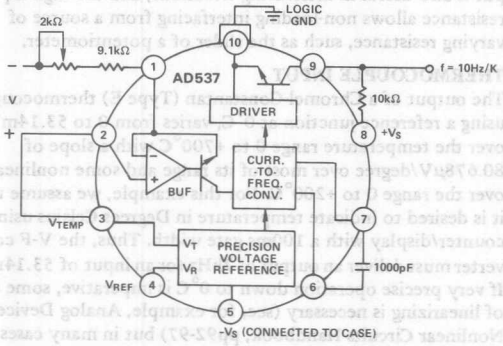

Figure 8. Absolute Temperature to Frequency Converter

OFFSET TEMPERATURE SCALES

Many other temperature scales can be set up by offsetting the temperature output with the voltage reference output. Such a scheme is shown by the Celsius-to-frequency converter in Figure 9. Corresponding component values for a Fahrenheit-to-frequency converter which give 10Hz/°F are given in parentheses.

A simple calibration procedure which will provide ±2°C accuracy requires substitution of a 7.27k resistor for the series combination of the 6.04k with the 2k trimmer; then simply set the 500Ω trimmer to give 250Hz at +25°C.

High accuracy calibration procedure:

1. Measure room temperature in K.
2. Measure temperature output at pin 6 at that temperature.
3. Calculate offset adjustment as follows:

$$\text{Offset Voltage (mV)} = \frac{V_{TEMP}\ (\text{pin 6})\ (\text{mV})}{\text{Room temp (K)}} \times 273.2$$

4. Temporarily disconnect 49Ω resistor (or 500Ω pot) and trim 2kΩ pot to give the offset voltage at the indicated node. Reconnect 49Ω resistor.
5. Adjust slope trimmer to give proper frequency at room temperature (+25°C = 250Hz).
   Adjustment for °F or any other scale is analogous.

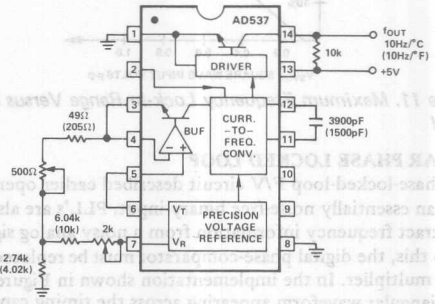

Figure 9. Offset Temperature Scale Converters-Centigrade and (Fahrenheit) to Frequency

SYNCHRONOUS OPERATION

The SYNC terminal at pin 2 of the DIP package can be used to synchronize a free running AD537 to a master oscillator, either at a multiple or a sub-multiple of the primary frequency. The preferred connection is shown in Figure 10. The diodes are used to produce the proper drive magnitude from high level signals. The SYNC terminal can also be used to shut off the oscillator. Shorting the terminal to $+V_S$ will stop the oscillator, and the output will go high (output NPN off).

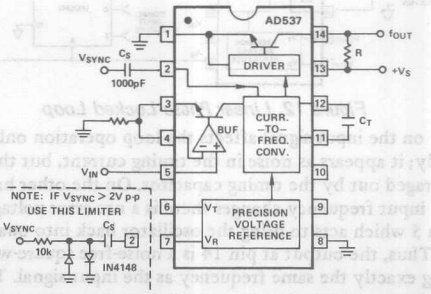

Figure 10. Connection for Synchronous Operation

Figure 11 shows the maximum pull-in range available at a given signal level; the optimum signal is a 0.8 to 1.0 volt square wave; signals below 0.1 volt will have no effect; signals above 2 volts p-p will disable the oscillator. The AD537 can normally be synchronized to a signal which forces it to a higher frequency up to 30% above the nominal free-running frequency, it can only be brought down about 1-2%.

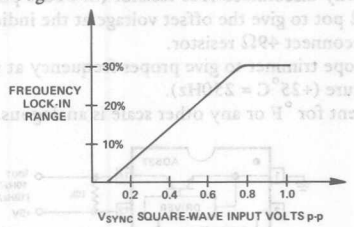

Figure 11. Maximum Frequency Lock-In Range Versus Sync. Signal

LINEAR PHASE LOCKED LOOP

The phase-locked-loop F/V circuit described earlier operates from an essentially noise-free binary input. PLL's are also used to extract frequency information from a noisy analog signal. To do this, the digital phase-comparator must be replaced by a linear multiplier. In the implementation shown in Figure 12, the triangular waveform appearing across the timing capacitor is used as one of the multiplier inputs; the signal provides the other input. It can be shown that the mean value of the multiplier output is zero when the two signals are in quadrature. In this condition, the ripple in the error signal is also quite small. Thus, the voltage at pin 5 is essentially zero, and the frequency is determined primarily by the current in the timing resistor, controlled either manually or by a control voltage.

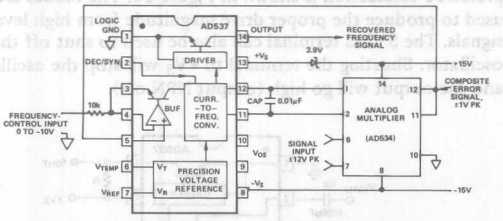

Figure 12. Linear Phase-Locked Loop

Noise on the input signal affects the loop operation only slightly; it appears as noise in the timing current, but this is averaged out by the timing capacitor. On the other hand, if the input frequency changes there is a net error voltage at pin 5 which acts to bring the oscillator back into quadrature. Thus, the output at pin 14 is a noise-free square-wave having exactly the same frequency as the input signal. The effectiveness of this circuit can be judged from Figure 13 which shows the response to an input of 1V rms 1kHz sinusoid plus 1V rms Gaussian noise. The positive supply to the AD537 is reduced by about 4V in order to keep the voltages at pins 11 and 12 within the common-mode range of the AD534.

Since this is also a first-order loop the circuit possesses a very wide capture range. However, even better noise-integrating properties can be achieved by adding a filter between the multiplier output and the VCO input. Details of suitable filter characteristics can be found in the standard texts on the subject.

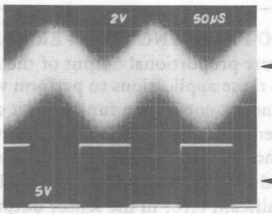

Figure 13. Performance of AD537 Linear Phase-Locked Loop

By connecting the multiplier output to the lower end of the timing resistor and moving the control input to pin 5, a high-resistance frequency-control input is made available. However, due to the reduced supply voltage, this input cannot exceed +6V.

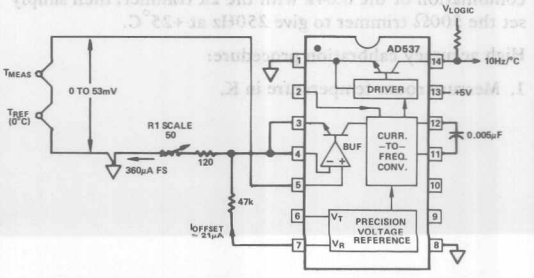
TRANSDUCER INTERFACE

The AD537 was specifically designed to accept a broad range of input signals, particularly small voltage signals, which may be converted directly (unlike many V-F converters which require signal pre-conditioning). The 1.00V stable reference output is also useful in interfacing situations, and the high input resistance allows non-loading interfacing from a source of varying resistance, such as the slider of a potentiometer.

THERMOCOUPLE INPUT

The output of a Chromel-Constantan (Type E) thermocouple, using a reference junction at 0°C, varies from 0 to 53.14mV over the temperature range 0 to +700°C with a slope of 80.678μV/degree over most of its range and some nonlinearity over the range 0 to +200°C. For this example, we assume that it is desired to indicate temperature in Degrees Celsius using a counter/display with a 100ms gate width. Thus, the V-F converter must deliver an output of 7kHz for an input of 53.14mV. If very precise operation down to 0°C is imperative, some sort of linearizing is necessary (see, for example, Analog Devices' Nonlinear Circuits Handbook, pp92-97) but in many cases operation is only needed over part of the range.

The circuit shown in Figure 14 provides good accuracy from +300°C to +700°C. The extrapolation of the temperature-voltage curve back to 0°C shows that an offset of -3.34mV is required to fit the curve most exactly. This small amount of voltage can be introduced without an additional calibration step using the +1.00V output of the AD537. To adjust the scale, the thermocouple should be raised to a known reference temperature near 500°C and the frequency adjusted to value using R1. The error should be within ±0.2% over the range 400°C to 700°C.



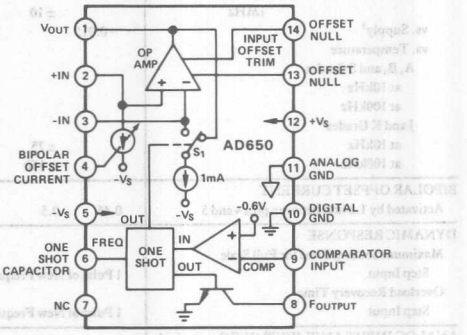


Figure 14. Thermocouple Interface with First-Order Linearization

AD650

FEATURES

- V/F Conversion to 1MHz
- Reliable Monolithic Construction
- Very Low Nonlinearity
  - 0.002% typ at 10kHz
  - 0.005% typ at 100kHz
  - 0.07% typ at 1MHz
- Input Offset Trimmable to Zero
- CMOS or TTL Compatible
- Unipolar, Bipolar, or Differential V/F
- V/F or F/V Conversion
- Available in Surface Mount
- MIL-STD-883-Compliant Versions Available

PIN CONFIGURATION

PRODUCT DESCRIPTION

The AD650 V/F/V (voltage-to-frequency or frequency-to-voltage converter) provides a combination of high frequency operation and low nonlinearity previously unavailable in monolithic form. The inherent monotonicity of the V/F transfer function makes the AD650 useful as a high-resolution analog-to-digital converter. A flexible input configuration allows a wide variety of input voltage and current formats to be used, and an open-collector output with separate digital ground allows simple interfacing to either standard logic families or opto-couplers.

The linearity error of the AD650 is typically 20ppm (0.002% of full scale) and 50ppm (0.005%) maximum at 10kHz full scale. This corresponds to approximately 14-bit linearity in an analog-to-digital converter circuit. Higher full-scale frequencies or longer count intervals can be used for higher resolution conversions. The AD650 has a useful dynamic range of six decades allowing extremely high resolution measurements. Even at 1MHz full scale, linearity is guaranteed less than 1000ppm (0.1%) on the AD650KN, KP, BD and SD grades.

In addition to analog-to-digital conversion, the AD650 can be used in isolated analog signal transmission applications, phased-locked-loop circuits, and precision stepper motor speed controllers. In the F/V mode, the AD650 can be used in precision tachometer and FM demodulator circuits.

The input signal range and full-scale output frequency are user-programmable with two external capacitors and one resistor. Input offset voltage can be trimmed to zero with an external potentiometer.

The AD650JN and AD650KN are offered in a plastic 14-pin DIP package. The AD650JP and AD650KP are available in a 20-pin plastic leaded chip carrier (PLCC). Both plastic packaged versions of the AD650 are specified for the commerical (0 to +70°C) temperature range. For industrial temperature range (−25°C to +85°C) applications, the AD650AD and AD650BD are offered in a ceramic package. The AD650SD is specified for the full −55°C to +125°C extended temperature range.

PRODUCT HIGHLIGHTS

1. In addition to very high linearity, the AD650 can operate at full scale output frequency up to 1MHz. The combination of these two features makes the AD650 an inexpensive solution for applications requiring high resolution monotonic A/D conversion.
2. The AD650 has a very versatile architecture that can be configured to accommodate bipolar, unipolar, or differential input voltages, or unipolar input currents.
3. TTL or CMOS compatibility is achieved using an open collector frequency output. The pullup resistor can be connected to voltages up to +30V, or +15V or +5V for conventional CMOS or TTL logic levels.
4. The same components used for V/F conversion can also be used for F/V conversion by adding a simple logic biasing network and reconfiguring the AD650.
5. The AD650 provides separate analog and digital grounds. This feature allows prevention of ground loops in real-world applications.
6. The AD650 is available in versions compliant with MIL-STD-883. Refer to the Analog Devices Military Products Databook or current AD650/883B data sheet for detailed specifications.

3

CIRCUIT OPERATION

UNIPOLAR CONFIGURATION

The AD650 is a *charge balance* voltage-to-frequency converter. In the connection diagram shown in Figure 1, or the block diagram of Figure 2a, the input signal is converted into an equivalent current by the input resistance R_{IN}. This current is *exactly* balanced by an internal feedback current delivered in short, timed bursts from the switched 1mA internal current source. These bursts of current may be thought of as precisely defined packets of charge. The required number of charge packets, each producing one pulse of the output transistor, depends upon the amplitude of the input signal. Since the number of charge packets delivered per unit time is dependent on the input signal amplitude, a linear voltage-to-frequency transformation will be accomplished. The frequency output is furnished via an open collector transistor.

A more rigorous analysis demonstrates how the charge balance voltage-to-frequency conversion takes place.

A block diagram of the device arranged as a V to F converter is shown in Figure 2a. The unit is comprised of an input integrator, a current source and steering switch, a comparator and a one-shot. When the output of the one-shot is low, the current steering switch S_1 diverts all the current to the output of the op amp; this is called the Integration Period. When the one-shot has been triggered and its output is high, the switch S_1 diverts all the current to the summing junction of the op amp; this is called the Reset Period. The two different states are shown in Figure 2 along with the various branch currents. It should be noted that the output current from the op amp is the same for either state, thus minimizing transients.

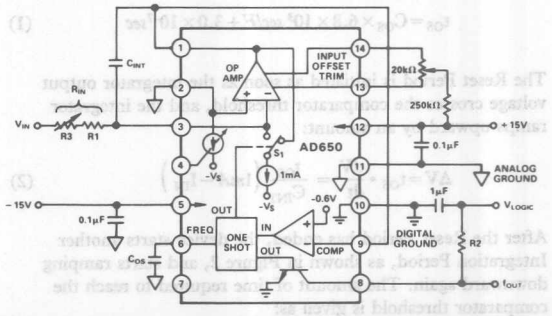

Figure 1. Connection Diagram for V/F Conversion, Positive Input Voltage

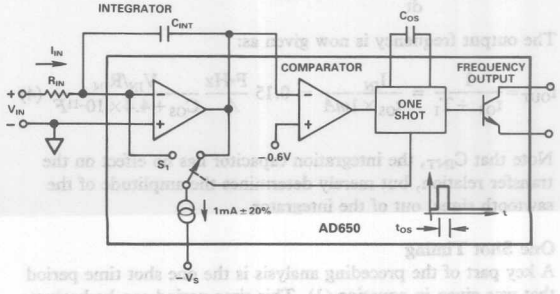

Figure 2a. Block Diagram

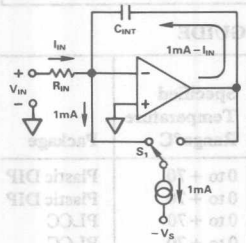

Figure 2b. Reset Mode

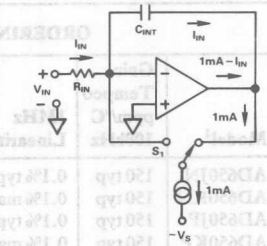

Figure 2c. Integrate Mode

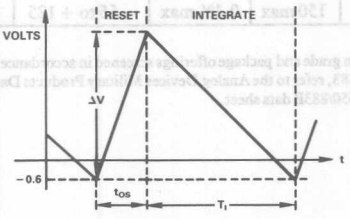

Figure 2d. Voltage Across C_{INT}

The positive input voltage develops a current ($I_{IN} = V_{IN}/R_{IN}$) which charges the integrator capacitor C_{INT}. As charge builds up on C_{INT}, the output voltage of the integrator ramps downward towards ground. When the integrator output voltage (pin 1) crosses the comparator threshold (−0.6 volt) the comparator triggers the one shot, whose time period, t_{OS} is determined by the one shot capacitor C_{OS}.

Specifically, the one shot time period is:

$$t_{OS} = C_{OS} \times 6.8 \times 10^3\ sec/F + 3.0 \times 10^{-7} sec \quad (1)$$

The Reset Period is initiated as soon as the integrator output voltage crosses the comparator threshold, and the integrator ramps upward by an amount:

$$\Delta V = t_{OS} \cdot \frac{dV}{dt} = \frac{t_{OS}}{C_{INT}} \left(1mA - I_{IN}\right) \quad (2)$$

After the Reset Period has ended, the device starts another Integration Period, as shown in Figure 2, and starts ramping downward again. The amount of time required to reach the comparator threshold is given as:

$$T_I = \frac{\Delta V}{\frac{dV}{dt}} = \frac{t_{OS}/C_{INT}(1mA - I_{IN})}{I_{IN}/C_{INT}} = t_{OS}\left(\frac{1mA}{I_{IN}} - 1\right) \quad (3)$$

The output frequency is now given as:

$$f_{OUT} = \frac{1}{t_{OS} + T_I} = \frac{I_{IN}}{t_{OS} \times 1mA} = 0.15\ \frac{F \cdot Hz}{A}\ \frac{V_{IN}/R_{IN}}{C_{OS} + 4.4 \times 10^{-11} F} \quad (4)$$

Note that C_{INT}, the integration capacitor has no effect on the transfer relation, but merely determines the amplitude of the sawtooth signal out of the integrator.

One Shot Timing

A key part of the preceding analysis is the one shot time period that was given in equation (1). This time period can be broken down into approximately 300ns of propagation delay, and a second time segment dependent linearly on timing capacitor C_{OS}. When the one shot is triggered, a voltage switch that holds pin 6 at analog ground is opened allowing that voltage to change. An internal 0.5mA current source connected to pin 6 then draws its current out of C_{OS}, causing the voltage at pin 6 to decrease linearly. At approximately −3.4V, the one shot resets itself, thereby ending the timed period and starting the V/F conversion cycle over again. The total one shot time period can be written mathematically as:

$$t_{OS} = \frac{\Delta V\ C_{OS}}{I_{DISCHARGE}} + T_{GATE\ DELAY} \quad (5)$$

substituting actual values quoted above,

$$t_{OS} = \frac{-3.4V \times C_{OS}}{-0.5 \times 10^{-3} A} + 300 \times 10^{-9} sec \quad (6)$$

This simplifies into the timed period equation given above.

COMPONENT SELECTION

Only four component values must be selected by the user. These are input resistance R_{IN}, timing capacitor C_{OS}, logic resistor R_2, and integration capacitor C_{INT}. The first two determine the input voltage and full scale frequency, while the last two are determined by other circuit considerations.

Of the four components to be selected, R_2 is the easiest to define. As a pull up resistor, it should be chosen to limit the current through the output transistor to 8mA if a TTL maximum V_{OL} of 0.4V is desired. For example, if a 5V logic supply is used, R_2 should be no smaller than 5V/8mA or 625Ω. A larger value can be used if desired.

R_{IN} and C_{OS} are the only two parameters available to set the full scale frequency to accommodate the given signal range. The "swing" variable that is affected by the choice of R_{IN} and C_{OS} is nonlinearity. The selection guide of Figure 3 shows this quite graphically. In general, larger values of C_{OS} and lower full scale input currents (higher values of R_{IN}) provide better linearity. In Figure 3, the implications of four different choices of R_{IN} are shown. Although the selection guide is set up for a unipolar configuration with a zero to 10V input signal range, the results can be extended to other configurations and input signal ranges. For a full scale frequency of 100kHz (corresponding to 10V input), you can see that among the available choices, R_{IN} = 20k and C_{OS} = 620pF gives the lowest nonlinearity, 0.0038%. Also, if you wish to use the highest frequency that will give the 20ppm minimum nonlinearity, it is approximately 33kHz (40.2kΩ and 1000pF).

For input signal spans other than 10V, the input resistance must be scaled proportionately. For example, if 100kΩ is called out for a 0–10V span, 10k would be used with a 0–1V span, or 200kΩ with a ±10V bipolar connection.

The last component to be selected is the integration capacitor C_{INT}. In almost all cases, the best value for C_{INT} can be calculated using the equation:

$$C_{INT} = \frac{10^{-4} F/sec}{f_{MAX}} \quad (1000pF\ minimum) \quad (7)$$

When the proper value for C_{INT} is used, the charge balance architecture of the AD650 provides continuous integration of the input signal, hence large amounts of noise and interference

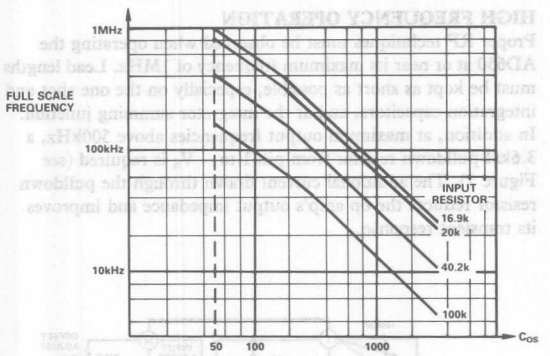

Figure 3a. Full Scale Frequency vs. C_{OS}

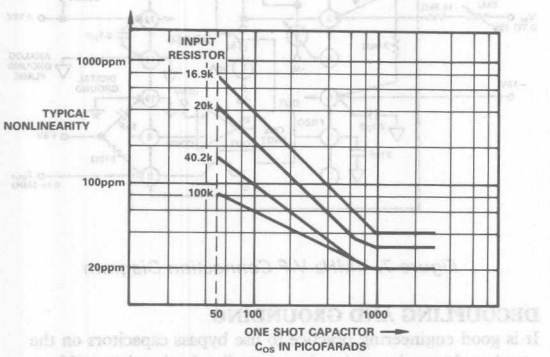

Figure 3b. Typical Nonlinearity vs. C_{OS}

can be rejected. If the output frequency is measured by counting pulses during a constant gate period, the integration provides infinite normal mode rejection for frequencies corresponding to the gate period and its harmonics. However, if the integrator stage becomes saturated by an excessively large noise pulse, the continuous integration of the signal will be interrupted, allowing the noise to appear at the output. If the approximate amount of noise that will appear on C_{INT} is known (V_{NOISE}), the value of C_{INT} can be checked using the following inequality:

$$C_{INT} > \frac{t_{OS} \times 1 \times 10^{-3} A}{+V_S - 3V - V_{NOISE}} \quad (8)$$

For example, consider an application calling for a maximum frequency of 75kHz, a 0–1 volt signal range, and supply voltages of only ±9 volts. The component selection guide of Figure 3 is used to select 2.0kΩ for R_{IN} and 1000pF for C_{OS}. This results in a one shot time period of approximately 7μs. Substituting 75kHz into equation 7 yields a value of 1300pF for C_{INT}. When the input signal is near zero, 1mA flows through the integration capacitor to the switched current sink during the reset phase, causing the voltage across C_{INT} to increase by approximately 5.5 volts. Since the integrator output stage requires approximately 3 volts head room for proper operation, only 0.5 volt margin remains for integrating extraneous noise on the signal line. A negative noise pulse at this time might saturate the integrator, causing an error in signal integration. Increasing C_{INT} to 1500 or 2000pF will provide much more noise margin, thereby eliminating this potential trouble spot.

BIPOLAR V/F

Figure 4 shows how the internal bipolar current sink is used to provide a half-scale offset for a ±5V signal range, while providing a 100kHz maximum output frequency. The nominally 0.5mA (±10%) offset current sink is enabled when a 1.24kΩ resistor is connected between pins 4 and 5. Thus, with the grounded 10kΩ nominal resistance shown, a −5V offset is developed at pin 2. Since pin 3 must also be at −5V, the current through R_{IN} is 10V/40kΩ = +0.25mA at V_{IN} = +5V, and 0mA at V_{IN} = −5V.

Components are selected using the same guidelines outlined for the unipolar configuration with one alteration. The voltage across the total signal range must be equated to the maximum

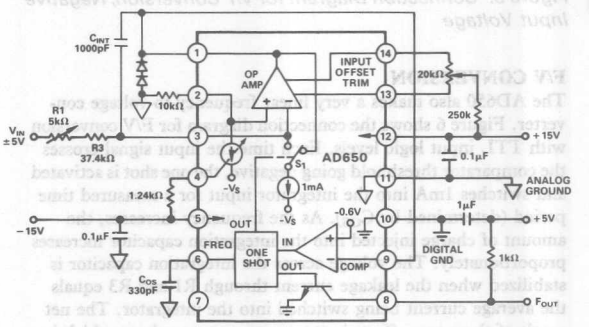

Figure 4. Connections for ±5V Bipolar V/F with 0 to 100kHz TTL Output

input voltage in the unipolar configuration. In other words, the value of the input resistor R_{IN} is determined by the input voltage span, not the maximum input voltage. A diode from pin 1 to ground is also recommended. This is discussed further under "Other Circuit Conditions".

As in the unipolar circuit, R_{IN} and C_{OS} must have low temperature coefficients to minimize the overall gain drift. The 1.24kΩ resistor used to activate the 0.5mA offset current should also have a low temperature coefficient. The bipolar offset current has a temperature coefficient of approximately −200ppm/°C.

UNIPOLAR V/F, NEGATIVE INPUT VOLTAGE

Figure 5 shows the connection diagram for V/F conversion of negative input voltages. In this configuration full scale output frequency occurs at negative full scale input, and zero output frequency corresponds with zero input voltage.

A very high impedance signal source may be used since it only drives the noninverting integrator input. Typical input impedance at this terminal is 1GΩ or higher. For V/F conversion of positive input signals using the connection diagram of Figure 1, the signal generator must be able to source the integration current to drive the AD650. For the negative V/F conversion circuit of Figure 5, the integration current is drawn from ground through R1 and R3, and the active input is high impedance.

Circuit operation for negative input voltages is very similar to positive input unipolar conversion described in a previous section. For best operating results use component equations listed in that section.

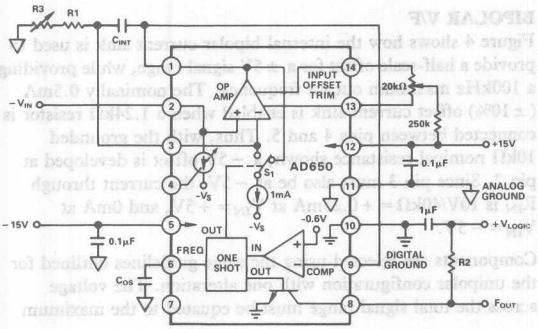

Figure 5. Connection Diagram for V/F Conversion, Negative Input Voltage

F/V CONVERSION

The AD650 also makes a very linear frequency-to-voltage converter. Figure 6 shows the connection diagram for F/V conversion with TTL input logic levels. Each time the input signal crosses the comparator threshhold going negative, the one shot is activated and switches 1mA into the integrator input for a measured time period (determined by C_{OS}). As the frequency increases, the amount of charge injected into the integration capacitor increases proportionately. The voltage across the integration capacitor is stabilized when the leakage current through R1 and R3 equals the average current being switched into the integrator. The net result of these two effects is an average output voltage which is proportional to the input frequency. Optimum performance can be obtained by selecting components using the same guidelines and equations listed in the V/F conversion section.

The circuit of Figure 6 can be biased to accommodate almost any input signal waveform. With a TTL input, the 1000pF coupling capacitor and 2.2kΩ resistor creates a clean negative spike that triggers the one shot on negative going edges. For input signals with slower edges, a larger capacitor and/or resistor may be used as long as the comparator is never exposed to a voltage lower than −0.6V for longer than the one shot time period. If this happens, the one shot will trigger itself more than once per cycle, creating discontinuities in the F/V transfer function. An input pulse greater than 100ns but less than $0.3 \times t_{OS}$ is recommended (t_{OS} is defined by equation 1 in the circuit operation section, unipolar configuration).

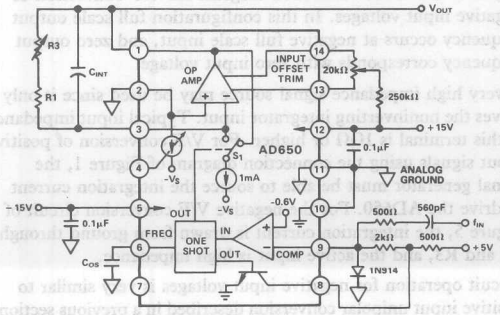

Figure 6. Connection Diagram for F/V Conversion

HIGH FREQUENCY OPERATION

Proper RF techniques must be observed when operating the AD650 at or near its maximum frequency of 1MHz. Lead lengths must be kept as short as possible, especially on the one shot and integration capacitors, and at the integrator summing junction. In addition, at maximum output frequencies above 500kHz, a 3.6kΩ pulldown resistor from pin 1 to $-V_S$ is required (see Figure 7). The additional current drawn through the pulldown resistor reduces the op amp's output impedance and improves its transient response.

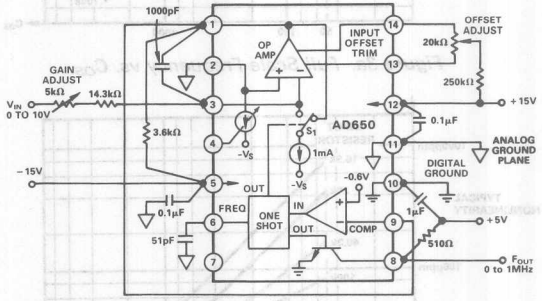

Figure 7. 1MHz V/F Connection Diagram

DECOUPLING AND GROUNDING

It is good engineering practice to use bypass capacitors on the supply-voltage pins and to insert small-valued resistors (10 to 100Ω) in the supply lines to provide a measure of decoupling between the various circuits in a system. Ceramic capacitors of 0.1μF to 1.0μF should be applied between the supply-voltage pins and analog signal ground for proper bypassing on the AD650.

In addition, a larger board level decoupling capacitor of 1μF to 10μF should be located relatively close to the AD650 on each power supply line. Such precautions are imperative in high resolution data acquisition applications where one expects to exploit the full linearity and dynamic range of the AD650. Although some types of circuits may operate satisfactorily with power supply decoupling at only one location on each circuit board, such practice is strongly discouraged in high accuracy analog design.

Separate digital and analog grounds are provided on the AD650. The emitter of the open collector frequency output transistor is the only node returned to the digital ground. All other signals are referred to analog ground. The purpose of the two separate grounds is to allow isolation between the high precision analog signals and the digital section of the circuitry. As much as several hundred millivolts of noise can be tolerated on the digital ground without affecting the accuracy of the VFC. Such ground noise is inevitable when switching the large currents associated with the frequency output signal.

At 1MHz full scale, it is necessary to use a pull-up resistor of about 500Ω in order to get the rise time fast enough to provide well defined output pulses. This means that from a 5 volt logic supply, for example, the open collector output will draw 10mA.

This much current being switched will surely cause ringing on long ground runs due to the self inductance of the wires. For instance, #20 gauge wire has an inductance of about 20nH per inch; a current of 10mA being switched in 50ns at the end of 12 inches of 20 gauge wire will produce a voltage spike of 50mV. The separate digital ground of the AD650 will easily handle these types of switching transients.

A problem will remain from interference caused by radiation of electro-magnetic energy from these fast transients. Typically, a voltage spike is produced by inductive switching transients; these spikes can capacitively couple into other sections of the circuit. Another problem is ringing of ground lines and power supply lines due to the distributed capacitance and inductance of the wires. Such ringing can also couple interference into sensitive analog circuits. The best solution to these problems is proper bypassing of the logic supply at the AD650 package. A 1μF to 10μF tantalum capacitor should be connected directly to the supply side of the pull-up resistor and to the digital ground – pin 10. The pull-up resistor should be connected directly to the frequency output – pin 8. The lead lengths on the bypass capacitor and the pull up resistor should be as short as possible. The capacitor will supply (or absorb) the current transients, and large ac signals will flow in a physically small loop through the capacitor, pull up resistor, and frequency output transistor. It is important that the loop be physically small for two reasons: first, there is less self-inductance if the wires are short, and second, the loop will not radiate RFI efficiently.

The digital ground (pin 10) should be separately connected to the power supply ground. Note that the leads to the digital power supply are only carrying dc current and cannot radiate RFI. There may also be a dc ground drop due to the difference in currents returned on the analog and digital grounds. This will not cause any problem. In fact, the AD650 will tolerate as much as 0.25 volt dc potential difference between the analog and digital grounds. These features greatly ease power distribution and ground management in large systems. Proper technique for grounding requires separate digital and analog ground returns to the power supply. Also, the signal ground must be referred directly to analog ground (pin 11) at the package. All of the signal grounds should be tied directly to pin 11, especially the one-shot capacitor. More information on proper grounding and reduction of interference can be found in reference 1.

TEMPERATURE COEFFICIENTS

The drift specifications of the AD650 do not include temperature effects of any of the supporting resistors or capacitors. The drift of the input resistors R1 and R3 and the timing capacitor C_{OS} directly affect the overall temperature stability. In the application of Figure 2, a 10ppm/°C input resistor used with a 100ppm/°C capacitor may result in a maximum overall circuit gain drift of:

150ppm/°C (AD650A) + 100ppm/°C (C_{OS}) + 10ppm/°C (R_{IN}) = 260ppm/°C

In bipolar configuration, the drift of the 1.24kΩ resistor used to activate the internal bipolar offset current source will directly affect the value of this current. This resistor should be matched to the resistor connected to the op amp noninverting input (pin 2), see Figure 4. That is, the temperature coefficients of these two resistors should be equal. If this is the case, then the effects of the temperature coefficients of the resistors cancel each other, and the drift of the offset voltage developed at the op amp noninverting input will be determined solely by the AD650. Under these conditions the TC of the bipolar offset voltage is typically −200ppm/°C and is a maximum of −300ppm/°C. The offset voltage always decreases in magnitude as temperature is increased.

Other circuit components do not directly influence the accuracy of the VFC over temperature changes as long as their actual values are not so different from the nominal value as to preclude operation. This includes the integration capacitor, C_{INT}. A change in the capacitance value of C_{INT} simply results in a different rate of voltage change across the capacitor. During the Integration Phase (refer to Figure 2), the rate of voltage change across C_{INT} has the opposite effect that it does during the Reset Phase. The result is that the conversion accuracy is unchanged by either drift or tolerance of C_{INT}. The net effect of a change in the integrator capacitor is simply to change the peak to peak amplitude of the sawtooth waveform at the output of the integrator.

The gain temperature coefficient of the AD650 is not a constant value. Rather the gain TC is a function of both the full scale frequency and the ambient temperature. At a low full scale frequency, the gain TC is determined primarily by the stability of the internal reference–a buried zener reference. This low speed gain TC can be quite good; at 10kHz full scale, the gain TC near 25°C is typically 0 ±50ppm/°C. Although the gain TC changes with ambient temperature (tending to be more positive at higher temperatures), the drift remains within a ±75ppm/°C window over the entire military temperature range. At full scale frequencies higher than 10kHz dynamic errors become much more important than the static drift of the dc reference. At a full scale frequency of 100kHz and above, these timing errors dominate the gain TC. For example, at 100kHz full scale frequency (R_{IN} = 40k and C_{OS} = 330pF) the gain TC near room temperature is typically −80 ±50ppm/°C, but at an ambient temperature near +125°C, the gain TC tends to be more positive and is typically +15 ±50ppm/°C. This information is presented in a graphical form in Figure 8. The gain TC always tends to become more positive at higher temperatures. Therefore it is possible to adjust the gain TC of the AD650 by using a one-shot capacitor with an appropriate TC to cancel the drift of the circuit. For example, consider the 100kHz full scale frequency. An average drift of −100ppm/°C means that as temperature is increased, the circuit will produce a lower frequency in reponse to a given input voltage. This means that the one-shot capacitor must decrease in value as temperature increases in order to compensate the gain TC of the AD650; that is, the capacitor must have a TC of −100ppm/°C. Now consider the 1MHz full scale frequency.

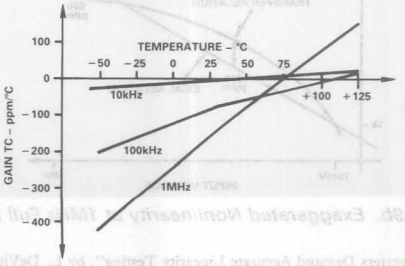

Figure 8. Gain TC vs. Temperature

[1]"Noise Reduction Techniques in Electronic Systems", by H. W. OTT, (John Wiley, 1976).

It is not possible to achieve very much improvement in performance unless the expected ambient temperature range is known. For example, in a constant low temperature application such as gathering data in an Arctic climate (approximately −20°C), a C_{OS} with a drift of −310ppm/°C is called for in order to compensate the gain drift of the AD650. However, if that circuit should see an ambient temperature of +75°C, the C_{OS} cap would change the gain TC from approximately 0ppm to +310ppm/°C.

The temperature effects of the components described above are the same when the AD650 is configured for negative or bipolar input voltages, and for F/V conversion as well.

NONLINEARITY SPECIFICATION

The linearity error of the AD650 is specified by the end point method. That is, the error is expressed in terms of the deviation from the ideal voltage to frequency transfer relation after calibrating the converter at full scale and "zero". The nonlinearity will vary with the choice of one-shot capacitor and input resistor (see Figure 3). Verification of the linearity specification requires the availability of a switchable voltage source (or a DAC) having a linearity error below 20ppm, and the use of very long measurement intervals to minimize count uncertainties. Every AD650 is automatically tested for linearity, and it will not usually be necessary to perform this verification, which is both tedious and time consuming. If it is required to perform a nonlinearity test either as part of an incoming quality screening or as a final product evaluation, an automated "bench-top" tester would prove useful. Such a system based on the Analog Devices' LTS-2010 is described in Reference 2.

The voltage-to-frequency transfer relation is shown in Figure 9 with the nonlinearity exaggerated for clarity. The first step in determining nonlinearity is to connect the end points of the operating range (typically at 10mV and 10V) with a straight line. This straight line is then the ideal relationship which is desired from the circuit. The second step is to find the difference between this line and the actual response of the circuit at a few points between the end points – typically ten intermediate points will suffice. The difference between the actual and the ideal response is a frequency error measured in hertz. Finally, these frequency errors are normalized to the full scale frequency and expressed either as parts per million of full-scale (ppm) or parts per hundred of full scale (%). For example, on a 100kHz full scale, if the maximum frequency error is 5Hz, the nonlinearity would be specified as 50ppm or 0.005%. Typically on the 100kHz scale, the nonlinearity is positive and the maximum value occurs at about midscale (Figure 9a). At higher full scale frequencies, (500kHz to 1MHz), the nonlinearity becomes "S" shaped and the maximum value may be either positive or negative. Typically, on the 1MHz scale (R_{IN} = 16.9k, C_{OS} = 51pF) the nonlinearity is positive below about 2/3 scale and is negative above this point. This is shown graphically in Figure 9b.

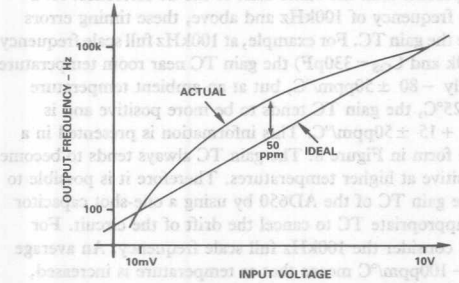

Figure 9a. Exaggerated Nonlinearity at 100kHz Full Scale

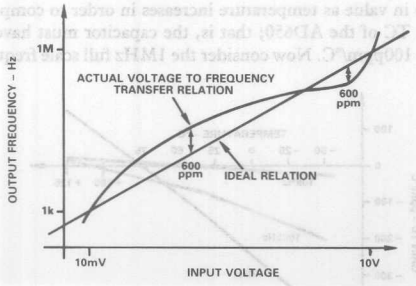

Figure 9b. Exaggerated Nonlinearity at 1MHz Full Scale

[2]"V-F Converters Demand Accurate Linearity Testing", by L. DeVito, (Electronic Design, March 4, 1982)

PSRR

The power supply rejection ratio is a specification of the change in gain of the AD650 as the power supply voltage is changed. The PSRR is expressed in units of parts-per-million change of the gain per percent change of the power supply – ppm/%. For example, consider a VFC with a 10 volt input applied and an output frequency of exactly 100kHz when the power supply potential is ±15 volts. Changing the power supply to ±12.5 volts is a 5 volt change out of 30 volts, or 16.7%. If the output frequency changes to 99.9kHz, the gain has changed 0.1% or 1000ppm. The PSRR is 1000ppm divided by 16.7% which equals 60ppm/%.

The PSRR of the AD650 is a function of the full scale operating frequency. At low full scale frequencies the PSRR is determined by the stability of the reference circuits in the device and can be very good. At higher frequencies there are dynamic errors which become more important than the static reference signals, and consequently the PSRR is not quite as good. The values of PSRR are typically 0 ±20ppm/% at 10kHz full scale frequency (R_{IN} = 40k, C_{OS} = 3300pF). At 100kHz (R_{IN} = 40k, C_{OS} = 330pF) the PSRR is typically +80 ±40ppm/%, and at 1MHz (R_{IN} = 16.9kΩ, C_{OS} = 51pF) the PSRR is +350 ±50ppm/%. This information is summarized graphically in Figure 10.

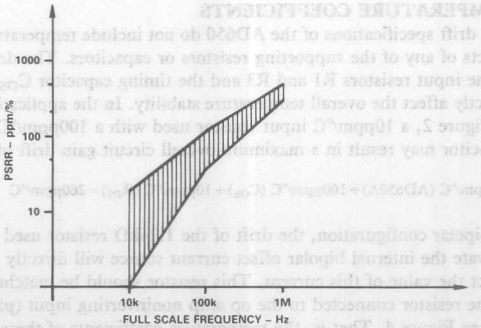

Figure 10. PSRR vs. Full Scale Frequency

OTHER CIRCUIT CONSIDERATIONS

The input amplifier connected to pins 1, 2 and 3 is not a standard operational amplifier. Rather, the design has been optimized for simplicity and high speed. The single largest difference between this amplifier and a normal op amp is the lack of an integrator (or level shift) stage. Consequently the voltage on the output (pin 1) must always be more positive than 2 volts below the inputs (pins 2 and 3). For example, in the F to V conversion mode, see Figure 6, the noninverting input of the op amp (pin 2) is grounded, which means that the output (pin 1) will not be able to go below −2 volts. Normal operation of the circuit as shown in the figure will never call for a negative voltage at the output but one may imagine an arrangement calling for a bipolar output voltage (say ±10 volts) by connecting an extra resistor from pin 3 to a positive voltage. This will not work.

Care should be taken under conditions where a high positive input voltage exists at or before power up. These situations can cause a latch up at the integrator output (pin 1). This is a non-destructive latch and, as such, normal operation can be restored by cycling the power supply. Latch up can be prevented by connecting two diodes (e.g., 1N914 or 1N4148) as shown in Figure 4 thereby preventing pin 1 from swinging below pin 2.

A second major difference is that the output will only sink 1mA to the negative supply. There is no pulldown stage at the output other than the 1mA current source used for the V to F conversion. The op amp will source a great deal of current from the positive supply, and it is internally protected by current limiting. The output of the op amp may be driven to within 3 volts of the positive supply when it is not sourcing external current. When sourcing 10mA the output voltage may be driven to within 6 volts of the positive supply.

A third difference between this op amp and a normal device is that the inverting input, pin 3, is bias current compensated and the noninverting input is not bias current compensated. The bias current at the inverting input is nominally zero, but may be as much as 20nA in either direction. The noninverting input typically has a bias current of 40nA that always flows into the node (an npn input transistor). Therefore, it is not possible to match input voltage drops due to bias currents by matching input resistors.

The op amp has provisions for trimming the input offset voltage. A potentiometer of 20kΩ is connected to pins 13 and 14 and the wiper is connected to the positive supply through a 250kΩ resistor. A potential of about 0.6 volt is established across the 250kΩ resistor, and the 3μA current is injected into the null pins. It is also possible to null the op amp offset voltage by using only one of the null pins and use a bipolar current either into or out of the null pin. The amount of current required will be very small – typically less than 3μA. This technique is shown in the applications section of this data sheet: the auto-zero circuit uses this technique.

The bipolar offset current is activated by connecting a 1.24kΩ resistor between pin 4 and the negative supply. The resultant current delivered to the op amp noninverting input is nominally 0.5mA and has a tolerance of ±10%. This current is then used to provide an offset voltage when pin 2 is tied to ground through a resistor. The 0.5mA which appears at pin 2 is also flowing through the 1.24kΩ resistor and this current may be measured by observing the voltage across the 1.24kΩ resistor. An external resistor is used to activate the bipolar offset current source to provide the lowest tolerance and temperature drift of the resultant offset voltage. It is possible to use other values of resistance between pin 4 and $-V_S$ to obtain a bipolar offset current different than 0.5mA. Figure 11 is a graph of the relationship between the bipolar offset current and the value of the resistor used to activate the source.

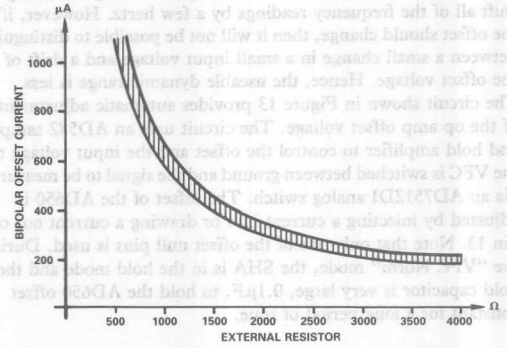

Figure 11. Bipolar Offset Current vs. External Resistor

APPLICATIONS

DIFFERENTIAL VOLTAGE-TO-FREQUENCY CONVERSION

The circuit of Figure 12 accepts a true floating differential input signal. The common mode input, V_{CM}, may be in the range +15 to −5 volts with respect to analog ground. The signal input, V_{IN}, may be ±5 volts with respect to the common mode input. Both inputs are low impedance: the source which drives the common mode input must supply the 0.5mA drawn by the bipolar offset current source and the source which drives the signal input must supply the integration current.

If less common mode voltage range is required, a lower voltage zener may be used. For example, if a 5 volt zener is used, the V_{CM} input may be in the range +10 to −5 volt. If the zener is not used at all, the common mode range will be ±5 volts with repect to analog ground. If no zener is used, the 10k pulldown resistor is not needed and the integrator output (pin 1) is connected directly to the comparator input (pin 9).

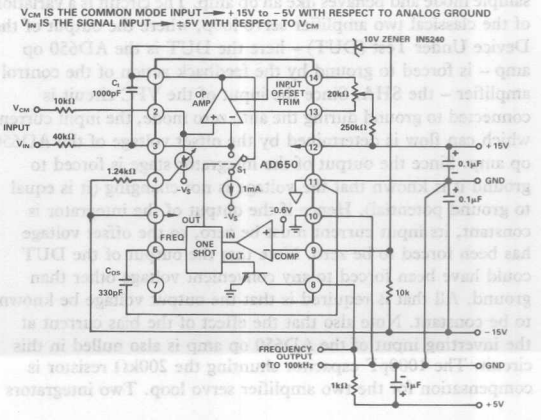

Figure 12. AD650 Differential Input

AUTO ZERO CIRCUIT

In order to exploit the full dynamic range of the AD650 VFC, very small input voltages will need to be converted. For example, a six decade dynamic range based on a full scale of 10 volts will require accurate measurement of signals down to 10μV. In these situations a well-controlled input offset voltage is imperative. A constant offset voltage will not affect dynamic range but simply shift all of the frequency readings by a few hertz. However, if the offset should change, then it will not be possible to distinguish between a small change in a small input voltage and a drift of the offset voltage. Hence, the useable dynamic range is less. The circuit shown in Figure 13 provides automatic adjustment of the op amp offset voltage. The circuit uses an AD582 sample and hold amplifier to control the offset and the input voltage to the VFC is switched between ground and the signal to be measured via an AD7512DI analog switch. The offset of the AD650 is adjusted by injecting a current into or drawing a current out of pin 13. Note that only one of the offset null pins is used. During the "VFC Norm" mode, the SHA is in the hold mode and the hold capacitor is very large, 0.1μF, to hold the AD650 offset constant for a long period of time.

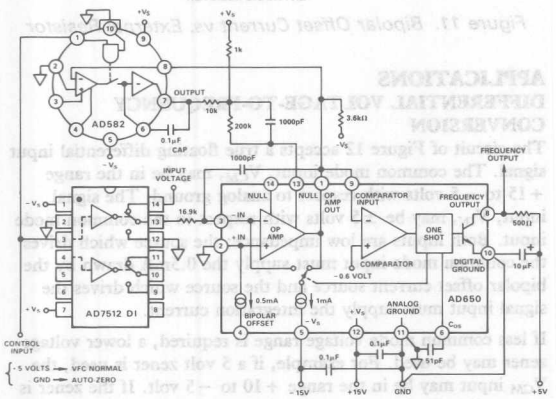

Figure 13. Auto-Zero Circuit for AD650 Voltage-to-Frequency Converter

When the circuit is in the "Auto Zero" mode the SHA is in sample mode and behaves like an op amp. The circuit is a variation of the classical two amplifier servo loop, where the output of the Device Under Test (DUT) – here the DUT is the AD650 op amp – is forced to ground by the feedback action of the control amplifier – the SHA. Since the input of the VFC circuit is connected to ground during the auto zero mode, the input current which can flow is determined by the offset voltage of the AD650 op amp. Since the output of the integrator stage is forced to ground it is known that the voltage is not changing (it is equal to ground potential). Hence if the output of the integrator is constant, its input current must be zero, so the offset voltage has been forced to be zero. Note that the output of the DUT could have been forced to any convenient voltage other than ground. All that is required is that the output voltage be known to be constant. Note also that the effect of the bias current at the inverting input of the AD650 op amp is also nulled in this circuit. The 1000pF capacitor shunting the 200kΩ resistor is compensation for the two amplifier servo loop. Two integrators in a loop requires a single zero for compensation. Note that the 3.6kΩ resistor from pin 1 of the AD650 to the negative supply is *not* part of the auto-zero circuit, but rather it is required for VFC operation at 1MHz.

PHASE LOCKED LOOP F/V CONVERSION

Although the F/V conversion technique shown in Figure 6 is quite accurate and uses only a few extra components, it is very limited in terms of signal frequency response and carrier feedthrough. If the carrier (or input) frequency changes instantaneously, the output cannot change very rapidly due to the integrator time constant formed by C_{INT} and R_{IN}. While it is possible to decrease the integrator time constant to provide faster settling of the F to V output voltage, the carrier feedthrough will then be larger. For signal frequency response in excess of 2kHz, a phase locked F/V conversion technique such as the one shown in Figure 14 is recommended.

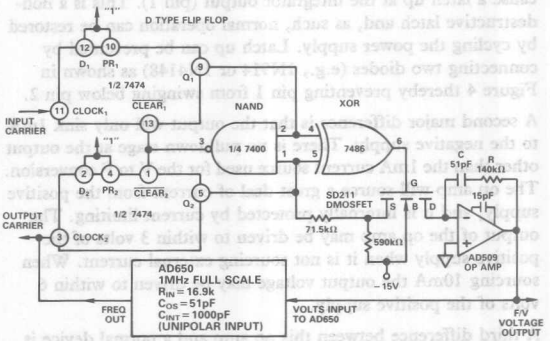

Figure 14. Phase Locked Loop F/V Conversion

In a phase locked loop circuit, the oscillator is driven to a frequency and phase equal to an input reference signal. In applications such as a synthesizer, the oscillator output frequency is first processed through a programmable "divide by N" before being applied to the phase detector as feedback. Here the oscillator frequency is forced to be equal to "N times" the reference frequency and it is this frequency output which is the desired output signal and not a voltage. In this case, the AD650 offers compact size and wide dynamic range.

In signal recovery applications of a PLL, the desired output signal is the voltage applied to the oscillator. In these situations a linear relationship between the input frequency and the output voltage is desired; the AD650 makes a superb oscillator for FM demodulation. The wide dynamic range and outstanding linearity of the AD650 VFC allow simple embodiment of high performance analog signal isolation or telemetry systems. The circuit shown in Figure 14 uses a digital phase detector which also provides proper feedback in the event of unequal frequencies. Such phase-frequency detectors (PFD's) are available in integrated form. For a full discussion of phase lock loop circuits see Reference 3.

An analysis of this circuit must begin at the 7474 dual D flip flop. When the input carrier matches the output carrier in both phase and frequency, the Q outputs of the flip flops will rise at exactly the same time. With two zero's, then two one's on the inputs of the exclusive or (XOR) gate, the output will remain low keeping the DMOS FET switched off. Also, the NAND gate will go low resetting the flip-flops to zero. Throughout the

[3]"Phase lock Techniques", by F.M. Gardner, 2nd Edition, 1979, John Wiley and Sons.

entire cycle just described, the DMOS integrator gate remained off, allowing the voltage at the integrator output to remain unchanged from the previous cycle. However, if the input carrier leads the output carrier by a few degrees, the XOR gate will be turned on for the small time span that the two signals are mismatched. Since Q_2 will be low during the mismatch time, a negative current will be fed into the integrator, causing its output voltage to rise. This in turn will increase the frequency of the AD650 slightly, driving the system towards synchronization. In a similar manner, if the input carrier lags the output carrier, the integrator will be forced down slightly to synchronize the two signals.

Using a mathematical approach, the $\pm 25\mu A$ pulses from the phase detector are incorporated into the phase detector gain, K_d.

$$K_d = \frac{25\mu A}{2\pi} = 4 \times 10^{-6} \quad amperes/radian \tag{9}$$

Also, the V/F converter is configured to produce 1MHz in response to a 10 volt input, so its gain K_o is:

$$K_o = \frac{2\pi \times 1 \times 10^6 Hz}{10V} = 6.3 \times 10^5 \quad \frac{radians}{volt \cdot sec} \tag{10}$$

The dynamics of the phase relationship between the input and output signals can be characterized as a second order system with natural frequency ω_n:

$$\omega_n = \sqrt{\frac{K_o K_d}{C}} \tag{11}$$

and damping factor

$$\zeta = \frac{R\sqrt{C\,K_o K_d}}{2} \tag{12}$$

For the values shown in Figure 14, these relations simplify to a natural frequency of 35kHz with a damping factor of 0.8.

For those desiring a simple approach to determining component values for other PLL frequencies and VFC full scale voltage, the following cookbook steps can be used:

1. Determine K_o (in units of radians per volt second) from the maximum input carrier frequency F_{max} (in hertz) and the maximum output voltage V_{max}.
$$K_o = \frac{2\pi \times F_{max}}{V_{max}} \tag{13}$$
2. Calculate a value for C based upon the desired loop bandwidth, f_n. Note that this is the desired frequency range of the output signal. The loop bandwidth (f_n) is *not* the maximum carrier frequency (f_{max}): the signal may be very narrow even though it is transmitted over a 1MHz carrier.
$$C = \frac{K_o}{f_n^2} \cdot 1 \times 10^{-7} \frac{V \cdot F}{Rad \cdot sec} \quad \begin{matrix} C \text{ units FARADS} \\ f_n \text{ units HERTZ} \\ K_o \text{ units RAD/VOLT•SEC} \end{matrix} \tag{14}$$
3. Calculate R to yield a damping factor of approximately 0.8 using this equation:
$$R = \frac{f_n}{K_o} \cdot 2.5 \times 10^6 \frac{Rad \cdot \Omega}{V} \quad \begin{matrix} R \text{ units OHMS} \\ f_n \text{ units HERTZ} \\ K_o \text{ units RAD/VOLT•SEC} \end{matrix} \tag{15}$$

If in actual operation the PLL overshoots or hunts excessively before reaching a final value, the damping factor may be raised by increasing the value of R. Conversely, if the PLL is overdamped, a smaller value of R should be used.

PLL PERFORMANCE

The performance of the PLL circuit is demonstrated by the system shown in Figure 15; an analog signal is converted into a frequency, and then this frequency is converted back into an analog voltage by the PLL.

The source of the frequency input signal used to drive the PLL is an AD650 with two separate inputs: one for dc to set the carrier frequency, and one for ac to establish a modulation. Note how the summing junction input to the AD650 allows such flexibility. The output frequency is then relayed to the

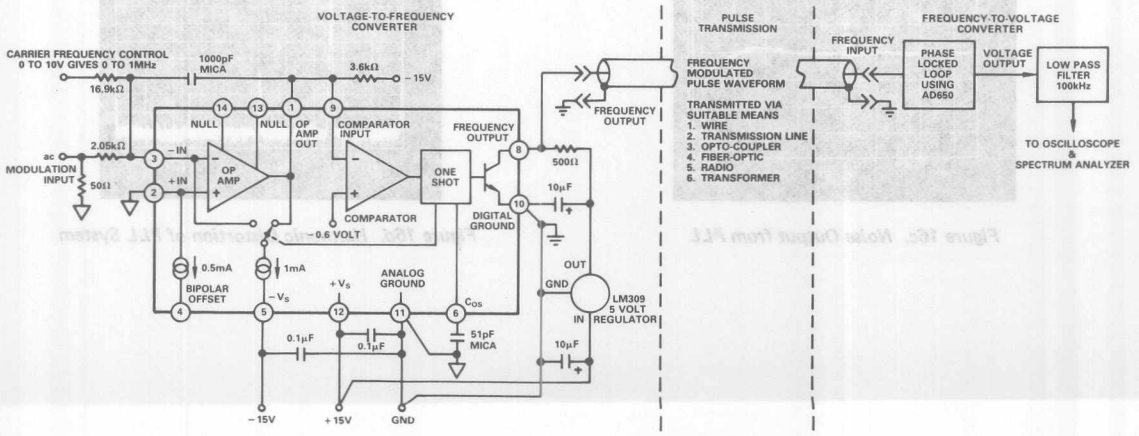

Figure 15.

PLL via a jumper cable. The signal at this point is a 5 volt digital pulse train and as such may be transmitted in any fashion suitable to the application at hand. For example, galvanic isolation is achieved with a simple transformer or opto-isolator; extremely high voltage isolation or transmission through severe RF environments can be accomplished with a fiber-optic link; telemetry can be accomplished with a radio link. The actual method of conveying the pulses is not crucial to the system performance. The PLL is the circuit shown in Figure 14, and the filter shown on the output signal is simply to attenuate carrier feedthrough to allow easy interpretation of the signal with an oscilloscope and spectrum analyzer.

The step response of the system is shown in Figure 16a. The signal output is swinging between 5 volts and 10 volts, for an input step of 500kHz to 1MHz. Note that the AD650 is actually overshooting to 1.1MHz and the response remains well controlled. Note the slight irregularity during the transition: this is caused by cycleslipping during the slew where feedback is lost temporarily and the PLL actually loses phase lock. The frequency response of the system when driven with sinewave excitation is shown in Figure 16b. Here the output level is set to 2 volts peak to peak, and the carrier is 800kHz. Note that the −3dB bandwidth is about 70kHz, which is consistent with a damping factor of 0.8 and a natural frequency of 35kHz[4]. When an unmodulated carrier is applied to the PLL, the noise that appears at the output determines the dynamic range of the system. The spectrum of the noise at the output of the PLL is shown in Figure 16c. By comparing this with Figure 16b, the dynamic range of the system is seen to be 80dB. The harmonic distortion of the system is shown in Figure 16d. The output is a 2V p-p sinewave at 5kHz, and the amplitude of the first harmonic is seen to be 48dB below the fundamental. The harmonic distortion can be improved to the level of 60dB by reducing the amplitude of the modulation, but this is at the expense of dynamic range since the intensity of the noise floor remains constant.

Monolithic Synchronous Voltage-to-Frequency Converter

AD652

FEATURES

- Full-Scale Frequency (Up to 2MHz) Set by External System Clock
- Extremely Low Linearity Error (0.005% max at 1MHz FS, 0.02% max at 2MHz FS)
- No Critical External Components Required
- Accurate 5V Reference Voltage
- Low Drift (25ppm/°C max)
- Dual or Single Supply Operation
- Voltage or Current Input
- MIL-STD-883 Compliant Versions Available

FUNCTIONAL BLOCK DIAGRAM

PRODUCT DESCRIPTION

The AD652 Synchronous Voltage-to-Frequency Converter (SVFC) is a powerful building block for precision analog-to-digital conversion, offering typical nonlinearity of 0.002% (0.005% maximum) at a 100kHz output frequency. The inherent monotonicity of the transfer function and wide range of clock frequencies allows the conversion time and resolution to be optimized for specific applications.

The AD652 uses a variation of the popular charge-balancing technique to perform the conversion function. The AD652 uses an external clock to define the full-scale output frequency, rather than relying on the stability of an external capacitor. The result is a more stable, more linear transfer function, with significant application benefits in both single- and multi-channel systems.

Gain drift is minimized using a precision low-drift reference and low-TC on-chip thin-film scaling resistors. Furthermore, the initial gain error is reduced to less than 0.5% by the use of laser-wafer-trimming.

The analog and digital sections of the AD652 have been designed to allow operation from a single-ended power source, simplifying its use with isolated power supplies.

The AD652 is available in five performance grades. The 20-pin PLCC packaged JP and KP grades are specified for operation over the 0 to +70°C commercial temperature range. The 16-pin cerdip-packaged AQ and BQ grades are specified for operation over the −40°C to +85°C industrial temperature range, and the AD652SQ is available for operation over the full −55°C to +125°C extended temperature range.

PRODUCT HIGHLIGHTS

1. The use of an external clock to set the full-scale frequency allows the AD652 to achieve linearity and stability far superior to other monolithic VFCs. By using the same clock to drive the AD652 and (through a suitable divider) also set the counting period, conversion accuracy is maintained independent of variations in clock frequency.
2. The AD652 Synchronous VFC requires only a single external component (a noncritical integrator capacitor) for operation.
3. The AD652 includes a buffered, accurate 5V reference which is available to the user.
4. The clock input of the AD652 is TTL and CMOS compatible and can also be driven by sources referred to the negative power supply. The flexible open-collector output stage provides sufficient current sinking capability for TTL and CMOS logic, as well as for optical couplers and pulse transformers. A capacitor-programmable one-shot is provided for selection of optimum output pulse width for power reduction.
5. The AD652 can also be configured for use as a synchronous F/V converter for isolated analog signal transmission.
6. The AD652 is available in versions compliant with MIL-STD-883. Refer to the Analog Devices Military Products Databook or current AD652/883B data sheet for detailed specifications.

DEFINITIONS OF SPECIFICATIONS

GAIN ERROR – The gain of a voltage-to-frequency converter is that scale factor setting that provides the nominal conversion relationship, e.g. 1MHz full scale. The "gain error" is the difference in slope between the actual and ideal transfer functions for the V-F converter.

LINEARITY ERROR – The "linearity error" of a V-F is the deviation of the actual transfer function from a straight line passing through the endpoints of the transfer function.

GAIN TEMPERATURE COEFFICIENT – The gain temperature coefficient is the rate of change in full-scale frequency as a function of the temperature from +25°C to T_{min} or T_{max}.

THEORY OF OPERATION

A synchronous VFC is similar to other voltage-to-frequency converters in that an integrator is used to perform a charge-balance of the input signal with an internal reference current. However, rather than using a one-shot as the primary timing element which requires a high quality and low drift capacitor, a synchronous voltage-to-frequency converter (SVFC) uses an external clock; this allows the designer to determine the system stability and drift based upon the external clock selected. A crystal oscillator may also be used if desired.

The SVFC architecture provides other system advantages besides low drift. If the output frequency is measured by counting pulses gated to a signal which is derived from the clock, the clock stability is unimportant and the device simply performs as a voltage controlled frequency divider, producing a high resolution A/D. If a large number of inputs must be monitored simultaneously in a system, the controlled timing relationship between the frequency output pulses and the user supplied clock greatly simplifies this signal acquisition. Also, if the clock signal is provided by a VFC, then the output frequency of the SVFC will be proportional to the product of the two input voltages. Hence, multiplication and A-to-D conversion on two signals are performed simultaneously.

The pinouts of the AD652 SVFC are shown in Figure 1. A block diagram of the device configured as a SVFC, along with various system waveforms, is shown in Figure 2.

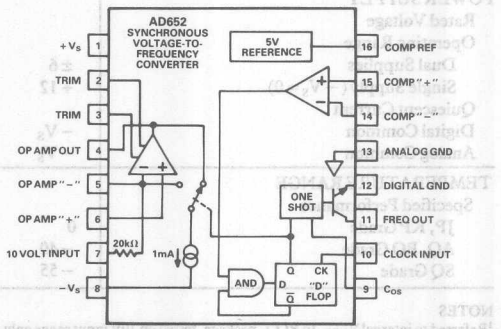

Figure 1a. AD652 Cerdip Pin Configuration

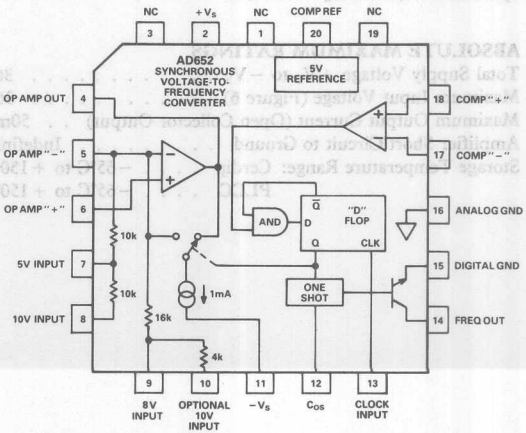

Figure 1b. AD652 PLCC Pin Configuration

Figure 2 shows the typical up-and-down ramp integrator output of a charge-balance VFC. After the integrator output has crossed the comparator threshold and the output of the AND gate has gone high, nothing happens until a negative edge of the clock comes along to transfer the information to the output of the D-FLOP. At this point, the clock level is low, so the latch does not change state. When the clock returns high, the latch output goes high and drives the switch to reset the integrator. At the same time the latch drives the AND gate to a low output state. On the very next negative edge of the clock the low output state of the AND gate is transferred to the output of the D-FLOP and then when the clock returns high, the latch output goes low and drives the switch back into the Integrate Mode. At the same time the latch drives the AND gate to a mode where it will truthfully relay the information presented to it by the comparator.

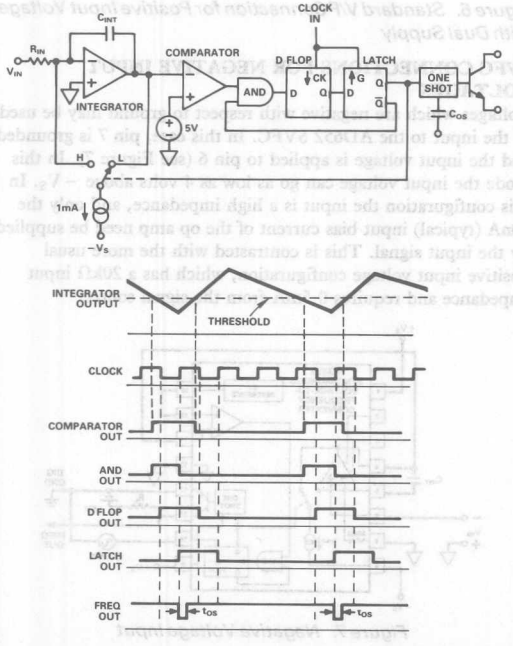

Figure 2. AD652 Block Diagram and System Waveforms

Since the reset pulses applied to the integrator are exactly one clock period long, the only place where drift can occur is in a variation of the symmetry of the switching speed with temperature. Since each reset pulse is identical to every other, the AD652 SVFC produces a very linear voltage to frequency transfer relation. Also, since all of the reset pulses are gated by the clock, there are no problems with dielectric absorption causing the duration of a reset pulse to be influenced by the length of time since the last reset.

Referring to Figure 2, it can be seen that the period between output pulses is constrained to be an exact multiple of the clock period. Consider an input current of exactly one quarter of the value of the reference current. In order to achieve a charge balance, the output frequency will equal the clock frequency divided by four; one clock period for reset and three clock periods of integrate. This is shown in Figure 3. If the input current is increased by a very small amount, the output frequency should also increase by a very small amount. Initially, however, no output change is observed for a very small increase in the input current. The output frequency continues to run at one quarter of the clock, delivering an average of 250μA to the summing junction. Since the input current is slightly larger than this, charge accumulates in the integrator and the sawtooth signal starts to drift downward. As the integrator sawtooth drifts down, the comparator threshold is crossed earlier and earlier in each successive cycle, until finally, a whole cycle is lost. When the cycle is lost, the Integrate Phase lasts for two periods of the clock instead of the usual three periods. Thus, among a long string of divide-by-four's an occasional divide-by-three occurs; the average of the output frequency is very close to one quarter of the clock, but the instantaneous frequency can be very different.

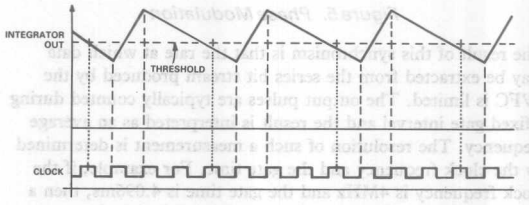

Figure 3. Integrator Output for $I_{IN} = 250\mu A$

Because of this, it is very difficult to observe the waveform on an oscilloscope. During all of this time, the signal at the output of the integrator is a sawtooth wave with an envelope which is also a sawtooth. This is shown in Figure 4.

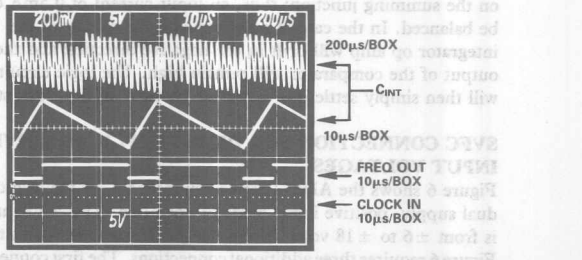

Figure 4. Integrator Output for I_{IN} Slightly Greater than 250μA

Another way to view this is that the output is a frequency of approximately one quarter of the clock that has been phase modulated. A constant frequency can be thought of as accumulating phase linearly with time at a rate equal to $2\pi f$ radians per second. Hence, the average output frequency which is slightly in excess of a quarter of the clock will require phase accumulation at a certain rate. However, since the SVFC is running at exactly one quarter of the clock, it will not accumulate enough phase (see Figure 5). When the difference between the required phase (average frequency) and the actual phase equals 2π, a step in phase is taken where the deficit is made up instantaneously. The output frequency is then a steady carrier which has been phase modulated by a sawtooth signal (see Figure 5). The period of the sawtooth phase modulation is the time required to accumulate a 2π difference in phase between the required average

frequency and one quarter of the clock frequency. The amplitude of the sawtooth phase modulation is 2π.

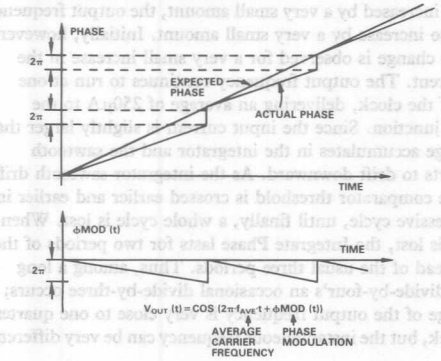

Figure 5. Phase Modulation

The result of this synchronism is that the rate at which data may be extracted from the series bit stream produced by the SVFC is limited. The output pulses are typically counted during a fixed gate interval and the result is interpreted as an average frequency. The resolution of such a measurement is determined by the clock frequency and the gate time. For example, if the clock frequency is 4MHz and the gate time is 4.096ms, then a maximum count of 8,192 is produced by a full-scale frequency of 2MHz. Thus, the resolution is 13 bits.

OVERRANGE

Since each reset pulse is only one clock period in length, the full-scale output frequency is equal to one-half the clock frequency. At full scale the current steering switch spends half of the time on the summing junction; thus, an input current of 0.5mA can be balanced. In the case of an overrange, the output of the integrator op amp will drift in the negative direction and the output of the comparator will remain high. The logic circuits will then simply settle into a "divide-by-two" of the clock state.

SVFC CONNECTION FOR DUAL SUPPLY, POSITIVE INPUT VOLTAGES

Figure 6 shows the AD652 connection scheme for the traditional dual supply, positive input mode of operation. The $\pm V_S$ range is from ± 6 to ± 18 volts. When $+V_S$ is lower than 9.0 volts, Figure 6 requires three additional connections. The first connection is to short pin 13 to pin 8 (Analog Ground to $-V_S$) and add a pull-up resistor to $+V_S$ (as shown in Figure 15). The pull-up resistor is determined by the following equation:

$$R_{PULLUP} = \frac{2\,V_S - 5V}{500\mu A}$$

These connections will ensure proper operation of the 5V reference. Tie pin 16 to pin 6 (as shown in Figure 15) to ensure that the integrator output ramps down far enough to trip the comparator.

The cerdip packaged AD652 accepts either a 0 to 10V or 0 to 0.5mA full-scale input signal. The temperature drift of the AD652 is specified for a 0 to 10V input range using the internal 20kΩ resistor. If a current input is used, the gain drift will be degraded by a maximum of 100ppm/°C (the TC of the 20kΩ resistor). If an external resistor is connected to pin 5 to establish a different input voltage range, drift will be induced to the extent that the external resistor's TC differs from the TC of the internal resistor. The external resistor used to establish a different input voltage range should be selected as to provide a full-scale current of 0.5mA (i.e., 10kΩ for 0 to 5V).

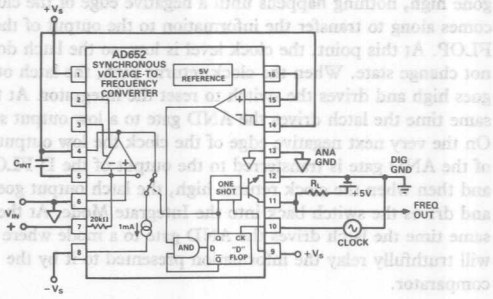

Figure 6. Standard V/F Connection for Positive Input Voltage with Dual Supply

SVFC CONNECTIONS FOR NEGATIVE INPUT VOLTAGES

Voltages which are negative with respect to ground may be used as the input to the AD652 SVFC. In this case, pin 7 is grounded and the input voltage is applied to pin 6 (see Figure 7). In this mode the input voltage can go as low as 4 volts above $-V_S$. In this configuration the input is a high impedance, and only the 20nA (typical) input bias current of the op amp need be supplied by the input signal. This is contrasted with the more usual positive input voltage configuration, which has a 20kΩ input impedance and requires 0.5mA from the signal source.

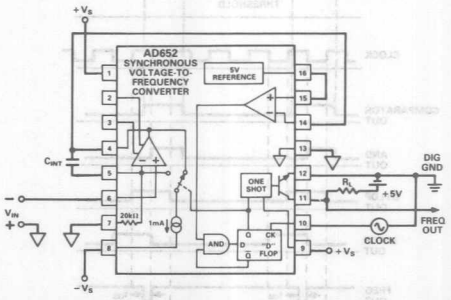

Figure 7. Negative Voltage Input

SVFC CONNECTION FOR BIPOLAR INPUT VOLTAGES

A bipolar input voltage of $\pm 5V$ can be accommodated by injecting a 250μA current into pin 5. This is shown in Figure 8a. A $-5V$ signal will then provide a zero sum current at the integrator summing junction which will result in a zero output frequency, while a $+5V$ signal will provide a 0.5mA (full-scale) sum current which will result in the full-scale output frequency.

The use of an external resistor to inject the offset current will have some effect on the bipolar offset temperature coefficient. The ideal transfer curve with bipolar inputs is shown in Figure 8b. The user actually has four options to use in injecting the bipolar offset current into the inverting input of the op amp: 1) use an external resistor for R_{OS} and the internal 20k resistor for R_{IN} (as shown in Figure 8a); 2) use the internal 20k resistor as R_{OS} and an external R_{IN}; 3) use two external resistors; 4) use two internal resistors for R_{IN} and R_{OS} (available on PLCC version only).

Option #4 provides the closest to the ideal transfer function as diagrammed in Figure 8b. Figure 8c shows the effects on the transfer relation of the other three options. In the first case, the slope of the transfer function is unchanged with temperature. However, V_{ZERO} (the input voltage required to produce an output frequency of 0Hz) and F_{ZERO} (the output frequency when V_{IN} = 0V) changes as the transfer function is displaced parallel to the voltage axis with temperature. In the second case, F_{ZERO} remains constant, but V_{ZERO} changes as the transfer function rotates about F_{ZERO} with temperature changes. In the third case, with two external resistors, the V_{ZERO} point remains invariant while the slope and offset of the transfer function change with temperature. If selecting this third option, the user should select low drift, matched resistors.

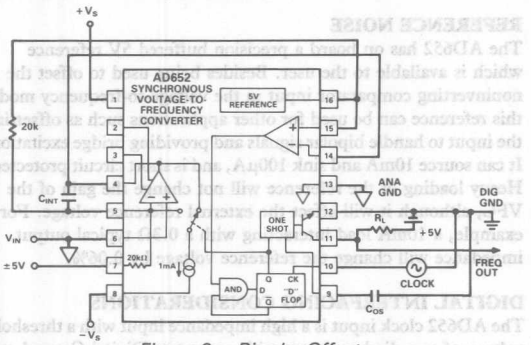

Figure 8a. Bipolar Offset

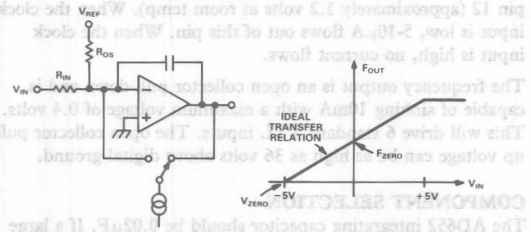

Figure 8b. Ideal Bipolar Input Transver Curve Over Temperature

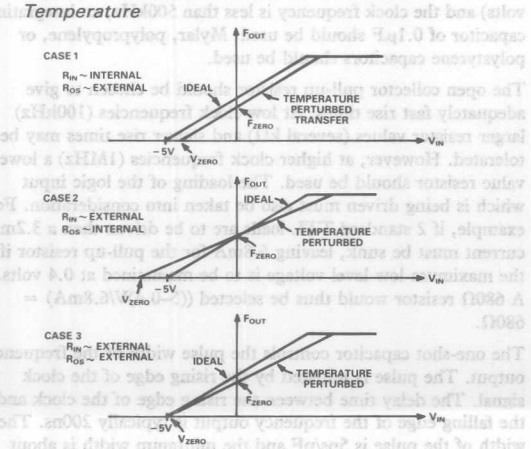

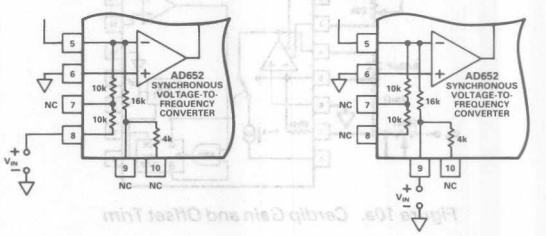

Figure 8c. Actual Bipolar Input Transfer Over Temperature

PLCC CONNECTIONS

The PLCC packaged AD652 offers additional input resistors not found on the cerdip-packaged device. These resistors provide the user with additional input voltage ranges. Besides the 10V range available using the on-chip resistor in the cerdip part, the PLCC device also offers 8V and 5V ranges. Figures 9a-9c show the proper connections for these ranges with positive input voltages. For negative input voltages, the appropriate resistor should be tied to analog ground and the input voltage should be applied to pin 6, the "+" input of the op amp.

Bipolar input voltages can be accommodated by injecting a 250μA into pin 5 with the use of the 5V reference and the input resistors. For ±5V or ±2.5V range the reference output, pin 20, should be tied to pin 10. The input signal should then be applied to pin 8 for a ±5V signal and pin 7 for a ±2.5V signal. The input connections for a ±5V range are shown in Figure 9d. For a ±4V range, the input signal should be applied to pin 9, and pin 20 should be connected to pin 8.

c. PLCC 0 to +5V Input *d. PLCC ±5V Input*

Figure 9.

GAIN AND OFFSET CALIBRATION

The gain error of the AD652 is laser trimmed to within ±0.5%. If higher accuracy is required, the internal 20kΩ resistor must be shunted with a 2MΩ resistor to produce a parallel equivalent which is 1% lower in value than the nominal 20kΩ. Full scale adjustment is then accomplished using a 500Ω series trimmer. See Figures 10a and 10b. When negative input voltages are used, this 500Ω trimmer will be tied to ground and pin 6 will be the input pin.

This gain trim should be done with an input voltage of 9V, and the output frequency should be adjusted to exactly 45% of the clock frequency. Since the device settles into a divide-by-two mode for an input overrange condition, adjusting the gain with a 10V input is impractical; the output frequency would be exactly one-half the clock frequency if the gain were too high and would not change with adjustment until the exact proper scale factor was achieved. Hence, the gain adjustment should be done with a 9V input.

scheme shown in Figures 10a for the cerdip packaged device and Figure 10b for the PLCC packaged device. One way of trimming the offset is by grounding pin 7 (8) of the cerdip (PLCC) packaged device and observing the waveform at pin 4. If the offset voltage of the op amp is positive, then the integrator will have saturated and the voltage will be at the positive rail. If the offset voltage is negative, then there will be a small effective input current that will cause the AD652 to oscillate and a sawtooth waveform will be observed at pin 4. The trimpot should be adjusted until the downward slope of this sawtooth becomes very slow, down to a frequency of 1Hz or less. In an analog-to-digital conversion application, an easier way to trim the offset is to apply a small input voltage, such as 0.01% of the full-scale voltage, and adjust the trimpot until the correct digital output is reached.

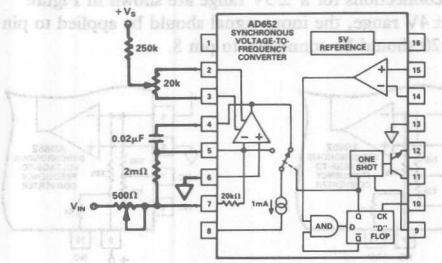

Figure 10a. Cerdip Gain and Offset Trim

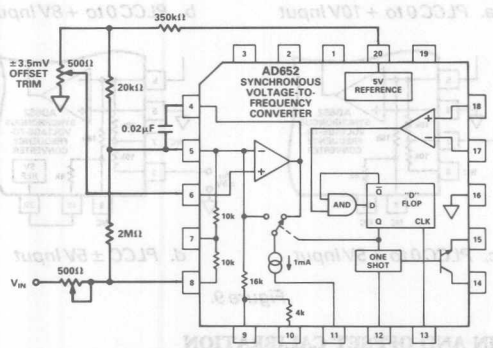

Figure 10b. PLCC Gain and Offset Trim

GAIN PERFORMANCE

The AD652 gain error is specified as the difference in slope between the actual and the ideal transfer function over the full-scale frequency range. Figure 11 shows a plot of the typical gain error changes vs. the clock input frequency, normalized to 100kHz. If after using the AD652 with a full-scale clock frequency of 100kHz it is decided to reduce the necessary gating time by increasing the clock frequency, this plot shows the typical gain changes normalized to the original 100kHz gain.

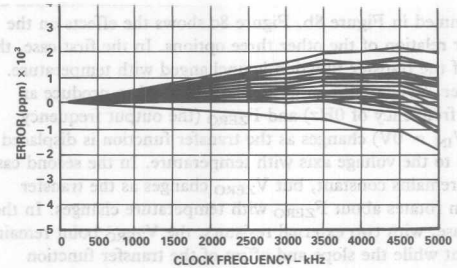

Figure 11. Gain vs. Clock Input

REFERENCE NOISE

The AD652 has on board a precision buffered 5V reference which is available to the user. Besides being used to offset the noninverting comparator input in the voltage-to-frequency mode, this reference can be used for other applications such as offsetting the input to handle bipolar signals and providing bridge excitation. It can source 10mA and sink 100μA, and is short circuit protected. Heavy loading of the reference will not change the gain of the VFC, although it will affect the external reference voltage. For example, a 10mA load interacting with a 0.3Ω typical output impedance will change the reference voltage by 0.06%.

DIGITAL INTERFACING CONSIDERATIONS

The AD652 clock input is a high impedance input with a threshold voltage of two diode voltages with respect to Digital Ground at pin 12 (approximately 1.2 volts at room temp). When the clock input is low, 5-10μA flows out of this pin. When the clock input is high, no current flows.

The frequency output is an open collector pull-down and is capable of sinking 10mA with a maximum voltage of 0.4 volts. This will drive 6 standard TTL inputs. The open collector pull up voltage can be as high as 36 volts above digital ground.

COMPONENT SELECTION

The AD652 integrating capacitor should be 0.02μF. If a large amount of normal mode interference is expected (more than 0.1 volts) and the clock frequency is less than 500kHz, an integrating capacitor of 0.1μF should be used. Mylar, polypropylene, or polystyrene capacitors should be used.

The open collector pull-up resistor should be chosen to give adequately fast rise times. At low clock frequencies (100kHz) larger resistor values (several kΩ) and slower rise times may be tolerated. However, at higher clock frequencies (1MHz) a lower value resistor should be used. The loading of the logic input which is being driven must also be taken into consideration. For example, if 2 standard TTL loads are to be driven then a 3.2mA current must be sunk, leaving 6.8mA for the pull-up resistor if the maximum low level voltage is to be maintained at 0.4 volts. A 680Ω resistor would thus be selected ((5–0.4)V/6.8mA) = 680Ω.

The one-shot capacitor controls the pulse width of the frequency output. The pulse is initiated by the rising edge of the clock signal. The delay time between the rising edge of the clock and the falling edge of the frequency output is typically 200ns. The width of the pulse is 5ns/pF and the minimum width is about 200ns with pin 9 floating. If the one-shot period is accidentally chosen longer than the clock period, the width of the pulse will

default to equal the clock period. The one-shot can be disabled by connecting pin 9 to $+V_S$ (Figure 12); the output pulse width will then be equal to the clock period. The one-shot is activated (Figure 13) by connecting a capacitor from pin 9 to $+V_S$, $-V_S$, or Digital Ground($+V_S$ is preferred).

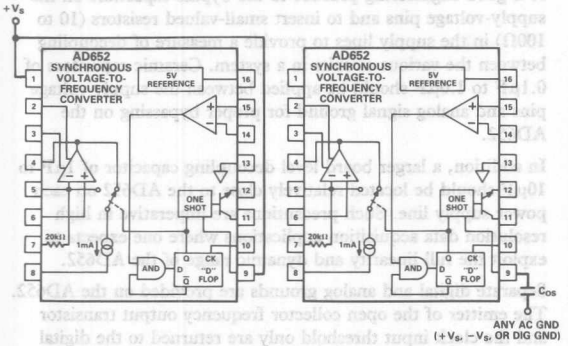

Figure 12. One Shot Disabled

Figure 13. One Shot Enabled

DIGITAL GROUND

Digital Ground can be at any potential between $-V_S$ and ($+V_S$ -4 volts). This can be very useful in a system with derived grounds rather than stiff supplies. For example, in a small isolated power circuit, often only a single supply is generated and the "ground" is set by a divider tap. Such a ground cannot handle the large currents associated with digital signals. With the AD652 SVFC, it is possible to connect the DIG GND to $-V_S$ for a solid logic reference, as shown in Figure 14.

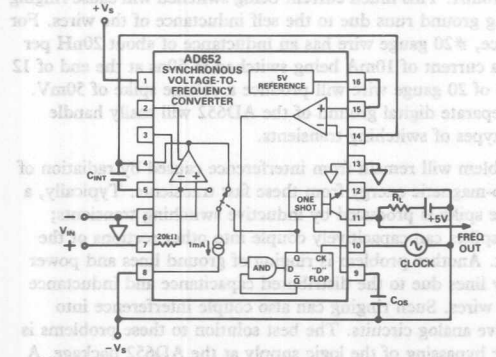

Figure 14. Digital GND at $-V_S$

SINGLE SUPPLY OPERATION

In addition to the Digital Ground being connected to $-V_S$, it is also possible to connect Analog Ground to $-V_S$ of the AD652. Hence, the device is truly operating from a single supply voltage that can range from $+12V$ to $+36V$. This is shown in Figure 15 for a positive voltage input and Figure 16 for a negative voltage input.

In Figure 15, the comparator reference is used as a derived ground, and the input voltage is referred to this point as well as the op amp common mode (pin 6 is tied to pin 16). Since the input signal source must drive 0.5mA of full-scale signal current into pin 7, it must also draw the exact same current from the input reference potential. This current will thus be provided by the 5V reference.

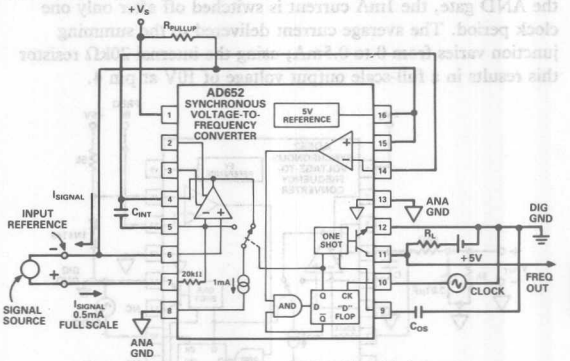

Figure 15. Single Supply Positive Voltage Input

In the single supply operation mode, an external resistor, R_{PULLUP}, is necessary between the power supply, $+V_S$, and the 5V reference output. This resistor should be selected such that a current of approximately 500μA flows during operation. For example, with a power supply voltage of $+15V$, a 20kΩ resistor would be selected ((15V − 5V)/500μA = 20kΩ).

Figure 16 shows the negative voltage input configuration for use of the AD652 in the single supply mode. In this mode the signal source is driving the "+" input of the op amp which requires only 20nA (typical), rather than the 0.5mA required in the positive input voltage configuration. The voltage at pin 6 may go as low as 4 volts above ground ($-V_S$, pin 8). Since the input reference is 5.0 volts above ground, this leaves a 1V window for the input signal. In order to drive the integrating capacitor with a 0.5mA full-scale current, it is necessary to provide an external 2kΩ resistor. This results in a 2kΩ resistor and a 1V input range. The external 2kΩ resistor should be a low-TC metal-film type for lowest drift degradation.

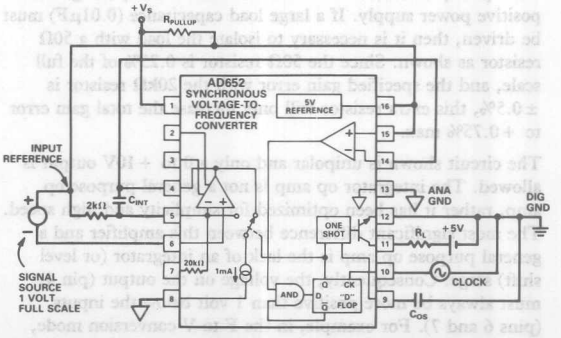

Figure 16. Single Supply Negative Voltage Input

FREQUENCY-TO-VOLTAGE CONVERTER

The AD652 SVFC also works as a frequency-to-voltage converter. Figure 17 shows the connection diagram for F/V conversion. In this case the "−" input of the comparator is fed the input pulses. Either comparator input may be used so that an input pulse of either polarity may be applied to the F/V. In Figure 17 the "+" input is tied to a 1.2V reference and low level TTL pulses are used as the frequency input. The pulse must be low

on the falling edge of the clock. On the subsequent rising edge the 1mA current source is switched to the integrator summing junction and ramps up the voltage at pin 4. Due to the action of the AND gate, the 1mA current is switched off after only one clock period. The average current delivered to the summing junction varies from 0 to 0.5mA; using the internal 20kΩ resistor this results in a full-scale output voltage of 10V at pin 4.

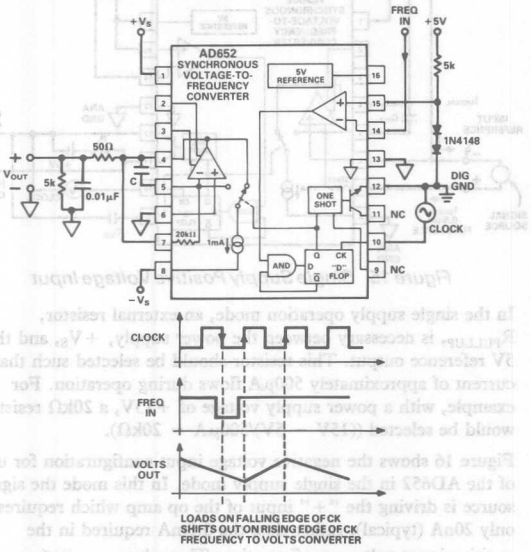

Figure 17. Frequency-to-Voltage Converter

The frequency response of the circuit is determined by the capacitor; the −3dB frequency is simply the RC time constant. A tradeoff exists between ripple and response. If low ripple is desired, a large value capacitor must be used (1μF), if fast response is needed, a small capacitor is used (1nF minimum).

The op amp can drive a 5kΩ resistor load to 10V, using a 15V positive power supply. If a large load capacitance (0.01μF) must be driven, then it is necessary to isolate the load with a 50Ω resistor as shown. Since the 50Ω resistor is 0.25% of the full scale, and the specified gain error with the 20kΩ resistor is ±0.5%, this extra resistor will only increase the total gain error to +0.75% max.

The circuit shown is unipolar and only a 0 to +10V output is allowed. The integrator op amp is not a general purpose op amp, rather it has been optimized for simplicity and high speed. The most significant difference between this amplifier and a general purpose op amp is the lack of an integrator (or level shift) stage. Consequently, the voltage on the output (pin 4) must always be more positive than 1 volt below the inputs (pins 6 and 7). For example, in the F-to-V conversion mode, the noninverting input of the op amp (pin 6) is grounded which means that the output (pin 4) cannot go below −1 volt. Normal operation of the circuit as shown will never call for a negative voltage at the output.

A second difference between this op amp and a general purpose amplifier is that the output will only sink 1.5mA to the negative supply. The only pulldown other than the 1mA current used for voltage-to-frequency conversion is a 0.5mA source. The op amp will source a great deal of current from the positive supply, and it is internally protected by current limiting. The output of the op amp may be driven to within 4 volts of the positive supply when not sourcing external current. When sourcing 10mA, the output voltage may be driven to within 6 volts of the positive supply.

DECOUPLING AND GROUNDING

It is good engineering practice to use bypass capacitors on the supply-voltage pins and to insert small-valued resistors (10 to 100Ω) in the supply lines to provide a measure of decoupling between the various circuits in a system. Ceramic capacitors of 0.1μF to 1.0μF should be applied between the supply-voltage pins and analog signal ground for proper bypassing on the AD652.

In addition, a larger board level decoupling capacitor of 1μF to 10μF should be located relatively close to the AD652 on each power supply line. Such precautions are imperative in high resolution data acquisition applications where one expects to exploit the full linearity and dynamic range of the AD652.

Separate digital and analog grounds are provided on the AD652. The emitter of the open collector frequency output transistor and the clock input threshold only are returned to the digital ground. Only the 5V reference is connected to analog ground. The purpose of the two separate grounds is to allow isolation between the high precision analog signals and the digital section of the circuitry. Much noise can be tolerated on the digital ground without affecting the accuracy of the VFC. Such ground noise is inevitable when switching the large currents associated with the frequency output signal.

At high full-scale frequencies, it is necessary to use a pull-up resistor of about 500Ω in order to get the rise time fast enough to provide well defined output pulses. This means that from a 5 volt logic supply, for example, the open collector output will draw 10mA. This much current being switched will cause ringing on long ground runs due to the self inductance of the wires. For instance, #20 gauge wire has an inductance of about 20nH per inch; a current of 10mA being switched in 50ns at the end of 12 inches of 20 gauge wire will produce a voltage spike of 50mV. The separate digital ground of the AD652 will easily handle these types of switching transients.

A problem will remain from interference caused by radiation of electro-magnetic energy from these fast transients. Typically, a voltage spike is produced by inductive switching transients; these spikes can capacitively couple into other sections of the circuit. Another problem is ringing of ground lines and power supply lines due to the distributed capacitance and inductance of the wires. Such ringing can also couple interference into sensitive analog circuits. The best solution to these problems is proper bypassing of the logic supply at the AD652 package. A 1μF to 10μF tantalum capacitor should be connected directly to the supply side of the pull-up resistor and to the digital ground, pin 12. The pull-up resistor should be connected directly to the frequency output, pin 11. The lead lengths on the bypass capacitor and the pull-up resistor should be as short as possible. The capacitor will supply (or absorb) the current transients, and large ac signals will flow in a physically small loop through the capacitor, pull-up resistor, and frequency output transistor. It is important that the loop be physically small for two reasons: first, there is less inductance if the wires are short, and second, the loop will not radiate RFI efficiently.

The digital ground (pin 12) should be separately connected to the power supply ground. Note that the leads to the digital power supply are only carrying dc current. There may be a dc

ground drop due to the difference in currents returned on the analog and digital grounds. This will not cause a problem. These features greatly ease power distribution and ground management in large systems. Proper technique for grounding requires separate digital and analog ground returns to the power supply. Also, the signal ground must be referred directly to analog ground (pin 6) at the package. More information on proper grounding and reduction of interference can be found in reference 1.

FREQUENCY OUTPUT MULTIPLIER

The AD652 can serve as a frequency output multiplier when used in conjunction with a standard voltage-to-frequency converter. Figure 18 shows the low cost AD654 VFC being used as the clock input to the AD652. Also shown is a second AD652 in the F/V mode. The AD654 is set up to produce an output frequency of 0-500kHz for an input voltage (V_1) range of 0-10V. The use of R4, C1, and the XOR gate doubles this output frequency from 0-500kHz to 0-1MHz.

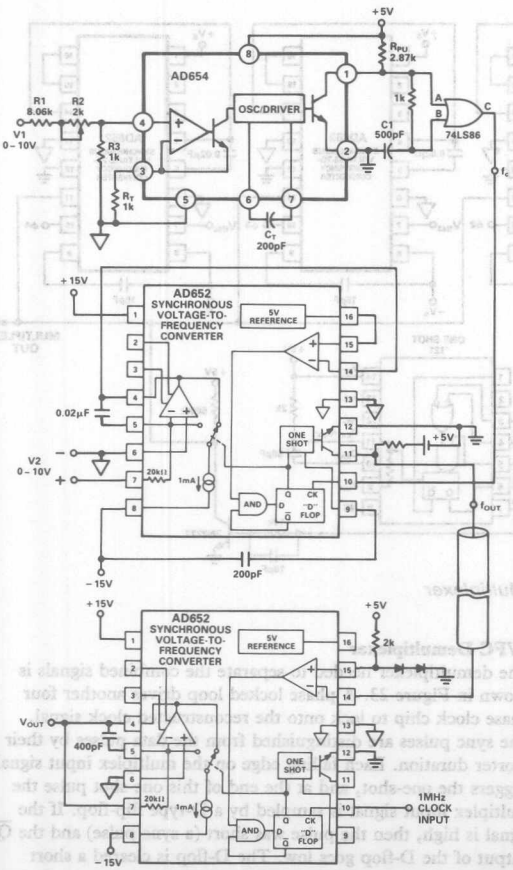

Figure 18. Frequency Output Multiplier

This 1MHz full-scale frequency is then used as the clock input to the AD652 SVFC. Since the AD652 full-scale output frequency is one-half the clock frequency, the 1MHz FS clock frequency establishes a 500kHz maximum output frequency for the AD652 when its input voltage (V_2) is +10V. The user thus has an output frequency range from 0-500kHz which is proportional to the product of V_1 and V_2.

This can be shown in equation form, where f_C is the AD654 output frequency and f_{OUT} is the AD652 output frequency:

$$f_C = V_1 \frac{1MHz}{10V}$$

$$f_{OUT} = V_2 \left(\frac{f_C/2}{10V}\right)$$

$$f_{OUT} = V_1 V_2 \left(\frac{1MHz}{2(10V)\,(10V)}\right)$$

$$f_{OUT} = V_1 \cdot V_2 \cdot 5kHz/V^2$$

The scope photo in Figure 19 shows V_1 and V_2 (top two traces) and the output of the F-V (bottom trace).

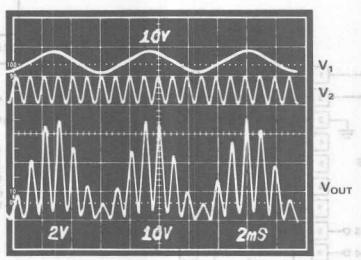

Figure 19. Multiplier Waveforms

SINGLE-LINE MULTIPLEXED DATA TRANSMISSION

It is often necessary to measure several different signals and relay the information to some remote location using a minimum amount of cable. Multiple AD652 SVFC devices may be used with a multiphase clock to combine these measurements for serial transmission and demultiplexing. Figure 20 shows a block diagram of a single-line multiplexed data transmission system with high noise immunity. Figures 21, 22 and 23 show the SVFC multiplexer, a representative means of data transmission, and an SVFC demultiplexer respectively.

Multiplexer

Figure 21 shows the SVFC multiplexer. The clock inputs for the several SVFC channels are generated by a TIM9904A four phase clock driver, and the frequency outputs are combined by strapping all the frequency output pins together (a "wire or" connection). The one-shot in the AD652 sets the pulse width of the frequency output pulses to be slightly shorter than one quarter of the clock period. Synchronization is achieved by applying one of the four available phases to a fixed TTL one-shot ('121) and combining the output with an external transistor. The width of this sync pulse is shorter than the width of the frequency output pulses to facilitate decoding the signal. The RC lag network on the input of the one-shot provides a slight delay between the rising edge of the clock and the sync pulse in

[1]"Noise Reduction Techniques in Electronic Systems," by H.W. Ott, (John Wiley, 1976).

edge of the clock and the output pulse.

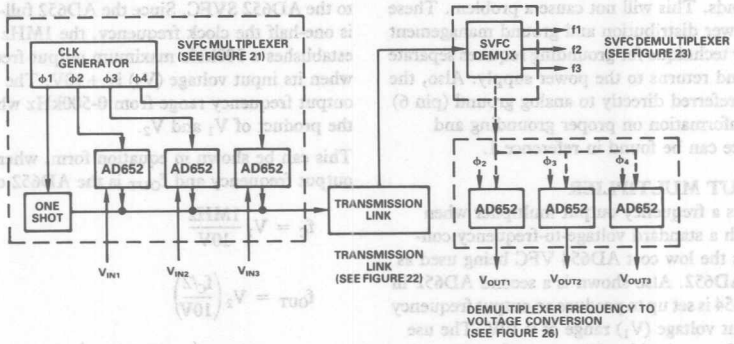

Figure 20. Single Line Multiplexed Data Transmission Block Diagram

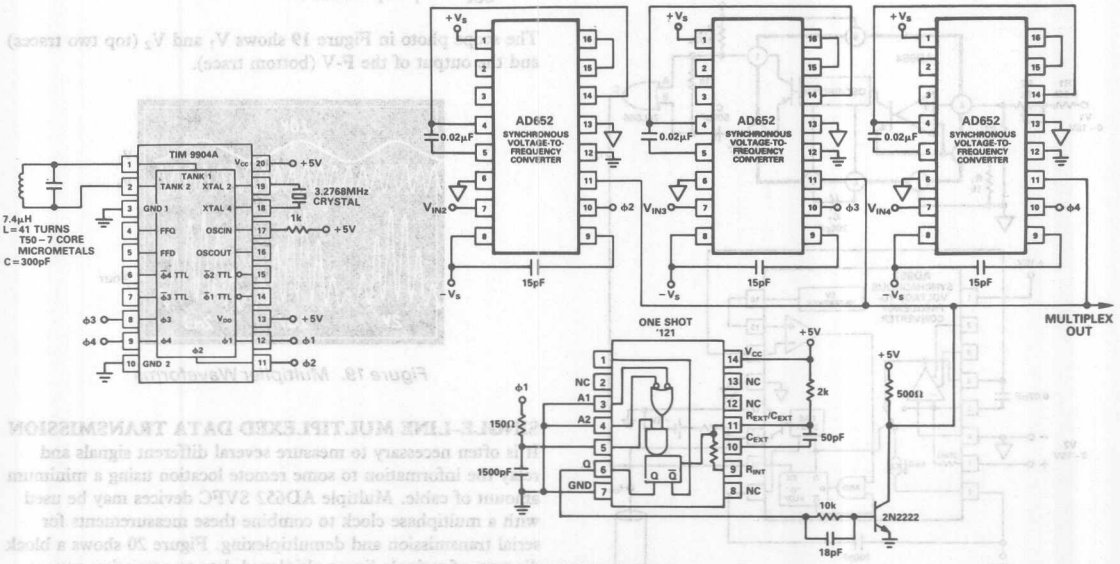

Figure 21. SVFC Multiplexer

Transmitter

The multiplex signal can be transmitted in any manner suitable to the task at hand. A pulse transformer or an opto-isolator can provide galvanic isolation; extremely high voltage isolation or transmission through severe RF environments can be accomplished with a fiber-optic link; telemetry can be accomplished with a radio link. The circuit shown in Figure 22 uses an EIA RS-422 standard for digital data transmission over a balanced line. Figure 24 shows the waveforms of the four clock phases and the multiplex output signal. Note that the sync pulse is present every clock cycle, but the data pulses are no more frequent than every other clock cycle since the maximum output frequency from the SVFC is half the clock frequency. The clock frequency used in this circuit is 819.2 kHz and will provide more than 16 bits of resolution if 100 millisecond gate time is allowed for counting pulses of the decoded output frequencies.

SVFC Demultiplexer

The demultiplexer needed to separate the combined signals is shown in Figure 23. A phase locked loop drives another four phase clock chip to lock onto the reconstructed clock signal. The sync pulses are distinguished from the data pulses by their shorter duration. Each falling edge on the multiplex input signal triggers the one-shot, and at the end of this one-shot pulse the multiplex input signal is sampled by a D-type flip-flop. If the signal is high, then the pulse was short (a sync pulse) and the $\overline{Q}$ output of the D-flop goes low. The D-flop is cleared a short time (two gate delays) later, and the clock is reconstructed as a stream of short, low-going pulses. If the Multiplex input is a data pulse, then when the D-flop samples at the end of the one-shot period, the signal will still be low and no pulse will appear at the reconstructed clock output. These waveforms are shown in Figure 25.

If it is desired to recover the individual frequency signals, then the multiplex input is sampled with a D-flop at the appropriate time as determined by the rising edge of the various phases generated by the clock chip. These frequency signals can be counted as a ratio relative to the reconstructed clock, so it is not even necessary for the transmitter to be crystal controlled as shown here.

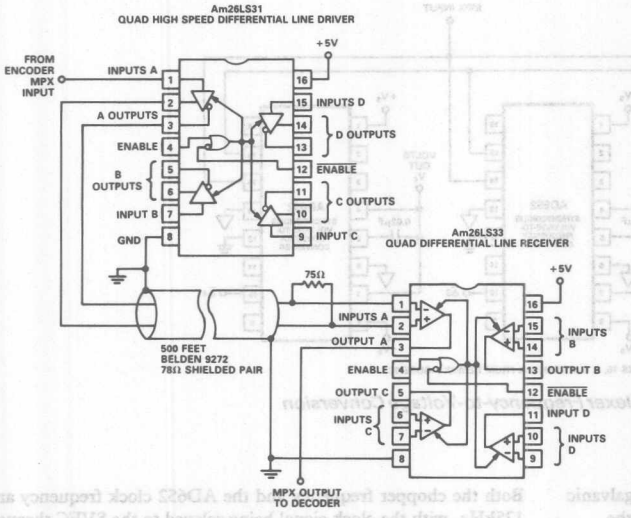

Figure 22. RS-422 Standard Data Transmission

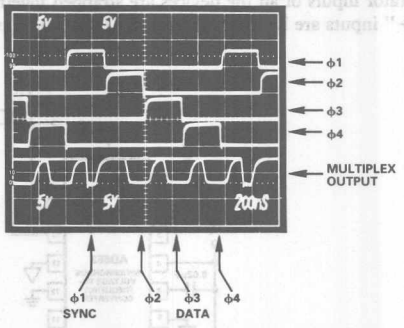

Figure 24. Multiplexer Waveforms

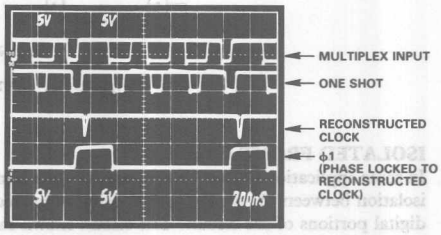

Figure 25. Demultiplexer Waveforms

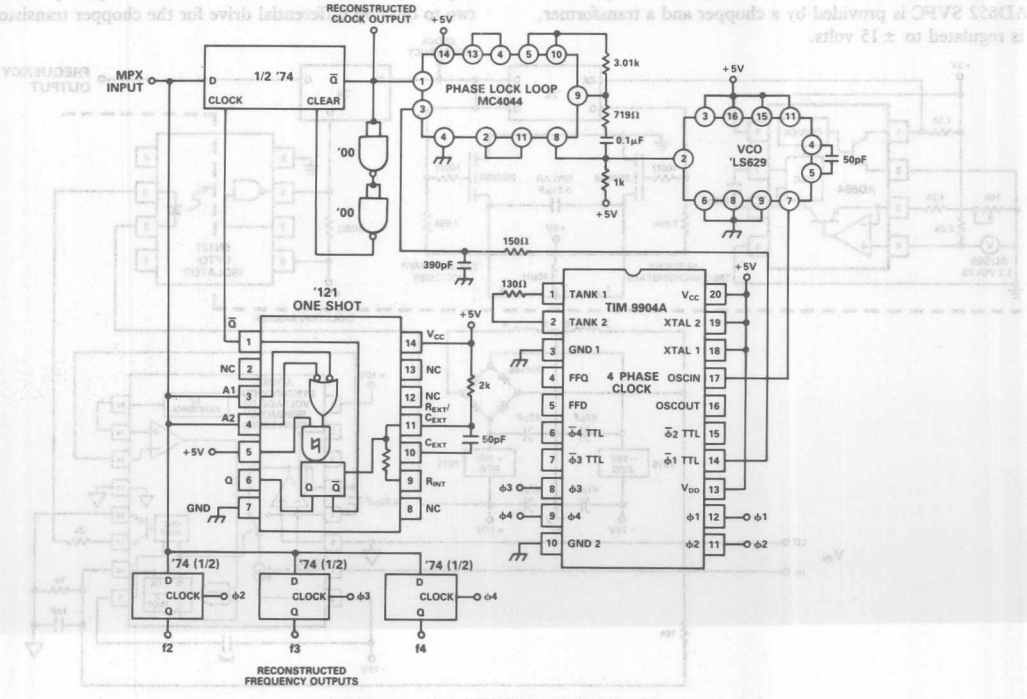

Figure 23. SVFC Demultiplexers

Analog Signal Reconstruction

If it is desired to reconstruct the analog voltages from the multiplex signal, then three more AD652 SVFC devices are used as frequency-to-voltage converters, as shown in Figure 26. The comparator inputs of all the devices are strapped together, and the "+" inputs are held at a 1.2 volt TTL threshold, while the "–" inputs are driven by the multiplex input. The three clock inputs are driven by the $\overline{\phi}$ outputs of the clock chip. Remember that data at the comparator input of the SVFC is loaded on the falling edge of the clock signal and shifted out on the next rising edge. Note that the frequency signals for each data channel are available at the frequency output pin of each FVC.

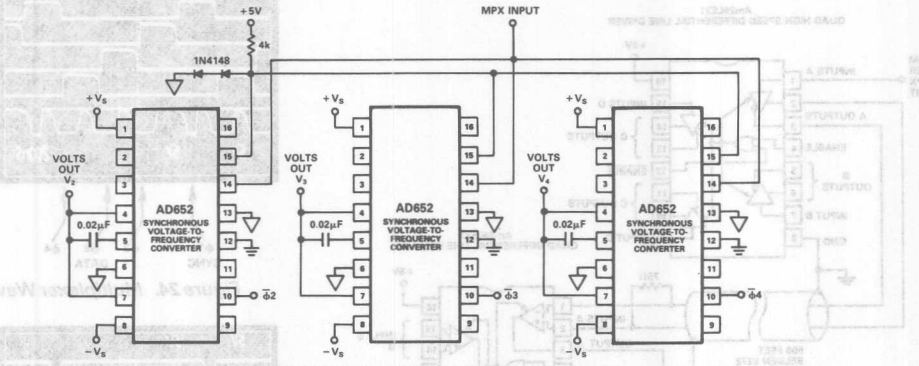

Figure 26. Demultiplexer Frequency-to-Voltage Conversion

ISOLATED FRONT END

In some applications it may be necessary to have complete galvanic isolation between the analog signals being measured and the digital portions of the circuit. The circuit shown in Figure 27 runs off a single 5 volt power supply and provides a self-contained, completely isolated analog measurement system. The power for the AD652 SVFC is provided by a chopper and a transformer, and is regulated to ±15 volts. Both the chopper frequency and the AD652 clock frequency are 125kHz, with the clock signal being relayed to the SVFC through the transformer. The frequency output signal is relayed through an opto-isolator and latched into a D-flop. The chopper frequency is generated from an AD654 VFC and is frequency divided by two to develop differential drive for the chopper transistors, and

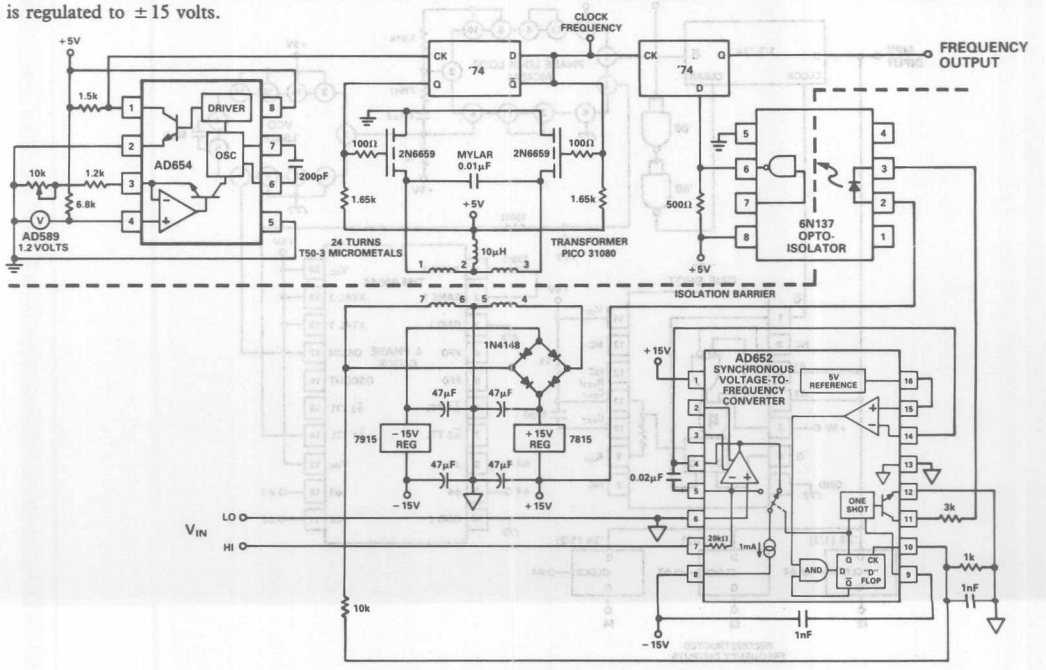

Figure 27. Isolated Synchronous VFC

to ensure an accurate 50 percent duty cycle. The pull-up resistors on the D-flop outputs provide a well defined high level voltage to the choppers to equalize the drive in each direction. The 10μH inductor in the +5V lead of the transformer primary is necessary to equalize any residual imbalance in the drive on each half-cycle and thus prevent saturation of the core. The capacitor across the primary resonates the system so that under light loading conditions on the secondary the wave shape will be sinusoidal and the clock frequency will be relayed to the SVFC. To adjust the chopper frequency, disconnect any load on the secondary and tune the AD654 for a minimum in the supply current drawn from the 5 volt supply.

A-TO-D CONVERSION

In performing an A-to-D conversion, the output pulses of a VFC are counted for a fixed gate interval. To achieve maximum performance with the AD652, the fixed gate interval should be generated using a multiple of the SVFC clock input. Counting in this manner will eliminate any errors due to the clock (whether it be jitter, drift with time or temperature, etc.) since it is the ratio of the clock and output frequencies that is being measured.

The resolution of the A-to-D conversion measurement is determined by the clock frequency and the gate time. If, for instance, a resolution of 12 bits is desired and the clock frequency is 1MHz (resulting in an AD652 FS frequency of 500kHz) the gate time will be:

$$\left(\frac{\text{FS Freq}}{N}\right)^{-1} = \left(\frac{1}{2}\frac{\text{Clock Freq}}{N}\right)^{-1} = \left(\frac{1\text{MHz}}{2(4096)}\right)^{-1}$$

$$= \frac{8192}{1\times10^{6}}\ \text{sec} = 8.192\text{ms}$$

: Where N is the total number of codes for a given resolution.

Figure 28 shows the AD652 SVFC as an A-to-D converter in block diagram form.

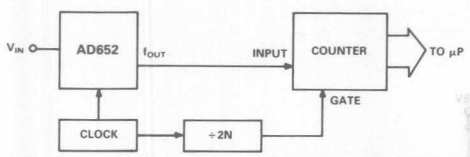

Figure 28. Block Diagram of SVFC A-to-D Converter

To provide the ÷ 2N block a single chip counter such as the 4020B can be used. The 4020B is a 14-stage binary ripple counter which has a clock and master reset for inputs, and buffered outputs from the first stage and the last eleven stages. The output of the first stage is $f_{CLOCK} \div 2^1 = f_{CLOCK}/2$, while the output of the last stage is $f_{CLOCK} \div 2^{14} = f_{CLOCK}/16384$. Hence using this single chip counter as the ÷ 2N block, 13-bit resolution can be achieved. Higher resolution can be achieved by cascading D-type flip-flops or another 4020B with the counter.

Table I shows the relationship between clock frequency and gate time for various degrees of resolution. Note that if the variables are chosen such that the gate times are multiples of 50, 60 or 400Hz, normal-mode rejection (NMR) of those line frequencies will occur.

DELTA MODULATOR

The circuit of Figure 29 shows the AD652 configured as a delta modulator. A reference voltage is applied to the input of the integrator (pin 7), which sets the steady state output frequency at one-half of the AD652 full-scale frequency (1/4 of the clock frequency). As a 0 to 10V input signal is applied to the comparator (pin 15), the output of the integrator attempts to track this signal. For an input in an idling condition (dc) the output frequency will be one-half full scale. For positive going signals the output frequency will be between one-half full scale and full scale, and for negative going signals the output frequency will be between zero and one-half full scale. The output frequency will correspond to the slope of the comparator input signal.

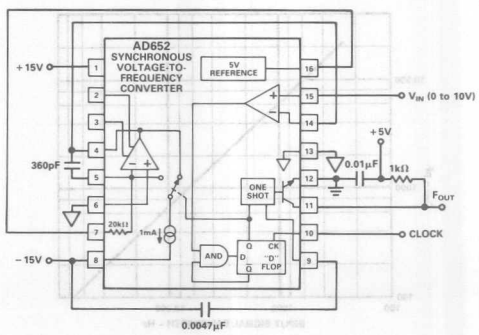

Figure 29. Delta Modulator

Since the output frequency corresponds to the slope of the input signal, the delta modulator acts as a differentiator. A delta modulator is thus a direct way of finding the derivative of a signal. This is useful in systems where, for example, a signal corresponding to velocity exists and it is desired to determine acceleration.

Figure 30 is a scope photo showing a 20kHz, 0 to 10V sine wave used as the input to the comparator and its ramp-wise approximation at the integrator output. The clock frequency used as 2MHz and the integrating capacitor was 360pF. Figure 31 shows the same input signal and its ramp-wise approximation, along with the output frequency corresponding to the derivative of the input signal. In this case the clock frequency was 850kHz.

The choice of an integrating capacitor is primarily dictated by the input signal bandwidth. Figure 32 shows this relationship. It should be noted that as the value of C_{INT} is lowered, the ramp size of the integrator approximation becomes larger. This can be compensated for by increasing the clock frequency. The

in Figures 30 and 31.

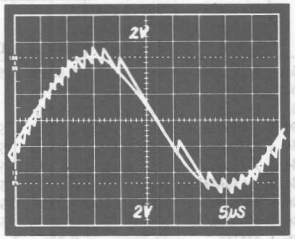

Figure 30. Delta Modulator Input Signal and Ramp-Wise Approximation

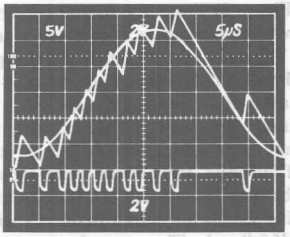

Figure 31. Delta Modulator Input Signal, Ramp-Wise Approximation and Output Frequency

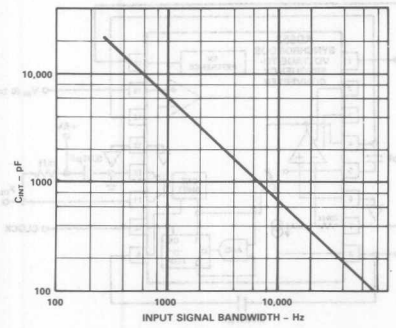

Figure 32. Maximum Integrating Cap Value vs. Input Signal Bandwidth

The circuit of Figure 33 illustrates a simple interface between the AD652 and a bridge-type transducer. The AD652 is an ideal choice because its buffered 5 volt reference can be used as the bridge excitation thereby ratiometrically eliminating the gain drift related errors. This reference will provide a minimum of 10mA of external current, which is adequate for bridge resistance of 600Ω and above. If, for example, the bridge resistance is 120Ω or 350Ω, an external pull-up resistor (R_{PU}) is required and can be calculated using the formula:

$$R_{PU}\,(\max) = \frac{+V_S - 5V}{\frac{5V}{R_{BRIDGE}} - 10mA}$$

An instrumentation amplifier is used to condition the bridge signal before presenting it to the SVFC. The AD625, with its high CMRR, minimizes common-mode errors and also can be set to arbitrary gains between 1 and 10,000 via three resistors, simplifying the scaling for the AD652's calibrated 10 volt input range. These resistors should be selected such that the following equation holds:

$$10V = V_{BRIDGE}\left(\frac{2R_F}{R_G} + 1\right)$$

where $10k\Omega \le R_F \le 20k\Omega$, and V_{BRIDGE} is the maximum output voltage of the bridge.

The bridge output may be unipolar, as is the case for most pressure transducers, or it may be bipolar as in some strain measurements. If the signal is unipolar, the reference input of the AD625 (pin 7) is simply grounded. If the bridge has a bipolar output, however, the AD652 reference can be tied to pin 7, thereby converting a ±5 volt signal (after gain) into a 0 to +10 volt input for the SVFC.

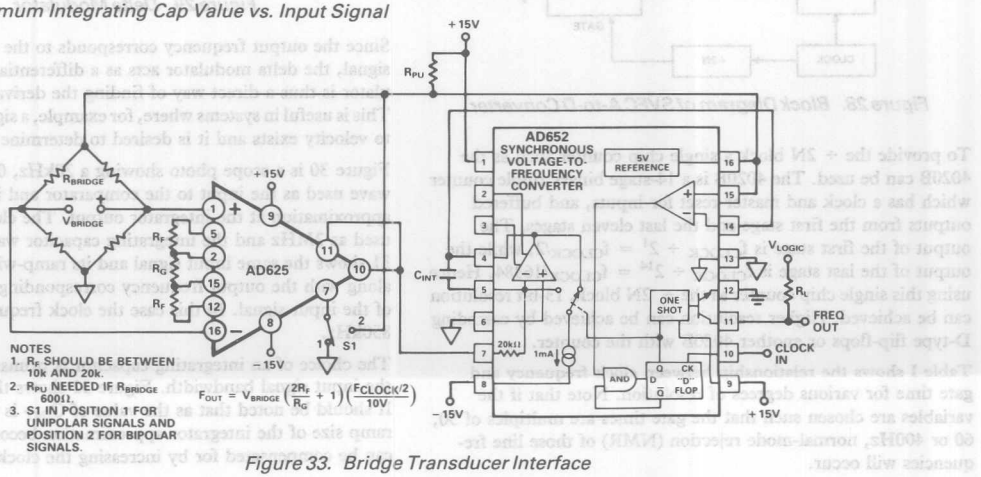

Figure 33. Bridge Transducer Interface

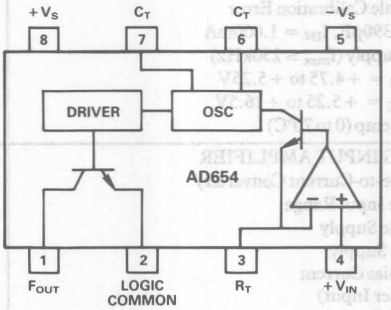

Low Cost Monolithic Voltage-to-Frequency Converter

AD654

FEATURES

- **Low Cost**
- **Single or Dual Supply, 5 to 36 Volts, ±5V to ±18V**
- **Full Scale Frequency Up to 500kHz**
- **Minimum Number of External Components Needed**
- **Versatile Input Amplifier**
  - **Positive or Negative Voltage Modes**
  - **Negative Current Mode**
  - **High Input Impedance, Low Drift**
- **Low Power: 2.0mA Quiescent Current**
- **Low Offset: 1mV**

FUNCTIONAL BLOCK DIAGRAM

PRODUCT DESCRIPTION

The AD654 is a monolithic V/F converter consisting of an input amplifier, a precision oscillator system, and a high current output stage. A single RC network is all that is required to set up any full scale (F.S.) frequency up to 500kHz and any F.S. input voltage up to ±30V. Linearity error is only 0.03% for a 250kHz F.S., and operation is guaranteed over an 80dB dynamic range. The overall temperature coefficient (excluding the effects of external components) is typically ±50ppm/°C. The AD654 operates from a single supply of 5 to 36V and consumes only 2.0mA quiescent current.

The low drift (4μV/°C typ) input amplifier allows operation directly from small signals such as thermocouples or strain gauges while offering a high (250MΩ) input resistance. Unlike most V/F converters, the AD654 provides a square-wave output, and can drive up to 12 TTL loads, opto-couplers, long cables, or similar loads.

PRODUCT HIGHLIGHTS

1. Packaged in both an 8-pin mini-DIP and an 8-pin SOIC package, the AD654 is a complete V/F converter requiring only an RC timing network to set the desired full scale frequency and a selectable pull-up resistor for the open-collector output stage. Any full scale input voltage range from 100mV to 10 volts (or greater, depending on $+V_S$) can be accommodated by proper selection of the timing resistor. The full scale frequency is then set by the timing capacitor from the simple relationship, f = V/10RC.
2. A minimum number of low cost external components are necessary. A single RC network is all that is required to set up any full scale frequency up to 500kHz and any full scale input voltage up to ±30V.
3. Plastic packaging allows low cost implementation of the standard VFC applications: A/D conversion, isolated signal transmission, F/V conversion, phase-locked loops, and tuning switched-capacitor filters.
4. Power supply requirements are minimal; only 2.0mA of quiescent current is drawn from the single positive supply from 4.5 to 36 volts. In this mode, positive inputs can vary from 0 volts (ground) to $(+V_S - 4)$ volts. Negative inputs can easily be connected for below ground operation.
5. The versatile open-collector output stage can sink more than 10mA with a saturation voltage less than 0.4 volts. The Logic Common terminal can be connected to any level between ground (or $-V_S$) and 4 volts below $+V_S$. This allows easy direct interface to any logic family with either positive or negative logic levels.

AD654 —SPECIFICATIONS

CIRCUIT OPERATION

The AD654's block diagram appears in Figure 1. A versatile operational amplifier serves as the input stage; its purpose is to convert and scale the input voltage signal to a drive current in the NPN follower. Optimum performance is achieved when, at the full scale input voltage, a 1mA drive current is delivered to the current-to-frequency converter (an astable multivibrator). The drive current provides both the bias levels and the charging current to the externally connected timing capacitor. This "adaptive" bias scheme allows the oscillator to provide low nonlinearity over the entire current input range of 100nA to 2mA. The square wave oscillator output goes to the output driver which provides a floating base drive to the NPN power transistor. This floating drive allows the logic interface to be referenced to a level other than $-V_S$.

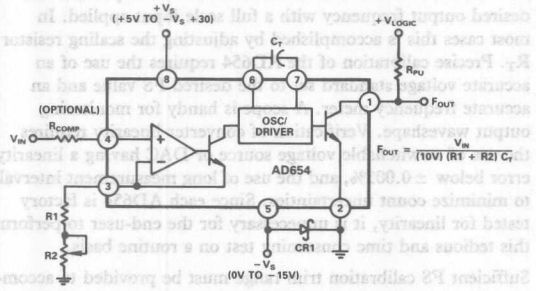

Figure 1. Standard V-F Connection for Positive Input Voltages

V/F CONNECTION FOR POSITIVE INPUT VOLTAGES

In the connection scheme of Figure 1, the input amplifier presents a very high (250MΩ) impedance to the input voltage, which is converted into the proper drive current by the scaling resistors at pin 3. Resistors R1 and R2 are selected to provide a 1mA full scale current with enough trim range to accommodate the AD654's 10% FS error and the components' tolerances. Full scale currents other than 1mA can be chosen, but linearity will be reduced; 2mA is the maximum allowable drive. The AD654's positive input voltage range spans from $-V_S$ (ground in single supply operation) to four volts below the positive supply. Power supply rejection degrades as the input exceeds $(+V_S - 3.75V)$ and at $(+V_S - 3.5V)$ the output frequency goes to zero.

As indicated by the scaling relationship in Figure 1, a 0.01μF timing capacitor will give a 10kHz full scale frequency, and 0.001μF will give 100kHz with a 1mA drive current. Good V/F linearity requires the use of a capacitor with low dielectric absorption (DA), while the most stable operation over temperature calls for a component having a small tempco. Polystyrene, polypropylene, or Teflon* capacitors are preferred for tempco and dielectric absorption; other types will degrade linearity. The capacitor should be wired very close to the AD654. In Figure 1, Schottky diode CR1 (MBD101) prevents logic common from dropping more than 500mV below $-V_S$. This diode is not required if $-V_S$ is equal to logic common.

V/F CONNECTIONS FOR NEGATIVE INPUT VOLTAGE OR CURRENT

The AD654 can accommodate a wide range of negative input voltages with proper selection of the scaling resistor, as indicated in Figure 2. This connection, unlike the buffered positive connection, is not high impedance because the signal source must supply the 1mA F.S. drive current. However, large negative voltages beyond the supply can be handled easily by modifying the scaling resistors appropriately. If the input is a true current source, R1 and R2 are not used. Again, diode CR1 prevents latch-up by insuring Logic Common does not drop more than 500mV below $-V_S$. The clamp diode (MBD101) protects the AD654 input from "below $-V_S$" inputs.

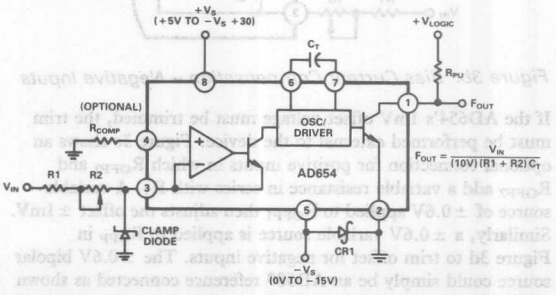

Figure 2. V-F Connections for Negative Input Voltages or Current

OFFSET CALIBRATION

In theory, two adjustments calibrate a V/F: scale and offset. In practice, most applications find the AD654's 1mV max voltage offset sufficiently low to forgo offset calibration. However, the input amplifier's 30nA (typ) bias currents will generate an offset due to the difference in DC source resistance between the input terminals. This offset can be substantial for large values of $R_T = R_1 + R_2$ and will vary as the bias currents drift over temperature. Therefore, to maintain the AD654's low offset, the application may require balancing the DC source resistances at the inputs (pins 3 and 4).

For positive inputs, this is accomplished by adding a compensation resistor nominally equal to R_T in series with the input as shown in Figure 3a. This limits the offset to the product of the 30nA bias current and the mismatch between the source resistance R_T and R_{COMP}. A second, smaller offset arises from the inputs' 5nA offset current flowing through the source resistance R_T or R_{COMP}. For negative input voltage and current connections, the compensation resistor is added at pin 4 as shown in Figure 3b in lieu of grounding the pin directly. For both positive and negative inputs, the use of R_{COMP} may lead to noise coupling at pin 4 and should therefore be bypassed for lowest noise operation.

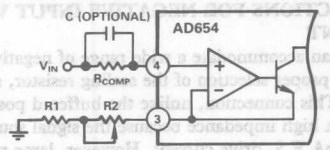

Figure 3a. Bias Current Compensation – Positive Inputs

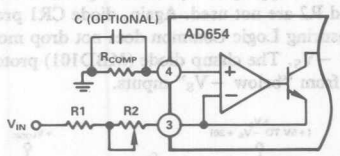

Figure 3b. Bias Current Compensation – Negative Inputs

If the AD654's 1mV offset voltage must be trimmed, the trim must be performed external to the device. Figure 3c shows an optional connection for positive inputs in which R_{OFF1} and R_{OFF2} add a variable resistance in series with R_T. A variable source of ±0.6V applied to R_{OFF1} then adjusts the offset ±1mV. Similarly, a ±0.6V variable source is applied to R_{OFF} in Figure 3d to trim offset for negative inputs. The ±0.6V bipolar source could simply be an AD589 reference connected as shown in Figure 3e.

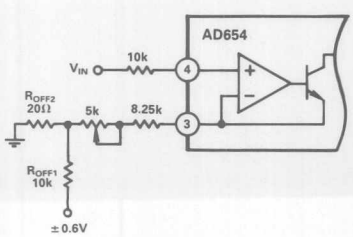

Figure 3c. Offset Trim Positive Input (10V FS)

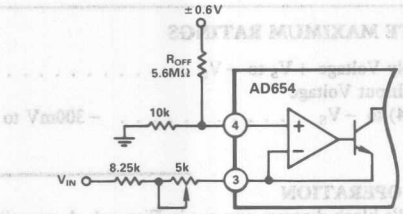

Figure 3d. Offset Trim Negative Input (–10V FS)

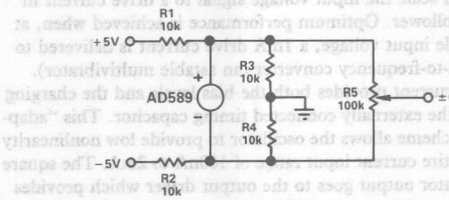

Figure 3e. Offset Trim Bias Network

FULL SCALE CALIBRATION

Full scale trim is the calibration of the circuit to produce the desired output frequency with a full scale input applied. In most cases this is accomplished by adjusting the scaling resistor R_T. Precise calibration of the AD654 requires the use of an accurate voltage standard set to the desired FS value and an accurate frequency meter. A scope is handy for monitoring output waveshape. Verification of converter linearity requires the use of a switchable voltage source or DAC having a linearity error below ±0.005%, and the use of long measurement intervals to minimize count uncertainties. Since each AD654 is factory tested for linearity, it is unnecessary for the end-user to perform this tedious and time consuming test on a routine basis.

Sufficient FS calibration trim range must be provided to accommodate the worst-case sum of all major scaling errors. This includes the AD654's 10% full scale error, the tolerance of the fixed scaling resistor, and the tolerance of the timing capacitor. Therefore, with a resistor tolerance of 1% and a capacitor tolerance of 5%, the fixed part of the scaling resistor should be a maximum of 84% of nominal, with the variable portion selected to allow 116% of the nominal.

If the input is in the form of a negative current source, the scaling resistor is no longer required, eliminating the capability of trimming FS frequency in this fashion. Since it is usually not practical to smoothly vary the capacitance for trimming purposes, an alternative scheme such as the one shown in Figure 4 is needed. Designed for a FS of 1mA, this circuit divides the input into two current paths. One path is through the 100Ω

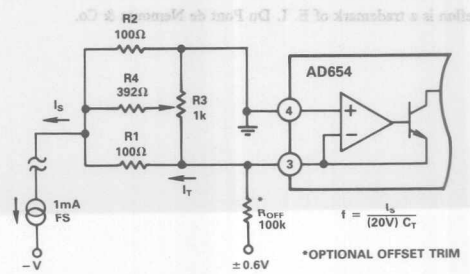

Figure 4. Current Source FS Trim

resistor R1, and flowing into pin 3; it constitutes the signal current I_T to be converted. The second path, through another 100Ω resistor R2, carries the same nominal current. Two equal valued resistors offer the best overall stability, and should be either 1% discrete film units, or a pair from a common array.

Since the 1mA FS input current is divided into two 500μA legs (one to ground and one to pin 3), the total input signal current (I_S) is divided by a factor of two in this network. To achieve the same conversion scale factor, C_T must be reduced by a factor of two. This results in a transfer unique to this hookup:

$$f = \frac{I_S}{(20V)\ C_T}$$

For calibration purposes, resistors R3 and R4 are added to the network, allowing a ±15% trim of scale factor with the values shown. By varying R4's value the trim range can be modified to accommodate wider tolerance components or perhaps the calibration tolerance on a current output transducer such as the AD592 temperature sensor. Although the values of R1 – R4 shown are valid for 1mA FS signals only, they can be scaled upward proportionately for lower FS currents. For instance, they should be increased by a factor of ten for a FS current of 100μA.

In addition to the offsets generated by the input amplifier's bias and offset currents, an offset voltage induced parasitic current arises from the current fork input network. These effects are minimized by using the bias current compensation resistor R_{OFF} and offset trim scheme shown in Figure 3e.

Although device warmup drifts are small, it is good practice to allow the devices operating environment to stabilize before trim, and insure the supply, source and load are appropriate. If provision is made to trim offset, begin by setting the input to 1/10,000 of full scale. Adjust the offset pot until the output is 1/10,000 of full scale (for example, 25Hz for a FS of 250kHz). This is most easily accomplished using a frequency meter connected to the output. The FS input should then be applied and the gain pot should be adjusted until the desired FS frequency is indicated.

INPUT PROTECTION

The AD654 was designed to be used with a minimum of additional hardware. However, the successful application of a precision IC involves a good understanding of possible pitfalls and the use of suitable precautions. Thus $+V_{IN}$ and R_T pins should not be driven more than 300mV below $-V_S$. Likewise, Logic Common should not drop more than 500mV below $-V_S$. This would cause internal junctions to conduct, possibly damaging the IC. In addition to the diode shown in Figures 1 and 2 protecting Logic Common, a second Schottky diode (MBD101) can protect the AD654's inputs from "below $-V_S$" inputs as shown in Figure 5. It is also desirable not to drive $+V_{IN}$ and R_T above $+V_S$. In operation, the converter will exhibit a zero output for inputs above ($+V_S$ – 3.5V). Also, control currents above 2mA will increase nonlinearity.

The AD654's 80dB dynamic range guarantees operation from a control current of 1mA (nominal FS) down to 100nA (equivalent to 1mV to 10V FS). Below 100nA improper operation of the oscillator may result, causing a false indication of input amplitude. In many cases this might be due to short-lived noise spikes which become added to input. For example, when scaled to accept an FS input of 1V, the −80dB level is only 100μV, so when the mean input is only 60dB below FS (1mV), noise spikes

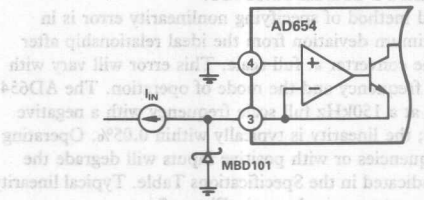

Figure 5. Input Protection

of 0.9mV are sufficient to cause momentary malfunction.

This effect can be minimized by using a simple low-pass filter ahead of the converter or a guard ring around the R_T pin. The filter can be assembled using the bias current compensation resistor discussed in the previous section. For an FS of 10kHz, a single-pole filter with a time constant of 100ms will be suitable, but the optimum configuration will depend on the application and the type of signal processing. Noise spikes are only likely to be a cause of error when the input current remains near its minimum value for long periods of time; above 100nA full integration of additive input noise occurs. Like the inputs, the capacitor terminals are sensitive to interference from other signals. The timing capacitor should be located as close as possible to the AD654 to minimize signal pickup in the leads. In some cases, guard rings or shielding may be required.

DECOUPLING

It is good engineering practice to use bypass capacitors on the supply-voltage pins and to insert small-valued resistors (10 to 100Ω) in the supply lines to provide a measure of decoupling between the various circuits in the system. Ceramic capacitors of 0.1μF to 1.0μF should be applied between the supply-voltage pins and analog signal ground for proper bypassing on the AD654. A proper ground scheme appears in Figure 6.

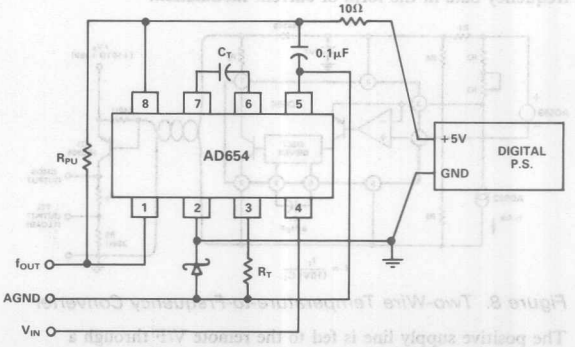

Figure 6. Proper Ground Scheme

OUTPUT INTERFACING CONSIDERATIONS

The output stage's design allows easy interfacing to all digital logic families. The output NPN transistor's emitter and collector are both uncommitted. The emitter can be tied to any voltage between $-V_S$ and 4 volts below $+V_S$, and the open collector can be pulled up to a voltage 36 volts above the emitter regardless of $+V_S$. The high power output stage can sink over 10mA at a maximum saturation voltage of 0.4V. The stage limits the output current at 25mA and can handle this limit indefinitely without damaging the device.

calibrating the converter at full scale. This error will vary with the full scale frequency and the mode of operation. The AD654 operates best at a 150kHz full scale frequency with a negative voltage input; the linearity is typically within 0.05%. Operating at higher frequencies or with positive inputs will degrade the linearity as indicated in the Specifications Table. Typical linearity at various temperatures is shown in Figure 7.

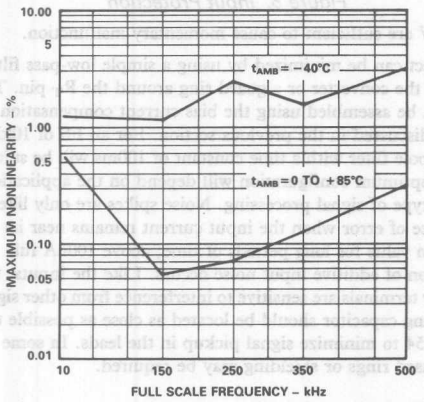

Figure 7. Typical Nonlinearities at Different Full-Scale Frequencies

TWO-WIRE TEMPERATURE-TO-FREQUENCY CONVERSION

Figure 8 shows the AD654 in a two-wire temperature-to-frequency conversion scheme. The twisted pair transmission line serves the dual purpose of supplying power to the device and also carrying frequency data in the form of current modulation.

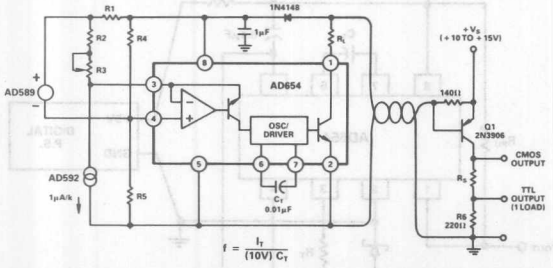

Figure 8. Two-Wire Temperature-to-Frequency Converter

The positive supply line is fed to the remote V/F through a 140Ω resistor. This resistor is selected such that the quiescent current of the AD654 will cause less than one V_{BE} to be dropped. As the V/F oscillates, additional switched current is drawn through R_L when pin 1 goes low. The peak level of this additional current causes Q1 to saturate, and thus regenerates the AD654's output square wave at the collector. The supply voltage to the AD654 then consists of a DC level, less the resistive line drop, plus a one V_{BE} p-p square wave at the output frequency of the AD654. This ripple is reduced by the diode/capacitor combination.

To set up the receiver circuit for a given voltage, the R_S and R_L resistances are selected as shown in Table I. CMOS logic stages

$+V_S$	R_S	R_L
10V	270Ω	1.8k
15V	680Ω	2.7k

Table I.

	$(+V_S)$	R1	R2	R3	R4	R5	
K	10V	–	–	–	100k	127k	F = 10Hz/K
	15V	–	–	–	100k	127k	
°C	10V	6.49k	4.02k	1k	95.3k	22.6k	F = 10Hz/°C
	15V	12.7k	4.02k	1k	78.7k	36.5k	
°F	10V	6.49k	4.42k	1k	154k	22.6k	F = 5.55Hz/°F
	15V	12.7k	4.42k	1k	105k	36.5k	

Table II.

At the V/F end, the AD592C temperature transducer is interfaced with the AD654 in such a manner that the AD654 output frequency is proportional to temperature. The output frequency can be scaled and offset from K to °C or °F using the resistor values shown in Table II. Since temperature is the parameter of interest, an NPO ceramic capacitor is used as the timing capacitor for low V/F TC.

When scaling per K, resistors R1 – R3 and the AD589 voltage reference are not used. The AD592 produces a 1μA/K current output which drives pin 3 of the AD654. With the timing capacitor of 0.01μF this produces an output frequency scaled to 10Hz/K. When scaling per °C and °F, the AD589 and resistors R1 – R3 offset the drive current at pin 3 by 273.2μA for scaling per °C and 255.42μA for scaling per °F. This will result in frequencies scaled at 10Hz/°C and 5.55Hz/°F, respectively.

OPTOISOLATOR COUPLING

A popular method of isolated signal coupling is via optoelectronic isolators, or optocouplers. In this type of device, the signal is coupled from an input LED to an output photo-transistor, with light as the connecting medium. This technique allows DC to be transmitted, is extremely useful in overcoming ground loop problems between equipment, and is applicable over a wide range of speeds and power.

Figure 9 shows a general purpose isolated V/F circuit using a low cost 4N37 optoisolator. A +5V power supply is assumed for both the isolated (+5V isolated) and local (+5V local) supplies. The input LED of the isolator is driven from the collector output of the AD654, with a 9mA current level established by R1 for high speed, as well as for a 100% current transfer ratio.

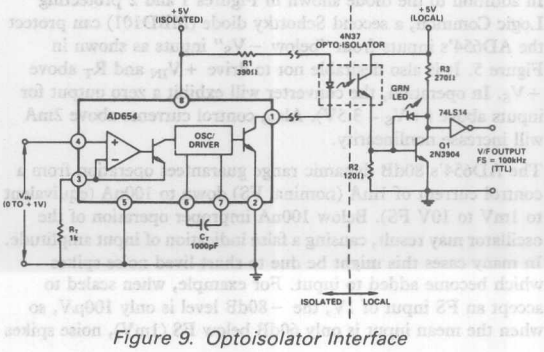

Figure 9. Optoisolator Interface

At the receiver side, the output transistor is operated in the photo-transistor mode; that is with the base lead (pin 6) open. This allows the highest possible output current. For reasonable speed in this mode, it is imperative that the load impedance be as low as possible. This is provided by the single transistor stage current-to-voltage converter, which has a dynamic load impedance of less than 10 ohms and interfaces with TTL at the output.

USING A STAND-ALONE FREQUENCY COUNTER/LED DISPLAY DRIVER FOR VOLTMETER APPLICATIONS

Figure 10 shows the AD654 used with a stand-alone frequency counter/LED display driver. With C_T = 1000pF and R_T = 1kΩ the AD654 produces an FS frequency of 100kHz when V_{IN} = +1V. This signal is fed into the ICM7226A, a universal counter system that drives common anode LED's. With the FUNCTION pin tied to D1 through a 10kΩ resistor the ICM7226A counts the frequency of the signal at A_{IN}. This count period is selected by the user and can be 10ms, 100ms, 1s, or 10 seconds, as shown on pin 21. The longer the period selected, the more resolution the count will have. The ICM7226A then displays the frequency on the LED's, driving them directly as shown. Refreshing of the LED's is handled automatically by the ICM7226. The entire circuit operates on a single +5V supply and gives a meter with 3, 4, or 5 digit resolution.

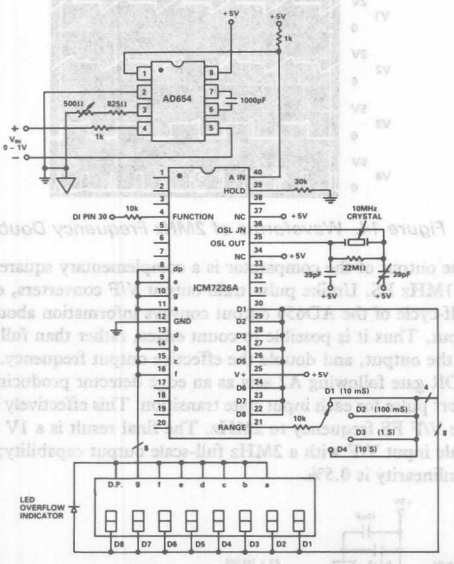

Figure 10. AD654 With Stand-Alone Frequency Counter/LED Display Driver

Longer count periods not only result in the count having more resolution, they also serve as an integration of noisy analog signals. For example, a normal-mode 60Hz sine wave riding on the input of the AD654 will result in the output frequency increasing on the positive half of the sine wave and decreasing on the negative half of the sine wave. This effect is cancelled by selecting a count period equal to an integral number of noise signal periods. A 100ms count period is effective because it not only has an integral number of 60Hz cycles (6), it also has an integral number of 50Hz cycles (5). This is also true of the 1 second and 10 second count period.

AD654-BASED ANALOG-TO-DIGITAL CONVERSION USING A SINGLE CHIP MICROCOMPUTER

The AD654 can serve as an analog-to-digital converter when used with a single component microcomputer that has an interval timer/event counter such as the 8048. Figure 11 shows the AD654, with a full scale input voltage of +1V and a full scale output frequency of 100kHz, connected to the timer/counter input pin T1 of the 8048. Such a system can also operate on a single +5V supply.

The 8748 counter is negative edge triggered; after the STRT CNT instruction is executed subsequent high to low transitions on T1 increment the counter. The maximum rate at which the counter may be incremented is once per three instruction cycles; using a 6MHz crystal, this corresponds to once every 7.5μs, or a maximum frequency of 133kHz. Because the counter overflows every 256 counts (8 bits), the timer interrupt is enabled. Each overflow then causes a jump to a subroutine where a register is incremented. After the STOP TCNT instruction is executed, the number of overflows that have occurred will be the number in this register. The number in this register multiplied by 256 plus the number in the counter will be the total number of negative edges counted during the count period. The count period is handled simply by decrementing a register the number of times necessary to correspond to the desired count time. After the register has been decremented the required number of times, the STOP TCNT instruction is executed.

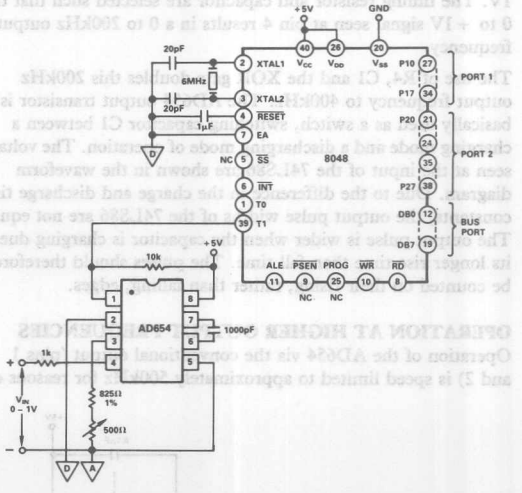

Figure 11. AD654 VFC as an ADC

The total number of negative edges counted during the count period is proportional to the input voltage. For example, if a 1V full-scale input voltage produces a 100kHz signal and the count period is 100ms, then the total count will be 10,000. Scaling from this maximum is then used to determine the input voltage, i.e., a count of 5000 corresponds to an input voltage of 0.5V. As with the ICM7226, longer count times result in counts having more resolution; and they result in the integration of noisy analog signals.

FREQUENCY DOUBLING

Since the AD654's output is a square-wave rather than a pulse train, information about the input signal is carried on both halves of the output waveform. The circuit in Figure 12 converts the output into a pulse train, effectively doubling the output frequency, while preserving the better low frequency linearity of the AD654. This circuit also accommodates an input voltage that is greater than the AD654 supply voltage.

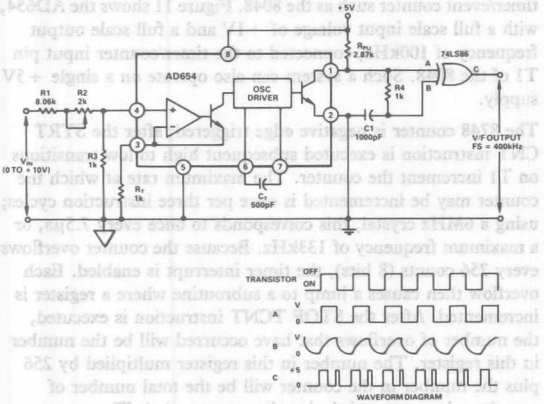

Figure 12. Frequency Doubler

Resistors R1 – R3 are used to scale the 0 to +10V input voltage down to 0 to +1V as seen at pin 4 of the AD654. Recall that V_{IN} must be less than V_{SUPPLY} −4V, or in this case less than 1V. The timing resistor and capacitor are selected such that this 0 to +1V signal seen at pin 4 results in a 0 to 200kHz output frequency.

The use of R4, C1 and the XOR gate doubles this 200kHz output frequency to 400kHz. The AD654 output transistor is basically used as a switch, switching capacitor C1 between a charging mode and a discharging mode of operation. The voltages seen at the input of the 74LS86 are shown in the waveform diagram. Due to the difference in the charge and discharge time constants, the output pulse widths of the 74LS86 are not equal. The output pulse is wider when the capacitor is charging due to its longer rise time than fall time. The pulses should therefore be counted on their rising, rather than falling, edges.

OPERATION AT HIGHER OUTPUT FREQUENCIES

Operation of the AD654 via the conventional output (pins 1 and 2) is speed limited to approximately 500kHz for reasons of TTL logic compatibility. Although the output stage may become speed limited, the multivibrator core itself is able to oscillate to 1MHz or more. The designer may take advantage of this feature in order to operate the device at frequencies in excess of 500kHz.

Figure 13 illustrates this with a circuit offering 2MHz full scale. In this circuit the AD654 is operated at a full scale (FS) of 1mA, with a C_T of 100pF. This achieves a basic device FS frequency of 1MHz across C_T. The P channel JFETs, Q1 and Q2, buffer the differential timing capacitor waveforms to a low impedance level where the push-pull signal is then AC coupled to the high speed comparator A2. Hysteresis is used, via R7, for non-ambiguous switching and to eliminate the oscillations which would otherwise occur at low frequencies.

The net result of this is a very high-speed circuit which does not compromise the AD654 dynamic range. This is a result of the FET buffers typically having only a few pA of bias current. The high end dynamic range is limited, however, by parasitic package and layout capacitances in shunt with C_T, as well as those from each node to AC ground. Minimizing the lead length between A2–6/A2–7 and Q1/Q2 in PC layout will help. A ground plane will also help stability. Figure 14 shows the waveforms V1 – V4 found at the respective points shown in Figure 13.

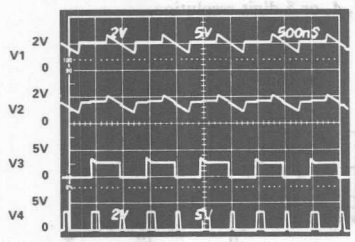

Figure 14. Waveforms of 2MHz Frequency Doubler

The output of the comparator is a complementary square wave at 1MHz FS. Unlike pulse train output V/F converters, each half-cycle of the AD654 output conveys information about the input. Thus it is possible to count edges, rather than full cycles of the output, and double the effective output frequency. The XOR gate following A2 acts as an edge detector producing a short pulse for each input state transition. This effectively doubles the V/F FS frequency to 2MHz. The final result is a 1V full scale input V/F with a 2MHz full-scale output capability; typical nonlinearity is 0.5%.

PRODUCT DESCRIPTION

The industry standard ADVFC32 is a low cost monolithic voltage-to-frequency (V/F) converter or frequency-to-voltage (F/V) converter with good linearity (0.01% max error at 10kHz) and operating frequency up to 0.5MHz. In the V/F configuration, positive or negative input voltages or currents can be converted to a proportional frequency using only a few external components. For F/V conversion, the same components are used with a simple biasing network to accommodate a wide range of input logic levels.

TTL or CMOS compatibility is achieved in the V/F operating mode using an open collector frequency output. The pullup resistor can be connected to voltages up to 30 volts, or to +15V or +5V for conventional CMOS or TTL logic levels. This resistor should be chosen to limit current through the open collector output to 8mA. A larger resistance can be used if driving a high impedance load.

Input offset drift is only 3ppm of full scale per °C, and full scale calibration drift is held to a maximum of 100ppm/°C (ADVFC32BH) due to a low T.C. zener diode.

The ADVFC32 is available in commercial, industrial, and extended temperature grades. The commercial grade is packaged in a 14-pin plastic DIP while the two wider temperature range parts are packaged in hermetically sealed TO-100 cans.

PRODUCT HIGHLIGHTS

1. The ADVFC32 uses a charge balancing circuit technique (see Functional Block Diagram) which is well suited to high accuracy voltage-to-frequency conversion. The full-scale operating frequency is determined by only one precision resistor and capacitor. The tolerance of other support components (including the integration capacitor) is not critical. Inexpensive ±20% resistors and capacitors can be used without affecting linearity or temperature drift.
2. The ADVFC32 is easily configured to satisfy a wide range of system requirements. Input voltage scaling is set by selecting the input resistor which sets the input current to 0.25mA at the maximum input voltage.
3. The same components used for V/F conversion can also be used for F/V conversion by adding a simple logic biasing network and reconfiguring the ADVFC32.
4. The ADVFC32 is intended as a pin-for-pin replacement for VFC32 devices from other manufacturers.
5. The ADVFC32 is available in versions compliant with MIL-STD-883. Refer to the Analog Devices Military Products Databook or current ADVFC32/883B data sheet for detailed specifications.

NOTES

[1]Nonlinearity is defined as deviation from a straight line from zero to full scale, expressed as a percentage of full scale.

[2]See Figure 3.

[3]See Figure 1.

[4]f_{max} expressed in units of MHz.

[5]N = Plastic DIP; H = Hermetic Metal Can. For outline information see Package Information section.

[6]For ADVFC32/883B specifications, refer to Analog Devices Military Products Databook.

Specifications subject to change without notice.

Specifications shown in boldface are tested on all production units at final electrical test. Results from those tests are used to calculate outgoing quality levels. All min and max specifications are guaranteed, although only those shown in boldface are tested on all production units.

[1]For details on grade and package offerings screened in accordance with MIL-STD-883, refer to the Analog Devices Military Products Databook or current ADVFC32/883B data sheet.

3

UNIPOLAR V/F, POSITIVE INPUT VOLTAGE

When operated as a V/F converter, the transformation from voltage to frequency is based on a comparison of input signal magnitude to the 1mA internal current source.

A more complete understanding of the ADVFC32 requires a close examination of the internal circuitry of this part. Consider the operation of the ADVFC32 when connected as shown in Figure 1. At the start of a cycle, a current proportional to the

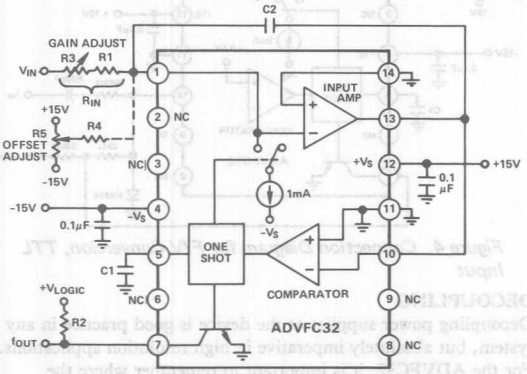

Figure 1. Connection Diagram for V/F Conversion, Positive Input Voltage

input voltage flows through R3 and R1 to charge integration capacitor C2. As charge builds up on C2, the output voltage of the input amplifier decreases. When the amplifier output voltage (pin 13) crosses ground (see Figure 2 at time t_1), the comparator

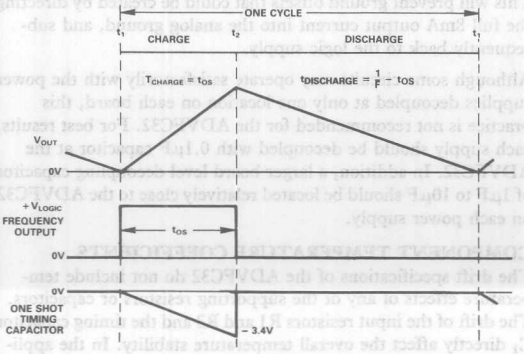

Figure 2. Voltage-to-Frequency Conversion Waveforms

triggers a one shot whose time period is determined by capacitor C1. Specifically, the one shot time period (in nanoseconds) is:

$$t_{OS} \cong (C_1 + 44pF) \times 6.7k\Omega$$

During this period, a current of $(1mA - I_{IN})$ flows out of the integration capacitor. The total amount of charge depleted during one cycle is, therefore $(1mA - I_{IN}) \times t_{OS}$. This charge is replaced during the remainder of the cycle to return the integrator to its original voltage. Since the charge taken out of C2 is equal to the charge that is put on C2 every cycle,

$$(1mA - I_{IN}) \times t_{OS} = I_{IN} \times \left(\frac{1}{F_{OUT}} - t_{OS} \right)$$

or, rearranging terms,

$$F_{OUT} = \frac{I_{IN}}{1mA \times t_{OS}}$$

The complete transfer equation can now be derived by substituting $I_{IN} = V_{IN}/R_{IN}$ and the equation relating C1 and t_{OS}. The final equation describing ADVFC32 operation is:

$$F_{OUT} = \frac{V_{IN}/R_{IN}}{1mA \times (C_1 + 44pF) \times 6.7k\Omega}$$

Components should be selected to optimize performance over the desired input voltage and output frequency range using the equations listed below:

$$C_1 = \frac{3.7 \times 10^7 pF/sec}{F_{OUT\ FS}} - 44pF$$

$$C_2 = \frac{10^{-4}\ Farads/sec}{F_{OUT\ FS}} \quad (1000pF\ minimum)$$

$$R_{IN} = \frac{V_{IN\ FS}}{0.25mA}$$

$$R_2 \geq \frac{+V_{LOGIC}}{8mA}$$

Both R_{IN} and C_1 should have very low temperature coefficients as changes in their values will result in a proportionate change in the V/F transfer function. Other component values and temperature coefficients are not critical.

Table I. Suggested Values for C_1, R_{IN} and C_2

$V_{IN\ FS}$	$F_{OUT\ FS}$	C_1	R_{IN}	C_2
1V	10kHz	3650pF	4.0kΩ	0.01μF
10V	10kHz	3650pF	40kΩ	0.01μF
1V	100kHz	330pF	4.0kΩ	1000pF
10V	100kHz	330pF	40kΩ	1000pF

Input resistance R_{IN} is composed of a fixed resistor (R1) and a variable resistor (R3) to allow for initial gain error compensation. To cover all possible situations, R3 should be 20% of R_{IN}, and R1 should be 90% of R_{IN}. This allows a ±10% gain adjustment to compensate for the ADVFC32 full-scale error and the tolerance of C1.

If more accurate initial offset is required, the circuit of R4 and R5 can be added. R5 can have a value between 10kΩ and 100kΩ, and R4 should be approximately 10MΩ. The amount of current required to trim zero offset will be relatively small, so the temperature coefficients of these resistors are not critical. If large offsets are added using this circuit, temperature drift of both of these resistors is much more important.

BIPOLAR V/F

By adding another resistor from pin 1 (pin 2 of TO-100 can) to a stable positive voltage, the ADVFC32 can be operated with a bipolar input voltage. For example, an 80kΩ resistor to +10V causes an additional current of 0.125mA to flow into the integrator so that the net current flow to the integrator is positive even for negative input voltages. At negative full scale input voltage, 0.125mA will flow into the integrator from V_{IN} cancelling out the 0.125mA from the offset resistor, resulting in an output frequency of zero. At positive full scale, the sum of the two currents will be 0.25mA and the output will be at its maximum frequency.

UNIPOLAR V/F, NEGATIVE INPUT VOLTAGE

Figure 3 shows the connection diagram for V/F conversion of negative input voltages. In this configuration full scale output frequency occurs at negative full scale input, and zero output frequency corresponds to zero input voltage.

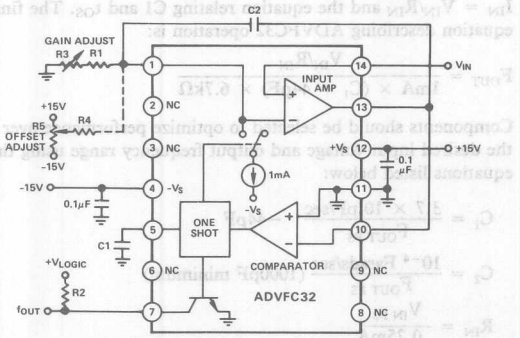

Figure 3. Connection Diagram for V/F Conversion, Negative Input Voltage

A very high impedance signal source may be used since it only drive the noninverting integrator input. Typical input impedance at this terminal is 250MΩ or higher. For V/F conversion of positive input signals the signal generator must be able to source 0.25mA to properly drive the ADVFC32, but for negative V/F conversion the 0.25mA integration current is drawn from ground through R1 and R3.

Circuit operation for negative input voltages is very similar to positive input unipolar conversion described in the previous section. For best operating results use component equations listed in that section.

F/V CONVERSION

Although the mathematics of F/V conversion can be very complex, the basic principle is easy to understand. Figure 4 shows the connection diagram for F/V conversion with TTL input logic levels. Each time the input signal crosses the comparator threshold going negative, the one shot is activated and switches 1mA into the integrator input for a measured time period (determined by C1). As the frequency increases, the amount of charge injected into the integration capacitor increases proportionately. The voltage across the integration capacitor is stabilized when the leakage current through R1 and R3 equals the average current being switched into the integrator. The net result of these two effects is an average output voltage which is proportional to the input frequency. Optimum performance can be obtained by selecting components using the same guidelines and equations listed in the V/F conversion section.

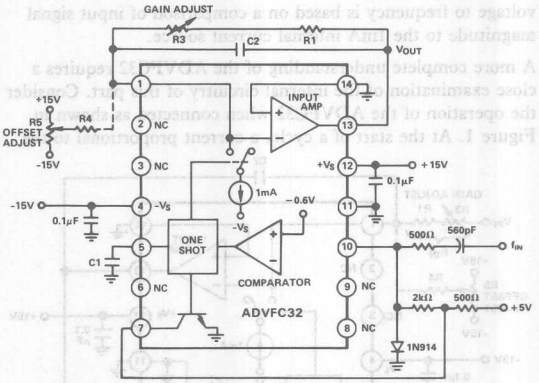

Figure 4. Connection Diagram for F/V Conversion, TTL Input

DECOUPLING

Decoupling power supplies at the device is good practice in any system, but absolutely imperative in high resolution applications. For the ADVFC32, it is important to remember where the voltage transients and ground currents flow. For example, the current drawn through the output pulldown transistor originates from the logic supply, and is directed to ground through pin 11 (pin 8 of TO-100). Therefore, the logic supply should be decoupled near the ADVFC32 to provide a low impedance return path for switching transients. Also, if there is a separate digital ground it should be connected to the analog ground at the ADVFC32. This will prevent ground offsets that could be created by directing the full 8mA output current into the analog ground, and subsequently back to the logic supply.

Although some circuits may operate satisfactorily with the power supplies decoupled at only one location on each board, this practice is not recommended for the ADVFC32. For best results, each supply should be decoupled with 0.1µF capacitor at the ADVFC32. In addition, a larger board level decoupling capacitor of 1µF to 10µF should be located relatively close to the ADVFC32 on each power supply.

COMPONENT TEMPERATURE COEFFICIENTS

The drift specifications of the ADVFC32 do not include temperature effects of any of the supporting resistors or capacitors. The drift of the input resistors R1 and R3 and the timing capacitor C_1 directly affect the overall temperature stability. In the application of Figure 2, a 10ppm/°C input resistor used with a

100ppm/°C capacitor may result in a maximum overall circuit gain drift of:

100ppm/°C (ADVFC32BH) + 100ppm/°C (C1) + 10ppm/°C (R_{IN}) = 210ppm/°C

Although R_{IN} and C_1 have the most pronounced effect on temperature stability, the offset circuit of resistors R4 and R5 may also have a slight effect on the offset temperature drift of the circuit. The offset will change with variations in the resistance of R4 and supply voltage changes. In most applications the offset adjustment is very small, and the offset drift attributable to this circuit will be negligible. In the bipolar mode, however, both the positive reference and the resistor used to offset the signal range will have a pronounced effect on offset drift. A high quality reference and resistor should be used to minimize offset drift errors.

Other circuit components do not directly influence temperature performance as long as their actual values are not so different from nominal value as to preclude operation. This includes integration capacitor C2. A change in the capacitance value of C2 results in a different rate of voltage change across C2, but this is compensated by an equal effect when C2 is discharged by the switched 1mA current source so that no net effect occurs.

The temperature effects of the components described above are the same when the ADVFC32 is configured for negative or bipolar input ranges, or F/V conversion.

OTHER CIRCUIT CONSIDERATIONS

The input amplifier connected to pins 1, 13, and 14 is not a standard operational amplifier. Although it operates like an op amp in most applications, two key differences should be noted. First, the bias current of the positive input is typically 40nA while the bias current of the inverting input is ±8nA. Therefore, any attempt to cancel input offset voltage due to bias currents by matching input resistors will create worse offsets. Second, the output of this amplifier will sink only 1mA, even though it will source as much as 10mA. When used in the F/V mode, the amplifier must be buffered if large sink currents are required.

MICROPROCESSOR OPERATED A/D CONVERTER

With the addition of a few external components the ADVFC32 can be used as a ±10V A/D microprocessor front end. Although the nonlinearity of the ADVFC32 is only 0.05% maximum (0.01% typ), the resolution is much higher, allowing it to be used in 16-bit measurement and control systems where a monotonic transfer function is essential. The resolution of the circuit shown in Figure 5 is dependent on the amount of time allowed to count the ADVFC32 frequency output. Using a full scale frequency of 100kHz, an 8-bit conversion can be made in about 10ms, and a 2 second time period allows a 16-bit measurement, including offset and gain calibration cycles.

As shown in Figure 5, the input signal is selected via the AD7590 input multiplexer. Positive and negative references as well as a ground input are provided to calibrate the A/D. This is very important in systems subject to moderate or extreme temperature changes since the gain temperature coefficient of the ADVFC32 is as high as ±150ppm/°C. By using the calibration cycles, the A/D conversion will be as accurate as the references provided. The AD542 following the input multiplexer provides a high impedance input (10^{12} ohms) and buffers the switch resistance from the relatively low impedance ADVFC32 input.

If higher linearity is required, the ADVFC32 can be operated at 10kHz, but this will require a proportionately longer conversion time. Conversely, the conversion time can be decreased at the expense of nonlinearity by increasing the maximum frequency to as high as 500kHz.

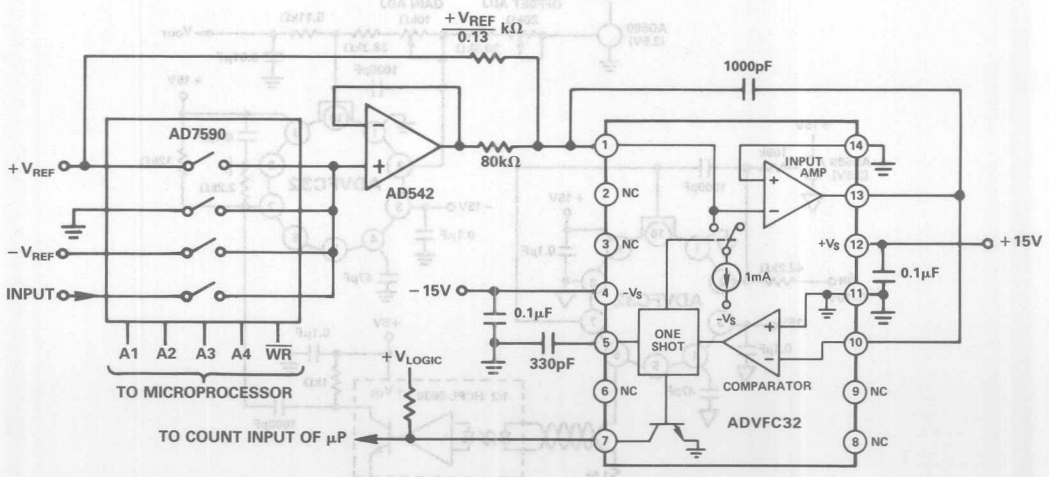

Figure 5. High Resolution, Self-Calibrating, Microprocessor Operated A/D Converter

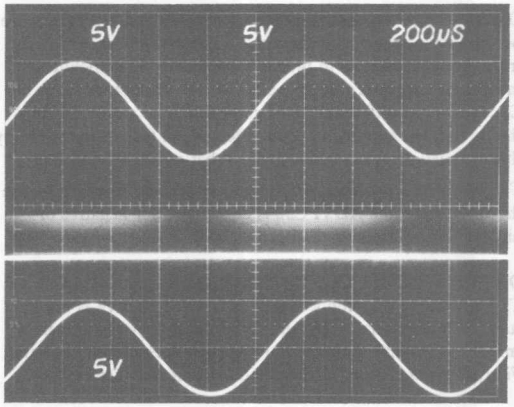

LINK

In many applications, a signal must be sensed at a remote site and sent through a very noisy environment to a central location for further processing. In these cases, even a shielded cable may not protect the signal from noise pickup. The circuit of Figure 6 provides a solution in these cases. Due to the optocoupler and voltage-to-frequency conversion, this data link is extremely insensitive to noise and common mode voltage interference. For even more protection, an optical fiber link substituted for the HCPL2630 will provide common mode rejection of more than several hundred kilovolts and virtually total immunity to electrical noise. For most applications, however, the frequency modulated signal has sufficient noise immunity without using an optical fiber link, and the optocoupler provides common mode isolation up to 3000V dc.

The data link input voltage is changed in a frequency modulated signal by the first ADVFC32. A 42.2kΩ input resistor and a 100kΩ offset resistor set the scaling so that a 0V input signal corresponds to 50kHz, and a 10V input results in the maximum output frequency of 500kHz. A high frequency optocoupler is then used to transmit the signal across any common mode voltage potentials to the receiving ADVFC32. The optocoupler is not necessary in systems where common mode noise is either very small or a constant low level dc voltage. In systems where common mode voltage may present a problem, the connection between the two locations should be through the optocoupler; no power or ground connections need to be made.

The output of the optocoupler drives an ADVFC32 hooked up in the F/V configuration. Since the reconstructed signal at pin 10 has a considerable amount of carrier feedthrough, it is desirable to filter out any frequencies in the carrier range of 50kHz to 500kHz. The frequency response of the F/V converter is only 3kHz due to the pole made by the integrator, so a second 3kHz filter will not significantly limit the bandwidth. With the simple one pole filter shown in Figure 6, the input to output 3dB point is approximately 2kHz, and the output noise is less than 15mV. If a lower output impedance drive is needed, a two pole active filter is recommended as an output stage.

Although the F/V conversion technique used in this circuit is quite simple, it is also very limited in terms of its frequency response and output ripple. The frequency response is limited by the integrator time constant and while it is possible to decrease that time constant, either signal range or output ripple must be sacrificed. The performance of the circuit of Figure 6 is shown in the photograph below. The top trace is the input signal, the middle trace is the frequency-modulated signal at the optocoupler's output, and the bottom trace is the recovered signal at the output of the F/V converter.

Sample-and-Hold Amplifiers

A sample-and-hold amplifier (SHA) is a device that samples an analog input signal then holds the instantaneous value upon the command of a logic control signal. This device is basically an analog memory where a capacitor serves as the storage element. The most prevalent application is in data acquisition in which the SHA is used to capture the last instantaneous sampled analog input voltage prior to a conversion and hold this sample with minimal degradation during the conversion process. In signal processing applications using A/D converters with a subranging or successive approximation architecture, a SHA is used with the A/D converter to maximize the system's full potential bandwidth. Significant improvement in dynamic performance can be made by placing a fast SHA with low aperture jitter ahead of flash A/D converters. Other applications for a SHA include D/A deglitchers, simultaneous sampling systems, peak detectors, pulse stretchers, delay lines, and data distribution systems.

Most SHAs and track-and-holds are identical in both function and circuit implementation. The only distinction between them is in how they are used in the system. A sample-and-hold (SHA) implies that the device samples a signal for a short time and remains in the hold mode for the remainder of the cycle. Conversely, a track-and-hold will spend the majority of the time in the track mode and be switched into the hold mode for brief intervals. Some SHAs compromise their TRACK mode performance in order to improve their HOLD mode performance, and are not recommended for track-and-hold applications. At throughput rates greater than a 1 MHz, this distinction between the two definitions becomes less obvious.

SHA CIRCUITRY AND HARDWARE

The four major functional blocks common to all SHAs are shown in Figure 1. They are the input amplifier, the energy storage device (hold capacitor), the output amplifier, and the switching circuits. The input amplifier serves as a buffer to the signal source, as well as providing current gain to charge the hold capacitor. The hold capacitor usually determines the frequency response of the SHA and retains the last sampled voltage. The output buffer amplifier provides a high impedance to the hold capacitor to minimize the output voltage droop rate. The switching circuit and its driver form the mechanism by which the hold capacitor is alternately switched between the sample and the hold mode of operation. The actual analog switch may be a FET switch or a diode bridge.

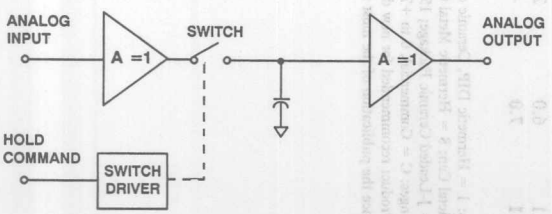

Figure 1. Basic Sample-and-Hold Amplifier

SHA design topologies fall into two categories: open- or closed-loop circuits. Closed-loop SHAs usually contain a high performance input amplifier, a switch, and an output buffer amplifier. The output buffer can be configured as either a voltage follower (i.e., AD583), or as an integrating amplifier (i.e., AD585) which decreases leakage currents by referencing the analog switch to ground. The closed-loop configuration exploits such advantages as gain flexibility, higher accuracy and higher linearity due to overall loop feedback. A tradeoff in accuracy versus speed (i.e., bandwidth, acquisition time, settling time) exists due to overall loop dynamics in which the hold capacitor value helps determine the frequency response and acquisition time. A derivative of this closed-loop topology which is used in the AD680 and AD780 series contains a unique "self correcting" architecture to improve the overall speed and accuracy by nulling out many of the errors accumulated in the sample mode. This particular architecture compromises the performance in the sample mode to achieve high performance in the hold mode.

Conversely, open-loop circuits exploit the characteristics of high-speed unity gain buffer amplifiers and high speed diode bridges to achieve high speed specifications at the expense of overall accuracy (due to the lack of overall loop feedback). A derivative of this topology, used in the AD9100, integrates the high speed diode bridge, a major source of distortion, into the buffer amplifier. This configuration improves upon the overall distortion specifications and provides 10-bit performance at ultrahigh speeds. Another extension of this topology implemented in the SMP-10 and SMP-11 use a super-charger circuit to enhance the slew rate. The super-charger circuit supplements the capacitor charging current whenever the difference between the input and output levels exceeds a given threshold.

PERFORMANCE

The performance of a SHA is described by dynamic and static specifications pertaining to both the sample and the hold mode of operation as well as the transition states between these two modes. Figure 2 displays a complete cycle from the sample-to-hold mode and back with the various error sources exaggerated for tutorial purposes. These groups which define the state of operation of the SHA can be described by both static and dynamic specification. Table I provides an outline of the various dynamic and static specifications associated with the SHA's two modes and transition states. Since a SHA in the sample mode is simply a limited bandwidth amplifier, both the dynamic and static specifications listed in this mode are similar to those of any amplifier. The error sources in the hold mode are due to

Table I. Sample-and-Hold Specifications

Sample Mode	Sample-to-Hold Transition	Hold Mode	Sample-to-Track Transition
STATIC Offset Nonlinearity	STATIC Pedestal (Sample-to-Hold Offset) Pedestal Nonlinearity	STATIC Droop Dielectric Absorption	
DYNAMIC Settling Time Bandwidth Harmonic Distortion Slew Rate	DYNAMIC Switch Aperture Time Effective Aperture Delay Time Aperture Jitter Switch Delay Time Switching Transient	DYNAMIC Feedthrough Distortion + Noise	DYNAMIC Acquisition Time Switching Transient

imperfections in the switch, the output amplifier, and the hold capacitor. Some SHAs specify ac distortion specifications in the hold mode, which provide a simple means of characterizing a particular SHA's performance in a sampled data system.

The specifications of the sample-and-hold transition are particularly relevant in understanding the sources of nonlinearity and thus distortion, as well as in determining the precise time to strobe the device with respect to the input signal. The key specification in the hold-to-sample transition is the acquisition time to a specified percent since this affects the overall achievable throughput rate of a particular sampled data system. Another important specification is the total output noise, which is the rms sum of the output noise of the output amplifier in the hold mode and the dc sampled uncertainty due to aperture jitter. This error source will lower the S/N of the system and thus degrade overall system accuracy. The following definitions of specifications represent a culmination and combination of the various error sources discussed.

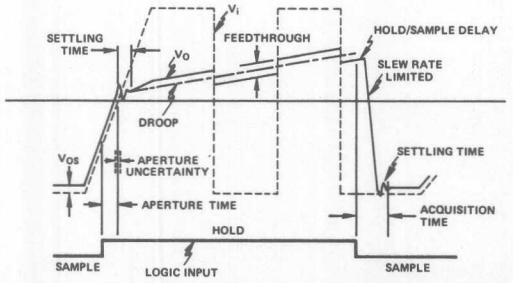

Figure 2. Complete SHA Cycle

DEFINITIONS

Acquisition Time (t_{AQ})
The minimum time for the output voltage to begin tracking the input voltage, to within a specified error band, after the beginning of the sample command. Included are switch-delay time, the slewing interval and settling time for a specified output-voltage change.

Aperture (Delay) Time (t_{AP})
The time required after the hold command for the switch to open fully. The sample is in effect delayed by this interval and the hold command would have to be advanced by this amount for precise timing.

Aperture Jitter or Aperture Uncertainty
The maximum amount of deviation in aperture time from sample to sample, due to noise modulating the phase of the hold command. This deviation manifests itself as an aperture error which is proportional to the slew rate of the sampled analog input signal.

Charge Transfer or Offset Step (Q_T)
The charge transferred to the storage capacitor via stray capacitance when switching to the hold mode. The associated voltage error (Q_T/C) which contributes to pedestal may be reduced by using greater capacitance for storage, but this increases response time.

Droop Rate (dV_{CH}/dt)
The change of the output voltage during the hold mode as a result of leakage or bias currents flowing through the storage capacitor. Its polarity depends on the sources of leakage current or droop current (I_{DR}) within a given device and its magnitude is equal to I_{DR}/C_H.

Feedthrough (F_A)
The fraction of the input signal variation or ac input waveform that appears at the output in the hold mode. It is caused by stray capacitive coupling from the input to the storage capacitor, principally across the open switch.

Full Power Bandwidth (F_P)
The maximum frequency at which rated output voltage E_P can be supplied without significant distortion.

Gain Error
The voltage difference between input and output voltages measured over a specified voltage range, assuming the ideal gain is unity.

Hold Capacitor Charging Current (I_{CH})
The current which charges, or discharges the hold capacitor C_H while the circuit is in the sample mode.

Hold Mode Distortion
Signal-to-Noise Ratio Plus Distortion (S/N+D), Total Harmonic Distortion (THD), Intermodulation Distortion (IMD), and Spurious Free Dynamic Range (SFDR) are all specifications that measure a SHA's performance in the hold mode and its effect on system accuracy.

Hold Mode or Sample-to-Hold Settling Time (t_{HM})
The time for all output transients to settle within a specified error band. Measured from the inception of the hold command.

Hold Step (V_{HS})
Magnitude of step caused in the output voltage by switching the circuit from the sample mode to hold mode.

Input Bias Current (I_B)
Input terminal current with input voltage held at zero volts.

Input Resistance or Impedance (R_{IN})
AC impedance measured as a ratio of input voltage V_{IN} to input current.

Leakage (Droop) Current (I_{DR})
The current which flows out of the hold capacitor C_H while the circuit is operating in the hold mode. In general, droop current is defined positive when its direction is into the C_H pin.

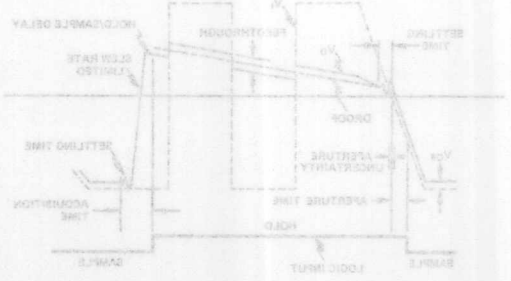
Linearity Error
The maximum deviation from an ideal straight line drawn between the output voltage when V_{IN} = maximum analog voltage, expressed as a percentage of the maximum analog voltage.

Output Resistance (R_O)
An ac change in output voltage as a result of an ac change in load current.

Sample Hold Current Ratio (I_{CH}/I_{DR})
The ratio of the peak charging current available to the droop current.

Sample-to-Hold Offset or Pedestal
A shift in level between the last value in the sample mode and the value to which the output settles in the hold output mode, is the residual step error after the charge transfer is accounted for and/or cancelled. Since it is unpredictable in magnitude and may be a function of the signal, it is also known as offset nonlinearity.

Signal Transfer Nonlinearity
The total input to output hold mode error caused by gain nonlinearity, feedthrough, thermal transient, charge transfer and droop rate. These error terms cannot be corrected by offset and gain adjustments.



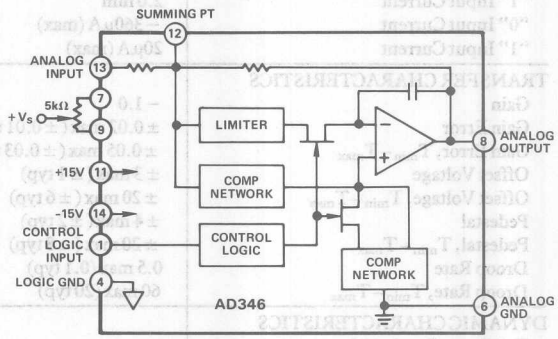
Slew Rate (SR)
The maximum possible rate of change of the output voltage when supplying the rated output. For a SHA, slew rate must be defined with a specified value of holding capacitor C_H.

Total Error
The algebraic sum of the following factors:

i. Zero-Scale Error
ii. Gain Error
iii. Hold Step Change versus $dV_{(S/H)}/dt$
iv. Hold Step Change versus V_{IN}

Voltage Gain (A_V)
The ratio of the output voltage to the input voltage with the circuit operating in the sample mode.

Zero-Scale Error (V_{ZS})
The magnitude of the output voltage when the circuit is switched from sample mode to hold mode while holding the input at zero volts. Zero-Scale Error V_{ZS} is the algebraic sum of the offset voltage and the charge transfer hold step voltage. V_{ZS} can be adjusted to zero.



High Speed Sample-and-Hold Amplifier

AD346

FEATURES

Fast 2.0μs Acquisition Time to ±0.01%
Low Droop Rate: 0.5mV/ms
Low Offset
Low Glitch: <40mV
Aperture Jitter: 400ps
Extended Temperature Range: −55°C to +125°C
Internal Hold Capacitor
MIL-STD-883B Processing Available

FUNCTIONAL BLOCK DIAGRAM

4

PRODUCT DESCRIPTION

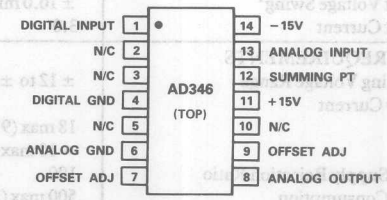
The AD346 is a high speed (2μs to 0.01%), adjustment free sample-and-hold amplifier designed for high throughput rate data acquisition applications. The fast acquisition time (2μs to 0.01%) and low aperture jitter (400ps) make it suitable for use with fast A/D converters to digitize signals up to 97kHz.

The AD346 is complete with an internal hold capacitor and it incorporates a compensation network which minimizes the sample to hold charge offset. The AD346 is also laser trimmed to eliminate the need for external trimming potentiometers.

Typical applications for the AD346 include sampled data systems, D/A deglitchers, peak hold functions, strobed measurement systems and simultaneous sampling converter systems.

The device is available in two versions: the "J" specified for operation over the 0 to +70°C commercial temperature range and the "S" specified over the extended temperature range, −55°C to +125°C.

ORDERING GUIDE



Model	Temperature Range	Package Option*
AD346JD	0 to +70°C	DH-14A
AD346SD	−55°C to +125°C	DH-14A
AD346SD/883B	−55°C to +125°C	DH-14A

*DH-14A = Ceramic DIP. For outline information see Package Outline section.

PRODUCT HIGHLIGHTS

1. The AD346 is an improved second source for other sample and holds of the same pin configuration.
2. The AD346 provides separate analog and digital grounds, thus improving the device's immunity to ground and switching transients.
3. The droop rate is only 0.5mV/ms so that it may be used in slower high accuracy systems without the loss of accuracy.
4. The fast acquisition time and low aperture make it suitable for very high speed data acquisition systems.

GROUNDING

Many data-acquisition components have two or more ground pins which are not connected together within the device. These "grounds" are usually referred to as the Logic Power Return, Analog Common (Analog Power Return), and Analog Signal Ground. These grounds must be tied together at one point, usually at the system power-supply ground. Ideally, a single solid ground would be desirable. However, since current flows through the ground wires and etch stripes of the circuit cards, and since these paths have resistance and inductance, hundreds of millivolts can be generated between the system ground point and the ground pins of the AD346. Separate ground returns should be provided to minimize the current flow in the path from sensitive points to the system ground point. In this way supply currents and logic-gate return currents are not summed into the same return path as analog signals where they would cause measurement errors.

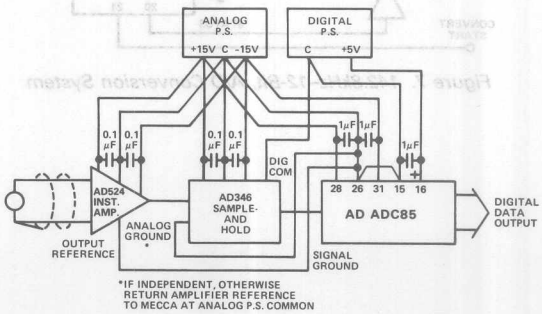

Figure 5. Basic Grounding Practice

speed A/D converter allows accurate digitization of high frequency signals and high throughput rates in multichannel data acqusition systems. The AD346 can be used with a number of different A/D converters to achieve high throughput rates. Figures 6, 7 and 8 show the use of an AD346 with the AD578, AD5240 and AD ADC85.

CLEANLINESS, LEAKAGE AND DROOP

Sample-and-hold amplifiers usually have one or more internal nodes which operate with extremely high impedances in the hold mode. Parasitic leakage at these nodes can degrade the part's droop rate, and ac signals coupled in through parasitic capacitance can introduce noise onto the held output. One such dc leakage path can be produced by the residual oils left on the package after it has been handled with bare fingers. Most normal board cleaning and flux removal procedures will remove these contaminants. For best results finger cots should be used when handling the AD346.

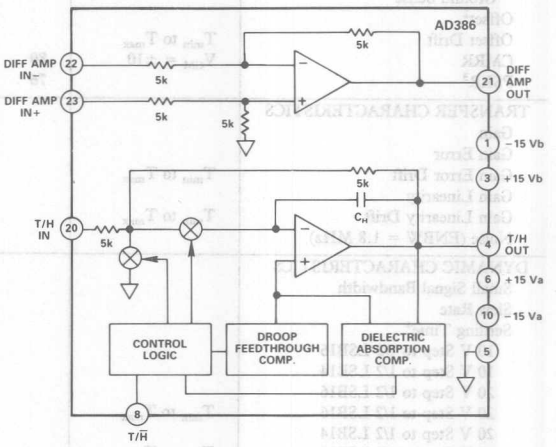
Track-and-Hold Amplifier

AD386

FEATURES

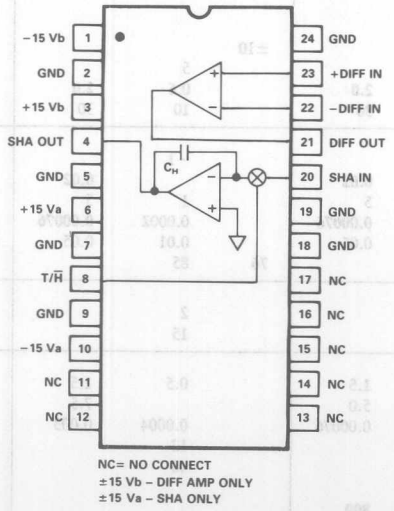
Companion to True 16-Bit A/D Converters
16-Bit Linear (−40°C to +85°C)
14-Bit Linear (−55°C to +125°C)
Fast Acquisition Time: 3.6 μs to 0.00076%
Low Droop Rate: 20 μV/ms
Differential Amplifier for Ground Sense
Low Aperture Jitter: 40 ps

APPLICATIONS



Medical and Analytical Instrumentation
Signal Processing
Multichannel Data Acquisition Systems
Automatic Test Equipment
Guidance and Control
Sonar

PRODUCT DESCRIPTION



The AD386 is a high accuracy, adjustment free track-and-hold amplifier designed for high resolution data acquisition applications. The fast acquisition time (3.6 μs to 75 μV) and low aperture jitter (40 ps) make it ideal for use with fast A/D converters.

The AD386 is complete with an internal hold capacitor, and it incorporates a compensation network which minimizes the track-to-hold charge offset and dielectric absorption. The AD386 also includes an internal differential amplifier for very high accuracy applications.

FUNCTIONAL BLOCK DIAGRAM

Typical applications for the AD386 include sampled data system, peak hold function, strobe measurement system and simultaneous sampling converter systems. When used with autozero and autocalibration techniques, this T/H combined with a high linearity A/D will offer true 16-bit performance (0.00076% linearity) over the industrial temperature range, and 14-bit performance (0.003% linearity) over the military temperature range.

Lead Temperature Range (Soldering 60 sec) . . . . . +300°C

NOTES
[1]Stresses above those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. This is a stress rating only, and functional operation of the device at these or any other conditions above those indicated in the operational section of this specification is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.
[2]For supply voltages less than ±18 V, the absolute maximum input voltage is equal to the supply voltage.

TERMINOLOGY

Aperture Delay: the time required by the internal switch(es) to disconnect the hold capacitor from the input, which produces an effective delay in the sample timing.

Aperture Jitter: the uncertainty in Aperture Delay caused by internal noise and the variation of switching thresholds with signal level. The error caused by aperture jitter depends on the rate of change of the input and as such determines the maximum input frequency which can be sampled without error.

Pedestal: a step change in the output voltage which occurs when switching from track mode to hold mode.

Hold Mode Settling Time: the time required for the pedestal to reach its final value to within a specified fraction of full scale.

Droop: the change in the held output voltage resulting from leakage currents.

Feedthrough: the fraction of input signal variation which appears at the output in hold mode as a result of capacitive coupling.

Dielectric Absorption: the tendency of charges within a capacitor to redistribute themselves over time, resulting in "creep" in the voltage of an open circuit capacitor after a large rapid change.

Acquisition Time: the time required after entering track mode for the voltage on the hold capacitor to settle to within a specified fraction of full scale. This is usually specified for a full-scale step change in output voltage.

Settling Time: the time required in track mode for the output to reach its final value within a specified fraction of full scale following a step change in the input voltage.

Nonlinearity: the degree to which a plot of output versus input deviates from the straight line defined by the end points. It is usually specified as a percentage of full scale.

THEORY OF OPERATION

The architecture of the AD386 differs from that usually encountered in inverting Track-and-Hold (T/H) circuits. The hold capacitor in a conventional T/H (Figure 14) is always connected from the amplifier's output to its inverting input. In track mode switch A is open and switch B is closed. Since the summing junction is a virtual ground, the voltage across the capacitor follows the input. The switches change state in hold mode which disconnects the capacitor from the input and holds the output voltage constant. The clamping action of switch A reduces the variations across switch B, improving feedthrough performance.

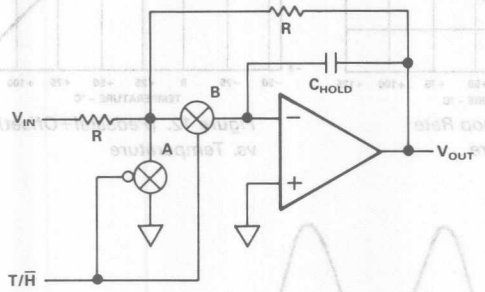

Figure 14. Conventional Inverting Integrator T/H

This circuit forces several tradeoffs. The hold capacitor's charging current is limited by the input resistor. Either the resistor or the capacitor, or both, must be made small to obtain fast acquisition times. A small resistor creates greater demands on the circuit which drives the T/H, while a small capacitor leads to increased pedestal and droop. In addition, the parallel combination of the feedback resistor and the hold capacitor acts as a low pass filter and constrains both bandwidth and acquisition time.

The AD386 uses a four-switch flyback architecture which removes the hold capacitor from the feedback loop during track mode (Figure 15). Switches A and C are open in track mode while switches B and D are closed. This maximizes bandwidth and provides minimum acquisition time because the charging current delivered to the hold capacitor is limited only by the amplifier's output capability. The hold capacitor can be made larger, subject to amplifier stability, since it no longer appears in parallel with the feedback resistor. This helps to reduce droop and pedestal. Switches A and C close in hold mode while switches B and D open, which connects the hold capacitor to the amplifier's inverting input.

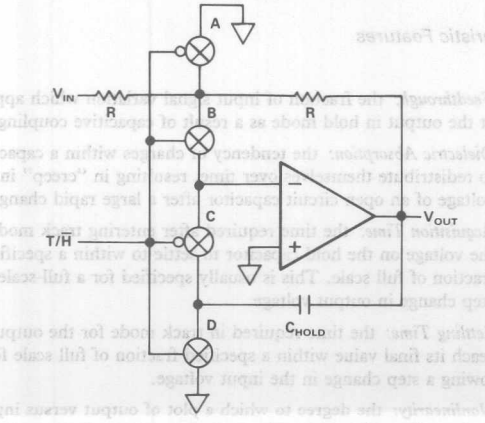

Figure 15. Four-Switch Inverting Flyback T/H

Additional switches and capacitors, not shown in the figure, provide first order cancellation of amplifier and switch leakage currents, switching charge injection, and switch feedthrough. Finally, a small amount of positive feedback is used to reduce dielectric absorption effects.

TRACK-AND-HOLD ERROR CONTRIBUTIONS IN SAMPLED-DATA SYSTEM

Any track-and-hold amplifier imposes performance limits on the system in which it is used. Some of these limits can be derived from the theory of sampled-data systems, some are intrinsic to the T/H, and some depend on details of the system design. Many subtle effects come into play as system resolution increases to 14 or 16 bits, and these can contribute significant errors. Understanding T/H error sources is critical to maintaining signal integrity in a high resolution data acquisition system.

FREQUENCY LIMITATIONS

Three factors set fundamental limits on system performance when digitizing high frequency signals. These are: T/H amplifier bandwidth, aperture uncertainty, and the maximum update rate of the T/H and A/D combination. The track mode bandwidth of the T/H must be significantly greater than the bandwidth of the signals being digitized to prevent the introduction of amplitude and phase errors. The 2 MHz small signal bandwidth of the AD386 attenuates a 35 kHz signal by 0.001 dB and shifts its phase by 1.0 degrees.

There are two different aperture related error terms. The first is aperture delay time, the delay between the HOLD command and the complete opening of internal switches in the T/H. This time amounts to a negative phase delay applied to the input signal because the T/H output can actually continue to track the input for a brief time after the HOLD command. Aperture delay time can be "tuned out" by advancing the assertion of HOLD.

Aperture jitter, the random variations in aperture delay time, causes errors which are directly related to the rate of change of the input signal and which cannot be eliminated by circuit adjustments.

A simple calculation provides the frequency at which aperture jitter produces an error of 1/2 LSB when the input is a full-scale sinusoid. The general result for an N-bit A/D converter is

$$F_{max} = \frac{V_{FS}}{V_{PP}} \times \frac{1}{2^{N+1} \times \pi \times Aperture\ Jitter}$$

where V_{FS} is the A/D converter's input range and V_{PP} is the peak-to-peak value of the input sinusoid. The worst case (minimum) value of F_{max} occurs when V_{PP} is equal to V_{FS}. If the T/H has an aperture jitter of 100 ps and is used with a 16-bit linear A/D, the maximum input frequency is 24.3 kHz.

The same T/H, when used with a 14-bit linear A/D, permits the processing of signals up to 97.1 kHz before aperture jitter-errors become observable. Figure 16 shows these errors as a function of frequency, assuming a full scale input sinusoid, for several values of aperture jitter.

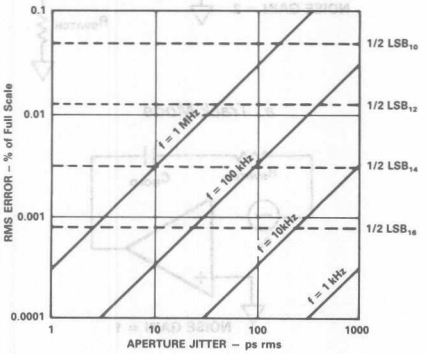

Figure 16. T/H Error vs. Aperture Jitter and Input Frequency

Aperture jitter is often expressed as an rms number. "Peak-to-peak" aperture jitter is usually defined as 6 times this rms value. This comes from probability theory, where 99.7% of the measurements of a random variable will be within 3 standard deviations of the variable's average value. Aperture jitter arises from broadband electrical noise, which is very nearly an ideal random process with a standard deviation equal to its rms value, so multiplication by 6 gives a good approximation to the noise's peak-to-peak value.

A second limit on the input frequency is imposed by the finite time required for signal acquisition and conversion. It is possible to reconstruct any uniformly sampled signal without loss of information provided the sampling rate is at least twice the bandwidth of the input signal; this is the Nyquist criterion, a fundamental result in sampling theory. This limits input frequency to

$$F_{max} = \frac{1}{2 \times (t_{ACQ} + t_{CONV} + t_{AP})}$$

where t_{ACQ} is the T/H acquisition time, T_{CONV} is the time required for the A/D conversion, and T_{AP} is the aperture delay of the T/H. The last term is usually very small and can be ignored. A system composed of a 3.6 μs T/H and a 10 μs A/D can be used successfully to digitize signals with frequency components up to 36.76 kHz. This limit is independent of input signal amplitude. Throughput rates and input frequency ranges for the AD386 in combination with various A/D converters are shown in Table I.

A/D	Conversion Time	Minimum Throughput
ADADC71	50 μs max	18.7 kHz
AD1376/78	17 μs max	48.8 kHz
AD1377	10 μs max	73.5 kHz

Table I. Throughput for AD386 with Various A/D Converters

NONLINEARITIES

Two phenomena directly affect the fidelity of a T/H's transfer function and can degrade system linearity. One of these error sources is track mode nonlinearity. It arises primarily from gain nonlinearity in the T/H's internal amplifier(s). Mismatches in the temperature coefficients of internal resistors may also contribute, but usually do so only for very low frequency signals. The AD386's track mode nonlinearity is about 1/6 16-bit LSB (Figure 17), as is the nonlinearity of the AD386's differential amplifier.

System linearity will also be reduced if the pedestal varies nonlinearly with signal level. Pedestal nonlinearity in the AD386 is below 8 microvolts per volt of input signal, or about 1/2 16-bit LSB.

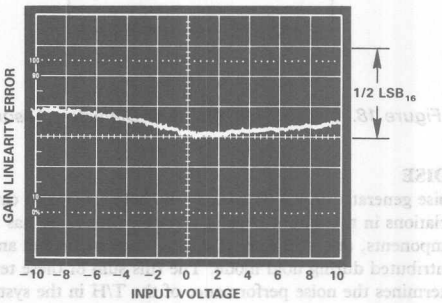

Figure 17. AD386 Track Mode Nonlinearity

FEEDTHROUGH, DROOP, AND DIELECTRIC ABSORPTION

Errors resulting from signal feedthrough and droop must be less than 1/2 LSB in order for the system's linearity to be maintained. The AD386 uses a symmetrical, compensated architecture to minimize both these effects. Feedthrough varies slightly with input frequency from −100 dB below 1 kHz to −86 dB above 100 kHz (Figure 10). This provides 16-bit accuracy for full-scale inputs up to at least 5 kHz and 14-bit performance to beyond 100 kHz.

The circuit's symmetry causes the droop rate to depend on differences in leakage currents between identical junctions under nearly identical bias conditions. The resulting droop is less than 1/2 16-bit LSB (10 V scale) at temperatures up to 85°C and 1/2 14-bit LSB (10 V scale) over the full military temperature range for hold times up to 100 μs.

Capacitors exhibit a memory phenomenon, dielectric absorption (DA), in fast charge, long hold applications. This arises from nonideal behavior of the dielectric material which allows charge storage in the bulk of the dielectric. This bulk charge cannot be removed rapidly because of the long time constant associated with the dielectric's high resistance. A capacitor with dielectric absorption can be modeled as an ideal capacitor in parallel with a series R-C circuit as shown in Figure 18. When such a capacitor is used as the hold capacitor in a T/H the held voltage will tend to creep back towards the voltage held for the previous conversion cycle. The degree and time constant of this behavior depends on the capacitor's dielectric material, as well as on the charge and hold time of the circuit.

4

This causes an apparently nonlinear pedestal because the difference between the currently measured voltage and the previously measured voltage determines the magnitude of the DA error. The AD386 uses a high quality hold capacitor with low intrinsic DA. Residual DA errors are further reduced by laser trimming a compensation network during the manufacturing process. The trimming is performed under typical system timing conditions of 5 μs track, 45 μs hold. The post-trim dielectric absorption error is less than 1/2 16-bit LSB for full-scale changes between samples and hold times between 10 μs and 100 μs.

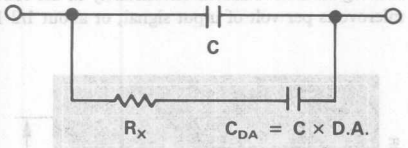

Figure 18. Capacitor Model with Dielectric Absorption

NOISE

Noise generated in a T/H adds to the held signal and causes variations in the output code of an A/D. This noise has two components, one which arises during track mode and another contributed during hold mode. The rms sum of these terms determines the noise performance of the T/H in the system.

Track noise is the noise which gets sampled when entering hold mode. An inverting T/H architecture such as that used in the AD386 has a noise gain of 2. This noise is low pass filtered in the R-C network comprised of the hold capacitor and the switch on resistance (see Figure 19a). The rms value of the track noise is

$$\langle e_{nT} \rangle = (op\ amp\ noise) \times (noise\ gain) \times (ENBW)^{1/2}$$

Op amp noise is the rms sum of the amplifier's broadband voltage noise and the thermal noise contributions of the input and feedback resistors, about 17 nV/$\sqrt{\text{Hz}}$. Other noise sources, including amplifier current noise and switch thermal noise, are negligible. ENBW, the equivalent noise bandwidth, is

$$ENBW = \frac{\pi}{2} \times \frac{BW1 \times BW2}{BW1 + BW2}$$

where BW1 is the small signal bandwidth of the T/H in track mode (2 MHz for the AD386) and BW2 is the corner frequency of the R_{SWITCH}–C_{HOLD} combination (2.7 MHz). The resulting track noise in the AD386 is at most 46 μV rms.

Noise gain is reduced to 1 in hold mode, and input and feedback resistor thermal noise makes no contribution (Figure 19b). The equivalent noise bandwidth now depends on the T/H's small signal bandwidth and the characteristics of the A/D converter used in the system. This is because the signal at the input

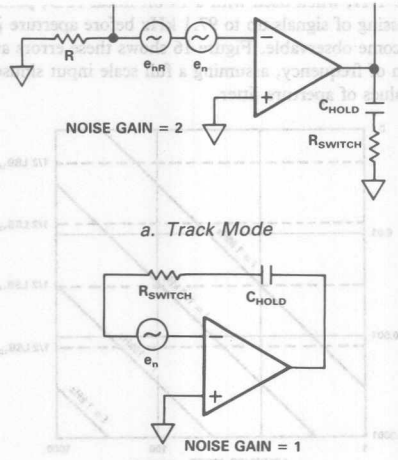

Figure 19. Dominant AD386 Noise Sources

of the comparator in a successive approximation A/D converter is filtered by the converter's input resistance and the summing junction capacitance. ENBW is calculated as before, but now BW1 is the T/H's small signal bandwidth in hold mode (4 MHz for the AD386), and BW2 is the bandwidth of the A/D's input R-C. BW2 is about 700 kHz in the AD ADC71 and AD1376 and roughly 1.7 MHz in the AD1377 and AD1378 (assuming a 10 V span). The respective values of ENBW are 940 kHz and 1.9 MHz. The hold noise contribution of the AD386 is about 16 μV rms when used with the AD ADC71 or AD1376 and 22 μV rms when used with the AD1377 or AD1378; this noise is 30% less for a 20 V span and 40% greater for a 5 V span because changes in the A/D's input resistance cause changes in BW2.

The total noise is the rms sum of these two results:

$$\langle e_n \rangle = [\langle e_{nT}^2 \rangle + \langle e_{nH}^2 \rangle]^{1/2}$$

This yields 49 μV rms and 51 μV rms for the two cases. Track noise dominates in both instances.

When the AD386's differential amplifier is used, its noise contribution will be band limited and sampled by the T/H. The equivalent bandwidth for this noise is also 1.8 MHz and the contribution to the track noise is 46 μV rms. The total track noise is the rms sum of 46 μV and 46 μV, or 65 μV rms, and the overall noise for the complete AD386 used with any of the above A/D converters is at most 70 μV rms.

The rms value represents one standard deviation if the noise has a Gaussian distribution, which is usually the case for wideband electrical noise. If a constant noise-free voltage is sampled a large number of times, the held result will be within one standard deviation of the ideal value 32% of the time, within two standard deviations 95% of the time, and within three standard deviations 99.7% of the time. The entries in Table II were calculated using three standard deviations as the definition of the peak-to-peak noise.

Span	No. Bits	rms Noise LSBs	p-p Noise LSBs
10 V	14	0.11	0.66
20 V	14	0.06	0.36
10 V	16	0.45	2.7
20 V	16	0.23	1.4

Table II. AD386 Noise Contribution as a Function of A/D Span and Resolution

POWER SUPPLY REJECTION

Variations on the power supply lines, both dc and ac, can lead to unwanted changes in the voltage acquired by a T/H. Power supply variations in track mode cause the output voltage, and hence the voltage across the hold capacitor, to vary. PSRR decreases with increasing frequency, making well regulated, low noise linear power supplies and proper bypassing essential in a high resolution data acquisition system.

Equally important, but usually forgotten or omitted, is hold PSRR. This is frequently much worse than track PSRR because parasitic capacitances which are not significant in track mode couple into the extremely high impedance nodes which exist in a T/H during hold mode. This specification is essential to the system designer, as hold mode PSRR often determines the performance required from the system's power supplies. The power supply rejection of the AD386 is specified and characterized in both track and hold modes.

Pedestal arises from the transfer of charge from the internal switching circuitry to the hold capacitor during the transition from track mode to hold mode. Pedestal in some T/H circuits is extremely sensitive to changes in the high and low levels of the external control signal. The AD386 uses an internal +5 V supply and logic buffers to prevent this behavior.

GROUNDING

All voltage measurements in a data acquisition system are eventually referenced to ground. Variations in the "ground" potential through the system resulting from resistive drops of power supply and signal return currents as well as from interference from external sources may add to the signal being digitized and produce false results. The grounding scheme in a high resolution system cannot be left to chance and must be planned as carefully as any other aspect of the system's design. Proper grounding and the reduction of externally induced ground noise are discussed at length in the following Applications section.

Applications

GROUNDING. DECOUPLING, AND LAYOUT CONSIDERATIONS

Many data acquisition systems have two or more ground pins which are not connected together within the device(s). These "grounds" may be referred to as Logic Power Return, Digital Return, Analog Ground, Analog Power Return, Signal Ground, etc., and they must be connected together somewhere within the system to establish a measurement reference point. Good grounding practice dictates that these grounds be tied at a single point, sometimes called a star or "Mecca" ground. In high resolution systems the star point is often located at the A/D, with a single, short, low impedance trace leading from there to the analog supply "common" terminal. The ideal is to use a solid analog ground plane beneath the T/H and A/D as the star point.

Because circuit traces have resistance and inductance, currents in the various ground runs can create voltage differences of hundreds of millivolts between "'ground" in different parts of the system. Power supply and signal ground traces should be separate to prevent summing power supply return currents with analog signal currents, which would lead to measurement errors. It is also important to avoid closed circuit loops in system ground connections. A loop can act as a very effective antenna, coupling voltages created by stray magnetic fields into the measurement system.

Each of the AD386's power supply terminals should be capacitively bypassed to the ground plane as closely as possible to the device. This is best done using 0.01 μF to 0.1 μF ceramic capacitors. High frequency supply noise rejection may be further improved by placing small (4.7 Ω to 10 Ω) carbon composition resistors in series with the supply leads. These resistors, in combination with the ceramic capacitors, act as local low pass filters and prevent crosstalk between system components. The bypassing scheme should also include solid Tantalum capacitors of 1 μF to 10 μF from each supply to ground in the critical areas of the board. Proper grounding and bypassing techniques are shown in Figure 20.

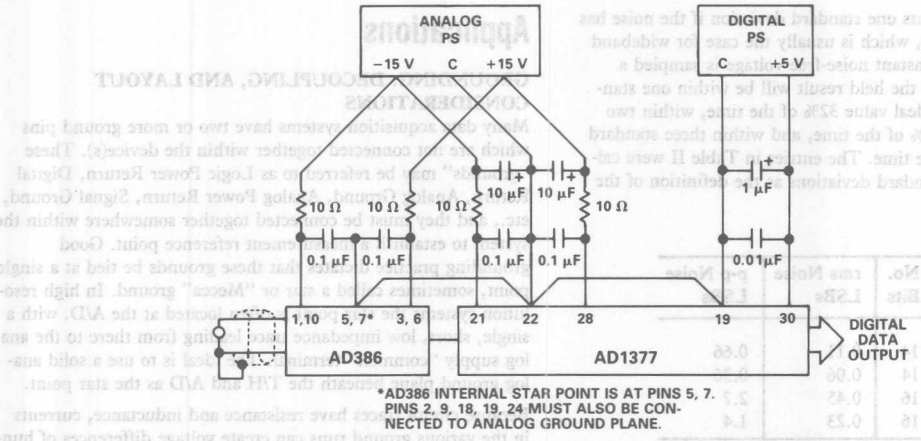
All AD386 ground pins (Pins 2, 5, 7, 9, 18, 19, and 24) should be connected to the analog ground plane.

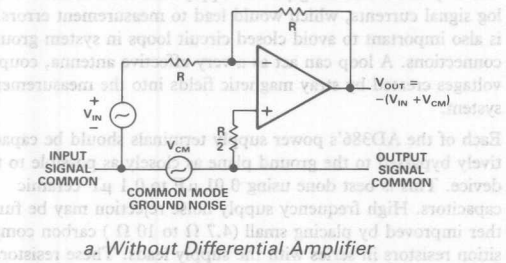
WARNING: Improper bypassing can result in poor settling performance or high frequency oscillations.

The metal cover of the AD386 is internally grounded to provide additional shielding. Do not make any external connection to the cover.

DIFFERENTIAL AMPLIFIER

Many high resolution applications require the ability to sense ground at the signal source. This is especially true in systems with physical or thermal constraints that make it necessary to locate the T/H and A/D at some distance from the transducer. Under these conditions stray electromagnetic fields may cause "ground" at the signal source to be at a different potential from "ground" at the A/D despite the designer's best efforts. This will give rise to measurement errors because the potential difference will appear to be added to the true signal. The AD386's differential amplifier may be used to eliminate this type of ground noise as shown in Figure 21.





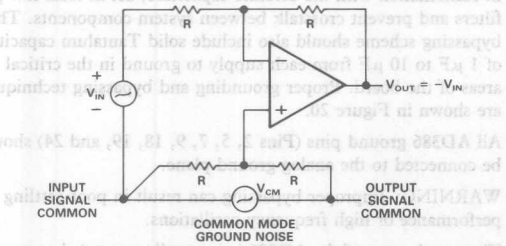


Figure 20. Proper Grounding and Supply Bypassing Techniques for a High Resolution Data Acquisition System

a. Without Differential Amplifier

b. With Differential Amplifier

Figure 21. Effects of Common Mode Noise

In extremely noisy environments it may be necessary to connect the differential amplifier to the signal source with shielded twisted pair cable. The shield should be connected to ground at the transducer and should be left floating at the AD386. This shielding technique is shown in Figure 22. The cable presents a capacitive load, and the signal source must be capable of driving this load without ringing or oscillations. The differential amplifier's noninverting input should be connected to Pin 24 if ground sensing is not required.

Another use of the differential amplifier is to restore signal polarity. Like most high resolution T/H amplifiers, the T/H in the AD386 operates in the inverting mode. The differential amplifier may be used to provide a second inversion so that the T/H output has the same polarity as the sensor output.

The differential amplifier also provides a low dynamic source impedance to the T/H section. This absorbs transients produced when the T/H switches from hold mode to track mode, providing optimal settling performance.

The T/H and differential amplifier have independent power supply connections. This permits a reduction in system power dissipation when the differential amplifier function is not needed.

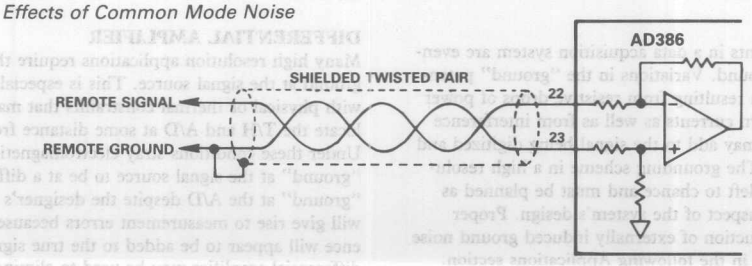

Figure 22. Remote Ground Sensing in a Noisy Environment

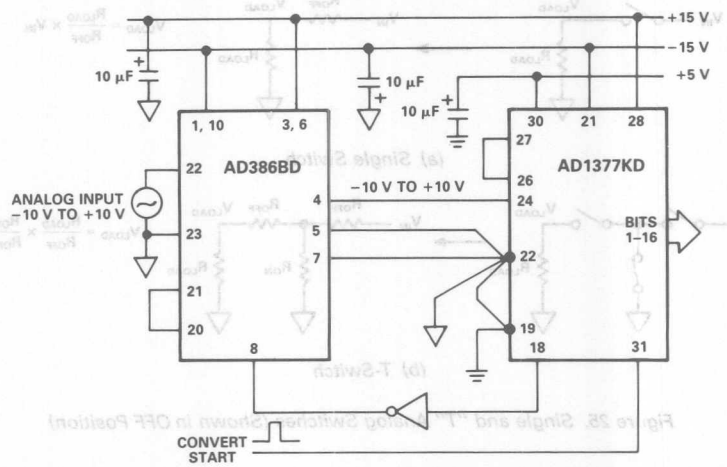

Figure 23. Basic Data Acquisition System (Some Supply Bypassing Omitted for Clarity)

GAIN AND OFFSET ADJUSTMENT

The usual practice in the design of data acquisition systems is to incorporate a single system level trim for offsets and a second for gain errors, rather than to trim each element in the signal processing chain. Traditionally these trims involve potentiometers or fixed resistors. The trims should be designed so that nulling static errors does not introduce new errors such as noise, increased thermal drift, or nonlinearity.

The offset, drift, and gain errors of the AD386 are laser trimmed during manufacture and no external adjustment capabilities are provided. This prevents the introduction of noise through offset adjust terminals and preserves the excellent gain linearity and drift performance. Most A/Ds provide for nulling gain and offset errors with a range sufficient to include the contributions of the AD386. Of course, it is also possible to include calibration routines in the system's software to eliminate mechanical adjustments.

HIGH RESOLUTION DATA ACQUISITION SYSTEM

The essential details of a high resolution data acquisition system using the AD386 are shown in Figure 23. Conversion is initiated by the falling edge of the CONVERT START pulse. This edge drives the A/D's STATUS line high. The inverter then drives the AD386 into hold mode. STATUS remains high throughout the conversion and returns low once the conversion is completed. This allows the AD386 to reenter track mode. The throughputs given in Table I were calculated based upon this circuit configuration.

One drawback of this connection becomes apparent if the system's grounding is marginal. The falling edge of CONVERT-START resets the successive approximation register within the A/D, causing transient currents in both the analog and digital return paths. These transients vary depending on the input signal and the prior conversion result. The same edge also drives the T/H into hold mode. The exact timing relationship of these two events depends upon differences in propagation delays. The T/H's held value may be affected if the A/D reset transient begins before the T/H has fully entered hold mode. The end result is system nonlinearity.

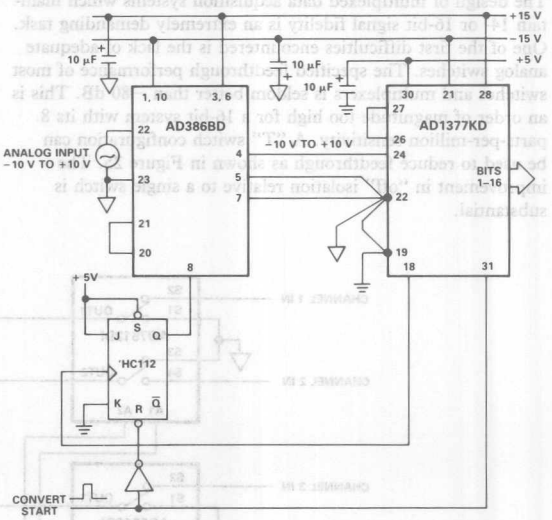

Figure 24. Improved Data Acquisition System (Some Supply Bypassing Omitted for Clarity)

This problem can be avoided with the addition of a flip flop as shown in Figure 24. The rising edge of CONVERT START places the T/H into hold mode before the A/D reset transients begin. The falling edge of STATUS places the AD386 back into track mode. System throughput will be reduced if a long CONVERT START pulse is used. Throughput can be calculated from

$$Throughput = \frac{1}{T_{ACQ} + T_{CONV} + T_{CS}}$$

where T_{ACQ} is the T/H acquisition time, T_{CONV} is the time required for the A/D conversion, and T_{CS} is the duration of CONVERT START. No significant T/H droop error will be introduced provided the width of CONVERT START is small compared with the A/D's conversion time.

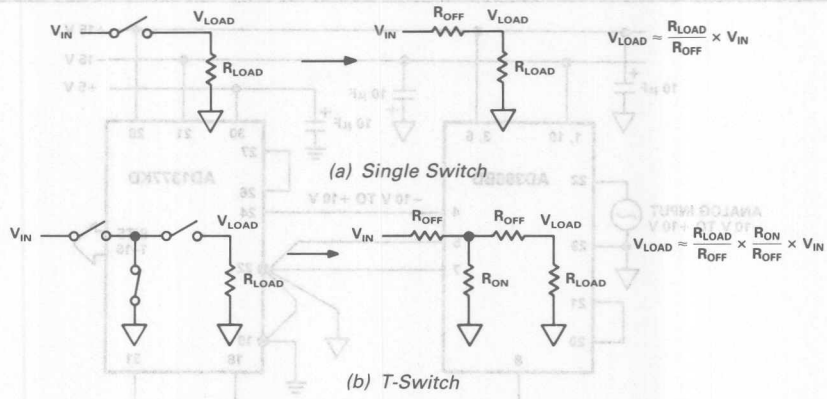

Figure 25. Single and "T" Analog Switches (Shown in OFF Position)

MULTICHANNEL SYSTEMS

The design of multiplexed data acquisition systems which maintain 14- or 16-bit signal fidelity is an extremely demanding task. One of the first difficulties encountered is the lack of adequate analog switches. The specified feedthrough performance of most switches and multiplexers is seldom better than −80 dB. This is an order of magnitude too high for a 16-bit system with its 8 parts-per-million sensitivity. A "T" switch configuration can be used to reduce feedthrough as shown in Figure 25. The improvement in "off" isolation relative to a single switch is substantial.

A few monolithic video T-switch ICs are now available and provide the necessary isolation in the dc-50 kHz frequency range. Unfortunately, these devices have voltage limitations which restrict their utility. It will usually be necessary to design a multiplexer using analog multiplexer and switch ICs. Figure 26 shows a simple 4-channel single-ended T-switch multiplexer and includes a high performance buffer (see below).

The on-resistance of analog switches and multiplexers is a nonlinear function of signal voltage. This will produce severe nonlinearity in a system in which a multiplexer supplies signals

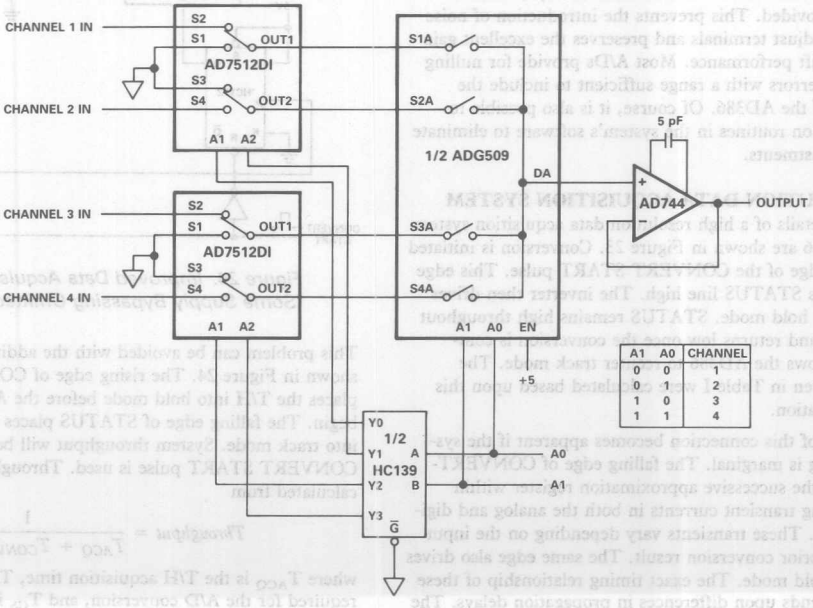

Figure 26. Four-Channel T-Switch Multiplexer (Power Supply Connections Not Shown)

directly to an AD386. A high-impedance buffer between the multiplexer and the T/H's input can solve this problem but may introduce several others.

An op amp in the noninverting gain-of-1 configuration is the obvious candidate for a buffer. The amplifier must settle quickly to maximize system throughput and must be extremely linear to maintain system performance. The linearity of this configuration depends upon the linearity of both the amplifier's open loop gain and common-mode rejection (linear errors in these parameters result only in system gain error, but nonlinear gain and CMRR produce system nonlinearity). Neither of these parameters is specified by most amplifier manufacturers.

A buffer may also increase system noise. Applications which require ground- sensing will require two buffers, resulting in 40% more noise than a one-buffer system.

Finally, a buffer will add its own offset to the signal being measured. Software calibration of the error and its drift is possible using a permanently grounded multiplexer channel.

The AD744 is a nearly ideal buffer for multiplexed systems. This amplifier provides offsets as low as 250 μV and an offset drift of 3 μV/°C while maintaining 16-bit linearity over the −40°C to +85°C temperature range. Typical settling times at room temperature are 2.3 μs (14 bits) and 3.5 μs (16 bits) for the AD744 combined with the AD386's differential amplifier. The increase in noise at the differential amplifier's output will be about 6 μV rms in a one-buffer system and roughly 12 μV rms in a two buffer system (recall that a 16-bit LSB in a 20 volt system is 305 μV). The AD744 is not unity-gain stable, and compensation is required. A 5 pF compensating capacitor is sufficient to ensure stability. The settling times listed above were measured using a 9 pF compensation capacitor which provides greater stability with moderate capacitive loads.

The NE5534 can also be used as a buffer to deliver 16-bit linearity. This amplifier also requires slight compensation to achieve unity-gain stability; 10 pF is sufficient. Settling is somewhat slower than the AD744, about 5 μs to 14 bits and 6 μs to 16 bits, including the AD386's differential amplifier when measured at room temperature. The 5534 has lower voltage noise and will cause only a 1 or 2 μV rms increase in the total noise at the differential amplifier's output. The NE5534 lacks the precision offset and drift performance of the AD744.

Multiplexed throughput can be improved with the proper choice of system timing. If the new input channel is selected while the AD386 is in Hold mode, then multiplexer, buffer, and differential amplifier settling can occur during the A/D conversion. In this case throughput is determined only by the sum of the T/H acquisition and A/D conversion times. The effects of T/H feedthrough must be considered when using this type of overlap in system timing.

There is another solution to many of the problems of multiplexed systems when the speed of channel switching is not critical: relays. Relays should be selected for good shielding, low thermal EMF, and low on-resistance. The only significant drawback of this approach, other than switching speed and size, is power dissipation. In all other respects relays offer a near-perfect solution to the problems of high resolution system design discussed above.

DYNAMIC PERFORMANCE

Dynamic characteristics such as signal-to-noise ratio (SNR) and total harmonic distortion (THD) are important in many signal processing applications. SNR and THD are affected by both the T/H and A/D. The errors contributed by the T/H are generally dependent upon the input signal frequency, while those contributed by the A/D converter usually are not. The dynamic performance of a T/H-A/D pair is characterized using Fast Fourier Transform (FFT) techniques.

Figures 27–31 show the results of several 1024-point FFTs which demonstrate the exceptional distortion and noise performance of the AD386 when combined with the AD1377. These FFTs were obtained using a circuit similar to that of Figure 24. The input signal was processed by both the differential amplifier and T/H sections of the AD386 and was sampled at an 83.333 kHz rate. The AD1377's clock was adjusted to yield an 8.0 μs conversion time, which provided 4.0 μs for the AD386 to acquire each new sample. The vertical scale for these figures is based on a full-scale input referenced as 0 dB. The system was configured for a 10 volt span.

Figures 27 and 28 illustrate the system's low frequency noise and distortion performance. The input frequency is 1.546 kHz. When the input is −0.3 dB, nearly full scale, the largest harmonic component is −102.8 dB (Figure 27). Total harmonic distortion, the rms sum of the second through fifth harmonics, is −99.9 dB. The signal to noise ratio is 89.9 dB. The ultimate noise floor can be determined using a lower level input. Reducing the input level about 20 dB, as in Figure 28, decreases the

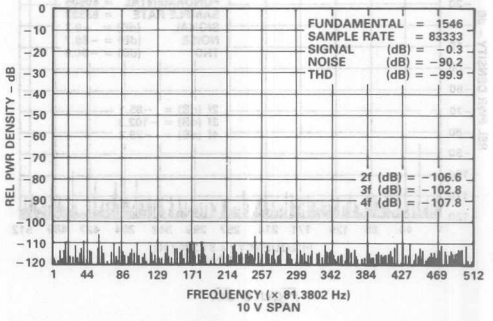

Figure 27.

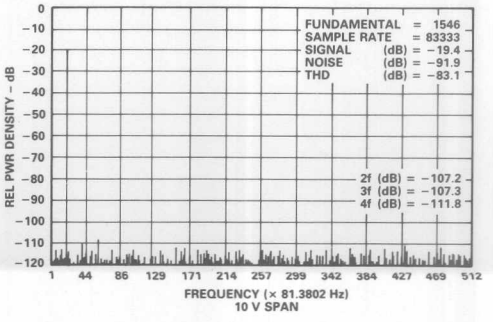

Figure 28.

AD386 noise contribution of about 45 μV rms. The FFT noise floor would improve about 2 dB with the system configured for a 20 volt span because the effect of noise contributed by the AD386 is reduced as a result of the increased LSB size.

System performance just beyond the high end of the audio band is shown in Figure 29. Here the input is a −0.3 dB sinusoid at 21.24 kHz. The only significant harmonic component, the second harmonic, is −91.9 dB with respect to the fundamental, and THD is −91.1 dB. The noise floor is 0.5 dB greater than in Figure 27. The additional noise is contributed by higher-order harmonics, the second through fifth harmonics have been excluded from the noise floor calculations, but higher harmonics are considered to be "noise". These harmonics arise from the AD386's aperture jitter. The additional noise is consistent with an rms jitter of 40 ps.

In Figures 30 and 31, −0.3 dB and −20.1 dB inputs at 40.61 kHz show system performance near the Nyquist frequency. Even at this high frequency a full-scale input produces THD of only −84.6 dB, dominated by the second harmonic at −85.1 dB (Figure 31). In Figure 31 the harmonics have been eliminated by reducing the input level by a factor of 10.

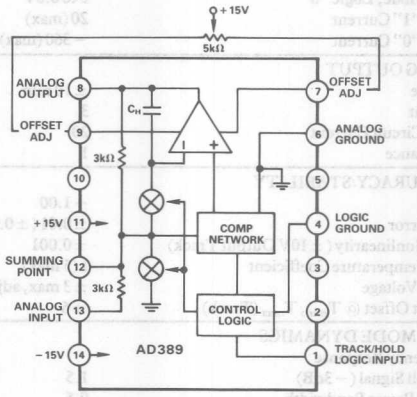
ANALOG DEVICES



High Resolution Track-and-Hold Amplifier

AD389

FEATURES

Companion to High Resolution A/D Converters
Fast Acquisition Time: 2.5μs to ±0.003%
Low Droop Rate: 0.1μV/μs
Aperture Jitter: 400ps
Internal Hold Capacitor
Unity Gain Inverter
Low Power Dissipation: 300mW

FUNCTIONAL BLOCK DIAGRAM

PRODUCT DESCRIPTION

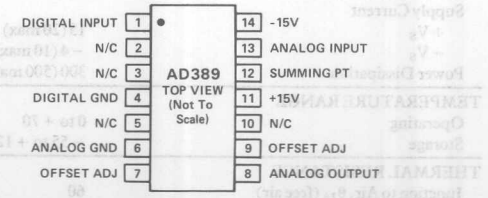
The AD389 is a high accuracy, adjustment free track-and-hold amplifier designed for high resolution data acquisition applications. The fast acquisition time (2.5μs to ±0.003%) and low aperture jitter (400ps) make it suitable for use with fast A/D converters to digitize signals up to 40kHz.

The AD389 is complete with an internal hold capacitor and it incorporates a compensation network which minimizes the sample to hold charge offset.

Typical applications for the AD389 include sampled data systems, peak hold functions, strobed measurement systems and simultaneous sampling converter systems. When used with autozero and autocalibration techniques, this T/H combined with a high linearity A/D will offer 14-bit performance over the converter's full no-missing-code temperature range.

The device is available in two versions: the "K" specified for operation over the 0 to +70°C commercial temperature range and the "B" specified over the full industrial temperature range, −25°C to +85°C. High reliability processing is available; contact factory for information.

PRODUCT HIGHLIGHTS



1. The AD389 is the ideal companion track-and-hold amplifier to 14-bit accurate A/D converters.
2. The AD389 provides separate analog and digital grounds, thus improving the device's immunity to ground and switching transients.
3. The droop rate is only 0.1μV/μs so that it may be used in slower high resolution systems without the loss of accuracy.
4. The fast acquisition time and low aperture make it suitable for high speed data acquisition systems and digital audio recording.
5. The AD389 T/H amplifier is ideal for applications requiring wide dynamic range.
6. Clever circuit design eliminates any measurable thermal tail (see Figures 1a and 1b).

ORDERING GUIDE

Model	Temperature Range	Package Option*
AD389KD	0 to +70°C	DH-14A
AD389BD	−25°C to +85°C	DH-14A

*DH-14A = Ceramic DIP. For outline information see Package Information section.

PIN CONFIGURATION

AD389—SPECIFICATIONS (typical @ +25°C and nominal power supply voltage of ±15 V unless otherwise noted)

Model	AD389KD	AD389BD	Units
ANALOG INPUT			
Voltage Range	±10 min	*	V
Overvoltage, no damage	±15 max	*	V

OFFSET ADJUST TRIM

In most data acquisition systems only one offset adjustment is made. In many cases it is the offset adjust of the ADC that is used to cancel all other accumulated system offsets. The offset or pedestal of the AD389 can be nulled by means of 5kΩ potentiometer between pins 7, 9, and 11. If the offset of the AD389 is not adjusted, then connect pins 7 and 9 to pin 14, the negative supply. Otherwise the high impedance of the null pin together with parasitic capacitances can cause tail effects.

pins which are not connected together within the device. These "grounds" are usually referred to as the Logic Power Return, Analog Common (Analog Power Return), and Analog Signal Ground. These grounds must be tied together at one point, preferably as close to the A-to-D converter as possible. Ideally, a single solid ground would be desirable. However, since current flows through the ground wires and etch stripes of the circuit cards, and since these paths have resistance and inductance, hundreds of millivolts can be generated between the system ground point and the ground pins of the AD389. Separate ground returns should be provided to minimize the current flow in the path from sensitive points to the system ground point. In this way supply currents and logic-gate return currents are not summed into the same return path as analog signals where they would cause measurement errors.

DECOUPLING

The AD389 can only settle accurately and fast if the power supplies do not change during transients. Therefore, it is necessary to put 0.1μF decoupling capacitors right between the supply and analog ground pins and to have 10μF tantalum caps close by.

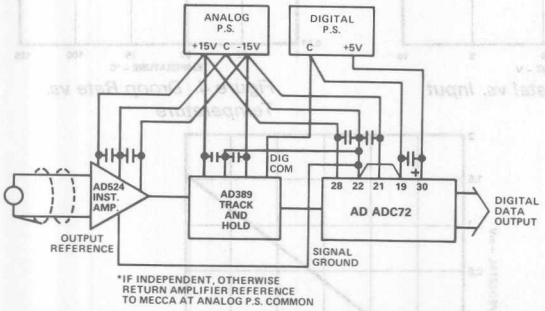

Figure 8. Basic Grounding and Decoupling Practice

speed A/D converter allows accurate digitization of high frequency signals and high throughput rates in multichannel data acquisition systems. Figure 9 shows the use of an AD389 with the AD376.

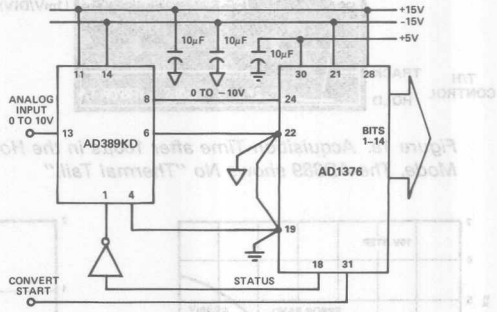

Figure 9. 20kHz-14-Bit, A/D Conversion System

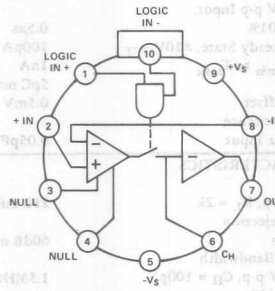
CLEANLINESS, LEAKAGE AND DROOP

Track-and-hold amplifiers usually have one or more internal nodes which operate with extremely high impedances in the hold mode. Parasitic leakage at these nodes can degrade the part's droop rate, and ac signals coupled in through parasitic capacitance can introduce noise onto the held output. One such dc leakage path can be produced by the residual oils left on the package after it has been handled with bare fingers. Most normal board cleaning and flux removal procedures will remove these contaminants. For best results finger cots should be used when handling the AD389.

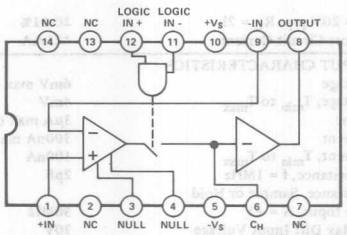
Sample-and-Hold Amplifier



AD582

FEATURES

Suitable for 12-Bit Applications
High Sample/Hold Current Ratio: 10^7
Low Acquisition Time: 6μs to 0.1%
Low Charge Transfer: <2pC
High Input Impedance in Sample-and-Hold Modes
Connect in Any Op Amp Configuration
Differential Logic Inputs
MIL-STD-883 Compliant Versions Available



PIN CONFIGURATIONS

PRODUCT DESCRIPTION

The AD582 is a low-cost integrated circuit sample-and-hold amplifier consisting of a high performance operational amplifier, a low leakage analog switch and a JFET integrating amplifier – all fabricated on a single monolithic chip. An external holding capacitor, connected to the device, completes the sample-and-hold function.

With the analog switch closed, the AD582 functions like a standard op amp; any feedback network may be connected around the device to control gain and frequency response. With the switch open, the capacitor holds the output at its last level, regardless of input voltage.

Typical applications for the AD582 include sampled data systems, D/A deglitchers, analog de-multiplexers, auto null systems, strobed measurement systems and A/D speed enhancement.

The device is available in two versions: the "K" specified for operation over the 0 to +70°C commercial temperature range and the "S" specified over the extended temperature range, –55°C to +125°C. All versions may be obtained in either the hermetic sealed, TO-100 can or the TO-116 DIP.

PRODUCT HIGHLIGHTS

1. The specially designed input stage presents a high impedance to the signal source in both sample and hold modes (up to ±12V). Even with signal levels up to $\pm V_S$, no undesirable signal inversion, peaking or loss of hold voltage occurs.
2. The AD582 may be connected in any standard op amp configuration to control gain or frequency response and provide signal inversion, etc.
3. The AD582 offers a high, sample-to-hold current ratio: 10^7. The ratio of the available charging current to the holding leakage current is often used as a figure of merit for a sample and hold circuit.
4. The AD582 has a typical charge transfer less than 2pC. A low charge transfer produces less offset error and permits the use of smaller hold capacitors for faster signal acquisition.
5. The AD582 provides separate analog and digital grounds, thus improving the device's immunity to ground and switching transients.
6. The AD582 is available in versions compliant with MIL-STD-883. Refer to the Analog Devices Military Products Databook or current AD582/883B data sheet for detailed specifications.

APPLYING THE AD582

Both the inverting and non-inverting inputs are brought out to allow op amp type versatility in connecting and using the AD582. Figure 1 shows the basic non-inverting unity gain connection requiring only an external hold capacitor and the usual power supply bypass capacitors. An offset null pot can be added for more critical applications.

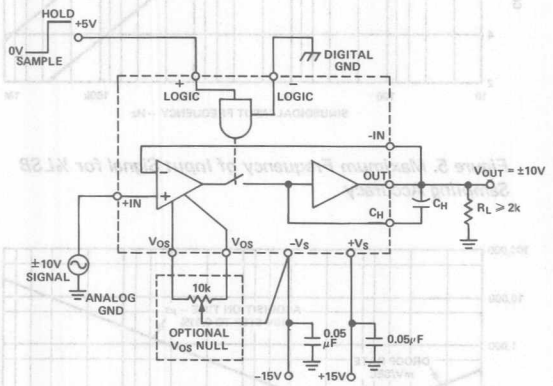

Figure 1. Sample and Hold with A = +1

Figure 2 shows a non-inverting configuration where voltage gain, A_V, is set by a pair of external resistors. Frequency shaping or non-linear networks can also be used for special applications.

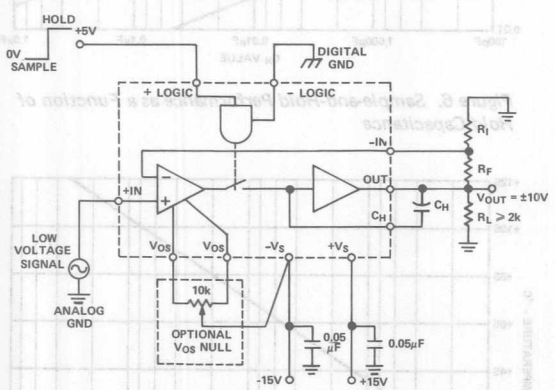

Figure 2. Sample and Hold with A = (1 + R_F/R_I)

The hold capacitor, C_H, should be a high quality polystyrene (for temperatures below +85°C) or Teflon type with low dielectric absorption. For high speed, limited accuracy applications, capacitors as small as 100pF may be used. Larger values are required for accuracies of 12 bits and above in order to minimize feedthrough, sample to hold offset and droop errors (see Figure 6). Care should be taken in the circuit layout to minimize coupling between the hold capacitor and the digital or signal inputs.

In the hold mode, the output voltage will follow any change in the $-V_S$ supply. Consequently, this supply should be well regulated and filtered.

Biasing the +Logic Input anywhere between -6V to +0.8V with respect to the -Logic will set the sample mode. The hold mode will result from any bias between +2.0V and ($+V_S$ - 3V). The sample and hold modes will be controlled differentially with the absolute voltage at either logic input ranging from $-V_S$ to within 3V of $+V_S$ (V_S - 3V). Figure 3 illustrates some examples of the flexibility of this feature.

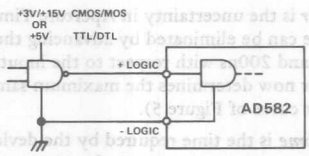

Figure 3A. Standard Logic Connection

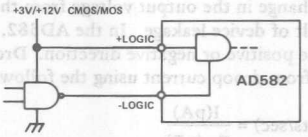

Figure 3B. Inverted Logic Sense Connection

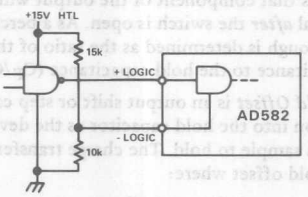

Figure 3C. High Threshold Logic Connection

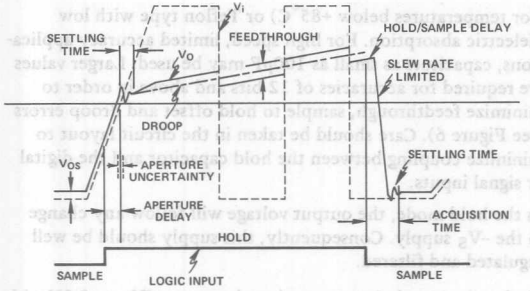

Figure 4. Pictorial Showing Various S/H Characteristics

Aperture Delay is the time required after the "hold" command until the switch is fully open and produces a delay in the effective sample timing. Figure 5 is a plot giving the maximum frequency at which the AD582 can sample an input with a given accuracy (lower curve).

Aperture Jitter is the uncertainty in Aperture Time. The Aperture Time can be eliminated by advancing the sample-to-hold command 200ns with respect to the input signal. The Aperture Jitter now determines the maximum sampling frequency (upper curve of Figure 5).

Acquisition Time is the time required by the device to reach its final value within a given error band after the sample command has been given. This includes switch delay time, slewing time and settling time for a given output voltage change.

Droop is the change in the output voltage from the "held" value as a result of device leakage. In the AD582, droop can be in either the positive or negative direction. Droop rate may be calculated from droop current using the following formula:

$$\frac{\Delta V}{\Delta T}\,(\text{Volts/sec}) = \frac{I(\text{pA})}{C_H(\text{pF})}$$

(See also Figure 6.)

Feedthrough is that component of the output which follows the input signal *after* the switch is open. As a percentage of the input, feedthrough is determined as the ratio of the feedthrough capacitance to the hold capacitance (C_F/C_H).

Sample-to-Hold Offset is an output shift or step caused by charge injection into the hold capacitor as the device is switched from sample to hold. The charge transfer generates a sample-to-hold offset where:

$$\text{S/H Offset (V)} = \frac{\text{Charge (pC)}}{C_H\,(\text{pF})}$$

This offset also has a dc component as shown in Figure 6.

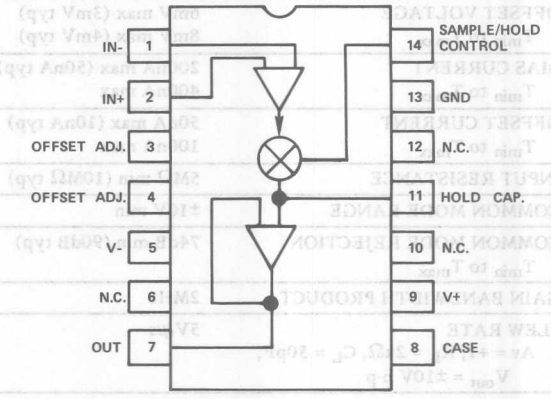
ANALOG DEVICES



Sample-and-Hold Amplifier

AD583

FEATURES

High Sample-to-Hold Current Ratio: 10^6
High Slew Rate: 5V/μs
High Bandwidth: 2MHz
Low Aperture Time: 50ns
Low Charge Transfer: 10pC
DTL/TTL Compatible
May Be Used as Gated Op Amp

PIN CONFIGURATION

PRODUCTION DESCRIPTION

The AD583 is a monolithic sample-and hold circuit consisting of a high performance operational amplifier in series with a low leakage analog switch and unity gain amplifier. An external hold capacitor, connected to the switch output, completes the sample-and-hold or track-and-hold function.

With the analog switch closed, the AD583 functions like a standard op amp; any feedback network may be connected around the device to control gain and frequency response. With the switch open the capacitor holds the output at its previous level.

The AD583 may also be used as a versatile operational amplifier with a gated output for applications such as analog switches, peak holding circuits, etc.

PRODUCT HIGHLIGHTS

1. Sample-and-hold operation is obtained with the addition of one external capacitor.
2. Low charge transfer (10pC) and high sample-to-hold current ratio insure accurate tracking.
3. Any gain or frequency response is available using standard op amp feedback networks.
4. High slew rate and low aperture time permit sampling of rapidly changing signals.
5. Output, gated through a low leakage analog switch, also makes the AD583 useful for applications such as analog switches, peak holding circuits, etc.

SPECIFICATIONS (typical @ +25°C, hold capacitor of 1000pF and ±15V dc unless otherwise specified)

NC = NO CONNECT

PRODUCT DESCRIPTION

The AD585 is a complete monolithic sample-and-hold circuit consisting of a high performance operational amplifier in series with an ultralow leakage analog switch and a FET input integrating amplifier. An internal holding capacitor and matched applications resistors have been provided for high precision and applications flexibility.

The performance of the AD585 makes it ideal for high speed 10- and 12-bit data acquisition systems, where fast acquisition time, low sample-to-hold offset, and low droop are critical. The AD585 can acquire a signal to ±0.01% in 3μs maximum, and then hold that signal with a maximum sample-to-hold offset of 3mV and less than 1mV/ms droop, using the on-chip hold capacitor. If lower droop is required, it is possible to add a larger external hold capacitor.

The high-speed analog switch used in the AD585 exhibits aperture jitter of 0.5ns, enabling the device to sample full-scale (20V peak-to-peak) signals at frequencies up to 78kHz with 12-bit precision.

The AD585 can be used with any user-defined feedback network to provide any desired gain in the sample mode. On-chip precision thin-film resistors can be used to provide gains of +1, −1, or +2. Output impedance in the hold mode is sufficiently low to maintain an accurate output signal even when driving the dynamic load presented by a successive-approximation A/D converter. However, the output is protected against damage from accidental short circuits.

The control signal for the HOLD command can be either active high or active low. The differential HOLD signal is compatible with all logic families, if a suitable reference level is provided. An on-chip TTL reference level is provided for TTL compatibility.

The AD585 is available in three performance grades. The JP grade is specified for the 0 to +70°C commercial temperature range and packaged in a 20-pin PLCC. The AQ grade is specified for the −25°C to +85°C industrial temperature range and is packaged in a 14-pin cerdip. The SQ and SE grades are specified for the −55°C to +125°C military temperature range and are packaged in a 14-pin cerdip and 20-pin LCC.

PRODUCT HIGHLIGHTS

1. The fast acquisition time (3μs) and low aperture jitter (0.5ns) make it the first choice for very high speed data acquisition systems.
2. The droop rate is only 1.0mV/ms so that it may be used in slower high accuracy systems without the loss of accuracy.
3. The low charge transfer of the analog switch keeps sample-to-hold offset below 3mV with the on-chip 100pF hold capacitor, eliminating the trade-off between acquisition time and S/H offset required with other SHAs.
4. The AD585 has internal pretrimmed application resistors for applications versatility.
5. The AD585 is complete with an internal hold capacitor for ease of use. Capacitance can be added externally to reduce the droop rate when long hold times and high accuracy are required.
6. The AD585 is recommended for use with 10- and 12-bit successive-approximation A/D converters such as AD573, AD574A, AD674A, AD7572 and AD7672.
7. The AD585 is available in versions compliant with MIL-STD-883. Refer to the Analog Devices Military Products Databook or current AD585/883B data sheet for detailed specifications.

SAMPLED DATA SYSTEMS

In sampled data systems there are a number of limiting factors in digitizing high frequency signals accurately. Figure 9 shows pictorially the sample-and-hold errors that are the limiting factors. In the following discussions of error sources the errors will be divided into the following groups: 1. Sample-to-Hold Transition, 2. Hold Mode and 3. Hold-to-Sample Transition.

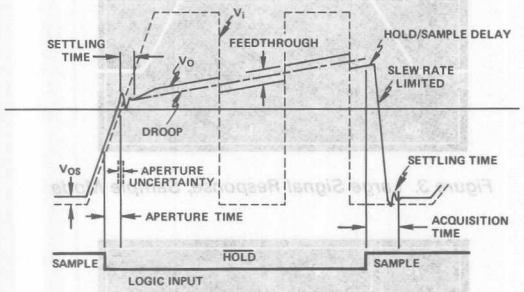

Figure 9. Pictorial Showing Various S/H Characterstics

SAMPLE-TO-HOLD TRANSITION

The aperture delay time is the time required for the sample-and-hold amplifier to switch from sample to hold. Since this is effectively a constant then it may be tuned out. If however, the aperture delay time is not accounted for then errors of the magnitude as shown in Figure 10 will result.

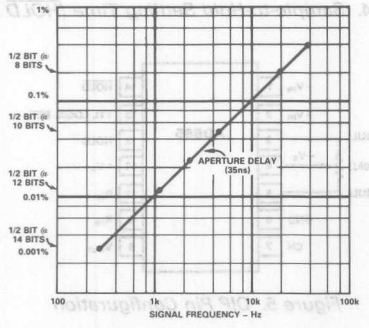

Figure 10. Aperture Delay Error vs. Frequency

To eliminate the aperture delay as an error source the sample-to-hold command may be advanced with respect to the input signal.

Once the aperture delay time has been eliminated as an error source then the aperture jitter which is the variation in aperture delay time from sample-to-sample remains. The aperture jitter is a true error source and must be considered. The aperture jitter is a result of noise within the switching network which modulates the phase of the hold command and is manifested in the variations in the value of the analog input that has been held. The aperture error which results from this jitter is directly related to the dV/dT of the analog input.

The error due to aperture jitter is easily calculated as shown below. The error calculation takes into account the desired accuracy corresponding to the resolution of the N-bit A/D converter.

$$F_{max} = \frac{2^{-(N+1)}}{\pi\ (\text{Aperture Jitter})}$$

For an application with a 10-bit A/D converter with a 10V full scale to a 1/2LSB error maximum.

$$F_{max} = \frac{2^{-(10+1)}}{\pi\ (0.5 \times 10^{-9})}$$

$$F_{max} = 310.8\text{kHz}.$$

For an application with a 12-bit A/D converter with a 10V full scale to a 1/2LSB error maximum:

$$F_{max} = \frac{2^{-(12+1)}}{\pi\ (0.5 \times 10^{-9})}$$

$$F_{max} = 77.7\text{kHz}.$$

Figure 11 shows the entire range of errors induced by aperture jitter with respect to the input signal frequency.

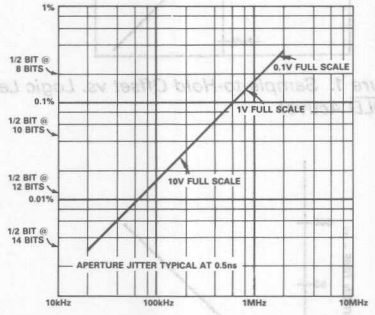

Figure 11. Aperture Jitter Error vs. Frequency

Sample-to-hold offset is caused by the transfer of charge to the holding capacitor via the gate capacitance of the switch when switching into hold. Since the gate capacitance couples the switch-control voltage applied to the gate on to the hold capacitor, the resulting sample-to-hold offset is a function of the logic level.

The logic inputs were designed for application flexibility and, therefore, a wide range of logic thresholds. This was achieved by using a differential input stage for HOLD and $\overline{\text{HOLD}}$. Figure 1 shows the change in the sample-to-hold offset voltage based upon an independently programmed reference voltage. Since the input stage is a differential configuration, the offset voltage is a function of the control voltage range around the programmed threshold voltage.

The sample-to-hold offset can be reduced by adding capacitance to the internal 100pF capacitor and by using $\overline{\text{HOLD}}$ instead of HOLD. This may be easily accomplished by adding an external capacitor between Pins 7 and 8. The sample-to-hold offset is then governed by the relationship:

$$\text{S/H Offset (V)} = \frac{\text{Charge (pC)}}{C_H\ \text{Total (pF)}}$$

For the AD585 in particular it becomes:

$$\text{S/H Offset (V)} = \frac{0.3\ \text{pC}}{100\text{pF} + (C_{EXT})}$$

The addition of an external hold capacitor also affects the acquisition time of the AD585. The change in acquisition time with respect to the C_{EXT} is shown graphically in Figure 2.

HOLD MODE

In the hold mode there are two important specifications that must be considered; feedthrough and the droop rate. Feedthrough errors appear as an attenuated version of the input at the output while in the hold mode. Hold-Mode feedthrough varies with frequency, increasing at higher frequencies. Feedthrough is an important specification when a sample and hold follows an analog multiplexer that switches among many different channels.

Hold-mode droop rate is the change in output voltage per unit of time while in the hold mode. Hold mode droop originates as leakage from the hold capacitor, of which the major leakage current contributors are switch leakage current and bias current. The rate of voltage change on the capacitor dV/dT is the ratio of the total leakage current I_L to the hold capacitance C_H.

$$\text{Droop Rate} = \frac{dV_{OUT}}{dT}\ (\text{Volts/Sec}) = \frac{I_L(\text{pA})}{C_H(\text{pF})}$$

For the AD585 in particular;

$$\text{Droop Rate} = \frac{100\text{pA}}{100\text{pF} + (C_{EXT})}$$

Additionally the leakage current doubles for every 10°C increase in temperature above 25°C; therefore, the hold-mode droop rate characteristic will also double in the same fashion. The hold-mode droop rate can be traded-off with acquisition time to provide the best combination of droop error and acquisition time. The tradeoff is easily accomplished by varying the value of C_{EXT}.

Since a sample and hold is used typically in combination with an A/D converter, then the total droop in the output voltage has to be less than 1/2LSB during the period of a conversion. The maximum allowable signal change on the input of an A/D converter is:

$$\Delta V \text{ max} = \frac{\text{Full Scale Voltage}}{2^{(N+1)}}$$

Once the maximum ΔV is determined then the conversion time of the A/D converter (T_{CONV}) is required to calculate the maximum allowable dV/dT.

$$\frac{dV \text{ max}}{dt} = \frac{\Delta V \text{ max}}{T_{CONV}}$$

The maximum $\frac{dV \text{ max}}{dT}$ as shown by the previous equation is the limit not only at 25°C but at the maximum expected operating temperature range. Therefore, over the operating temperature range the following criteria must be met ($T_{OPERATION} - 25°C$) $= \Delta T$.

$$\frac{dV\ 25°C}{dT} \times 2^{\frac{(\Delta T°C)}{10°C}} \leq \frac{dV \text{ max}}{dT}$$

NYQUIST THEOREM

The Nyquist theorem states that a band-limited signal which is sampled at a rate at least twice the maximum signal frequency can be reconstructed without loss of information. This means that a sampled data system must sample, convert and acquire the next point at a rate at least twice the signal frequency. Thus the maximum input frequency is equal to

$$f_{MAX} = \frac{1}{2(T_{ACQ} + T_{CONV} + T_{AP})}$$

Where T_{ACQ} is the acquisition time of the sample-to-hold amplifier, T_{AP} is the maximum aperture time (small enough to be ignored) and T_{CONV} is the conversion time of the A/D converter.

DATA ACQUISITION SYSTEMS

The fast acquisition time of the AD585 when used with a high speed A/D converter allows accurate digitization of high frequency signals and high throughput rates in multichannel data acquisition systems. The AD585 can be used with a number of different A/D converters to achieve high throughput rates. Figures 12 and 13 show the use of an AD585 with the AD578 and AD574A.

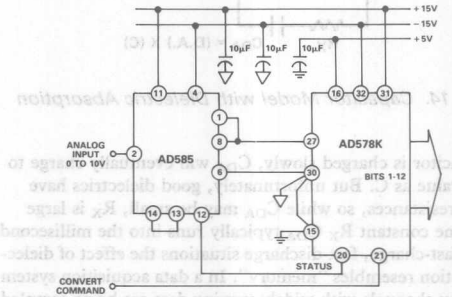

Figure 12. A/D Conversion System, 117.6kHz Throughput 58.8kHz max Signal Input

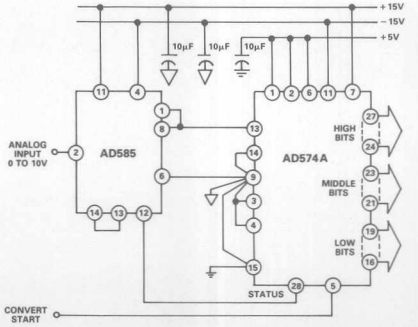

Figure 13. 12 Bit A/D Conversion System, 26.3kHz Throughput Rate, 13.1kHz max Signal Input

LOGIC INPUT

The sample-and-hold logic control was designed for versatile logic interfacing. The HOLD and $\overline{\text{HOLD}}$ inputs may be used with both low and high level CMOS, TTL and ECL logic systems. Logic threshold programmability was achieved by using a differential amplifier as the input stage for the digital inputs. A predictable logic threshold may be programmed by referencing either HOLD or $\overline{\text{HOLD}}$ to the appropriate threshold voltage. For example, if the internal 1.4V reference is applied to $\overline{\text{HOLD}}$ an input signal to HOLD between +1.8V and $+V_S$ will place the AD585 in the hold mode. The AD585 will go into the sample mode for this case when the input is between $-V_S$ and +1.0V. The range of references which may be applied is from ($-V_S$ +4V) to ($+V_S$ −3V).

OPTIONAL CAPACITOR SELECTION

If an additional capacitor is going to be used in conjunction with the internal 100pF capacitor it must have a low dielectric absorption. Dielectric absorption is just that; it is the charge absorbed into the dielectric that is not immediately added to or removed from the capacitor when rapidly charged or discharged. The capacitor with dielectric absorption is modeled in Figure 14.

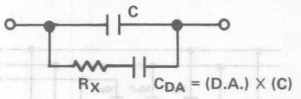

Figure 14. Capacitor Model with Dielectric Absorption

If the capacitor is charged slowly, C_{DA} will eventually charge to the same value as C. But unfortunately, good dielectrics have very high resistances, so while C_{DA} may be small, R_X is large and the time constant R_X C_{DA} typically runs into the millisecond range. In fast-charge, fast-discharge situations the effect of dielectric absorption resembles "memory". In a data acquisition system where many channels with widely varying data are being sampled the effect is to have an ever changing offset which appears as a very nonlinear sample-to-hold offset since the difference between the voltage being measured and the voltage previously measured determines the fraction by which the dielectric absorption figure is multiplied. It is impossible to readily correct for this error source. The only solution is to use a capacitor with dielectric absorption less than the maximum tolerable error. Capacitor types such as polystyrene, polypropylene or Teflon are recommended.

GROUNDING

Many data-acquisition components have two or more ground pins which are not connected together within the device. These "grounds" are usually referred to as the Logic Power Return, Analog Common (Analog Power Return), and Analog Signal Ground. These grounds must be tied together at one point, usually at the system power-supply ground. Ideally, a single solid ground would be desirable. However, since current flows through the ground wires and etch stripes of the circuit cards, and since these paths have resistance and inductance, hundreds of millivolts can be generated between the system ground point and the ground pin of the AD585. Separate ground returns should be provided to minimize the current flow in the path from sensitive points to the system ground point. In this way supply currents and logic-gate return currents are not summed into the same return path as analog signals where they would cause measurement errors.

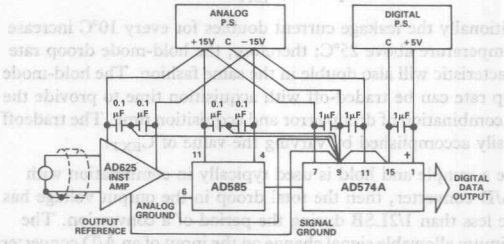

Figure 15. Basic Grounding Practice

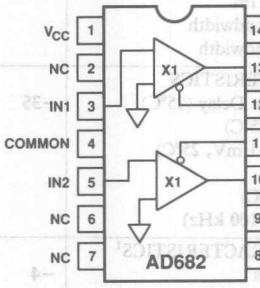

Two-Channel 700 ns Sample-and-Hold Amplifier

AD682*

FEATURES

- Two Matched Sample-and-Hold Amplifiers
- Fully Specified and Tested Hold Mode Distortion
- Acquisition Time to 0.01%: 700 ns Maximum
- Independent Inputs, Outputs and Control Pins
- Low Power Dissipation: 190 mW
- Low Droop Rate: 0.01 μV/μs
- Total Harmonic Distortion: −80 dB Maximum
- Aperture Jitter: 75 ps Maximum
- Internal Hold Capacitors
- Self-Correcting Architecture
- MIL-STD-883 Compliant Versions Available

FUNCTIONAL BLOCK DIAGRAM

PRODUCT DESCRIPTION

The AD682 is a two-channel high speed monolithic sample-and-hold amplifier (SHA). The AD682 guarantees a maximum acquisition time of 700 ns to 0.01% over temperature. Interchannel characteristics are fully specified and tested. The AD682 is also specified and tested for hold mode total harmonic distortion and hold mode signal-to-noise and distortion. The AD682 is configured as two independent unity gain amplifiers. The AD682 uses a self-correcting architecture that minimizes hold mode errors and insures accuracy over temperature. The AD682 is self-contained and requires no external components or adjustments.

The AD682 is ideal for systems demanding interchannel and hold mode characteristic requirements, such as in data acquisition systems and in-phase (I) and quadrature (Q) modulated systems. The independent inputs, outputs and controls allow maximum user configuration flexibility. The AD682 is ideal for 12- and 14-bit high speed analog-to-digital converters.

The AD682 is manufactured on a BiMOS process which merges high performance bipolar circuitry with low power CMOS to provide an accurate, high speed, low power SHA.

The AD682 is specified for three temperature ranges. The J grade device is specified for operation from 0°C to 70°C, the A grade from −40°C to +85°C and the S grade from −55°C to +125°C. The J and A grades are available in 14-pin plastic DIPs. The S grade is available in a 14-pin cerdip package.

PRODUCT HIGHLIGHTS

1. Fast acquisition time (700 ns) and low aperture jitter (75 ps) make the AD682 the best choice for multiple channel data acquisition systems.
2. Monolithic construction insures excellent interchannel matching, while testing guarantees the fully specified performance.
3. Independent inputs, outputs and sample-and-hold controls allow user flexibility.
4. Low droop (0.01 μV/μs) and internally compensated hold mode error results in superior system accuracy.
5. Fully specified and tested hold mode distortion and signal-to-noise and distortion guarantees the AD682's performance in sampled data systems.
6. The AD682's fast settling time and low output impedance make it ideal for driving high speed analog-to-digital converters such as the AD578, AD674B, AD774B, AD7572 and the AD7672.
7. The AD682 is available in versions compliant with MIL-STD-883. Refer to the Analog Devices Military Products Databook or current AD682/883B data sheet for detailed specifications.

*Protected by Patent Number 4,962,325.

Supply Current vs. Temperature

Supply Current vs. Supply Voltage

Acquisition Time (to 0.01%) vs. Input Step Size

DEFINITIONS OF SPECIFICATIONS

Acquisition Time – The length of time that the SHA must remain in the sample mode in order to acquire a full scale input step to a given level of accuracy.

Small Signal Bandwidth – The frequency at which the held output amplitude is 3 dB below the input amplitude, under an input condition of a 100 mV p–p sine wave.

Full Power Bandwidth – The frequency at which the held output amplitude is 3 dB below the input amplitude, under an input condition of a 10 V p–p sine wave.

Effective Aperture Delay – The difference between the switch delay and the analog delay of the SHA channel. A negative number indicates that the analog portion of the overall delay is greater than the switch portion. This effective delay represents the point in time, relative to the hold command, that the input signal will be sampled.

Aperture Jitter – The variations in delay for successive samples. Aperture jitter puts an upper limit on the maximum frequency that can be accurately sampled.

Hold Settling Time – The time required for the output to settle to within a specified level of accuracy of its final held value after the hold command has been given.

Droop Rate – The drift in output voltage while in the hold mode.

Feedthrough – The attenuated version of a changing input signal that appears at the output when the SHA is in the hold mode.

Hold Mode Offset – The difference between the input signal and the held output. This offset term applies only in the hold mode and includes the error caused by charge injection and all other internal offsets. It is specified for an input of 0 V.

Tracking Mode Offset – The difference between the input and output signals when the SHA is in the track mode.

Nonlinearity – The deviation from a straight line on a plot of input vs. (held) output as referenced to a straight line drawn between end points, over an input range of –5 V and +5 V.

Gain Error – Deviation from a gain of +1 on the transfer function of input vs. held output.

Interchannel Isolation – The level of crosstalk between adjacent channels while in the sample (track) mode with a full-scale 100 kHz input signal.

Interchannel Aperture Offset – The variation in aperture time between the two channels for a simultaneous hold command.

Interchannel Offset – The difference in hold mode offset between the two SHA channels.

Power Supply Rejection Ratio – A measure of change in the held output voltage for a specified change in the positive or negative supply.

Sampled DC Uncertainty – The internal rms SHA noise that is sampled onto the hold capacitor.

Hold Mode Noise – The rms noise at the output of the SHA while in the hold mode, specified over a given bandwidth.

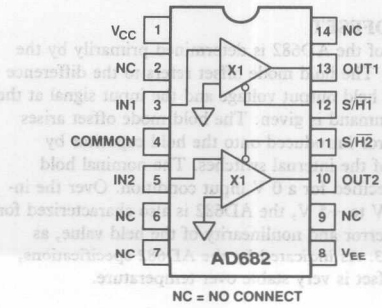
Total Output Noise – The total rms noise that is seen at the output of the SHA while in the hold mode. It is the rms summation of the sampled dc uncertainty and the hold mode noise.

Output Drive Current – The maximum current the SHA can source (or sink) while maintaining a change in hold mode offset of less than 2.5 mV.

Signal-to-Noise and Distortion (S/N+D) Ratio – S/N+D is the ratio of the rms value of the measured input signal to the rms sum of all other spectral components below the Nyquist frequency, including harmonics but excluding dc.

Total Harmonic Distortion (THD) – THD is the ratio of the rms sum of the first six harmonic components to the rms value of the measured input signal.

Intermodulation Distortion (IMD) – With inputs consisting of sine waves at two frequencies, fa and fb, any device with nonlinearities will create distortion products, of order (m+n), at sum and difference frequency of mfa±nfb, where m, n = 0, 1, 2, 3 . . . . Intermodulation terms are those for which m or n is not equal to zero. For example, the second order terms are (fa+fb) and (fa−fb), and the third order terms are (2fa+fb), (2fa−fb), (fa+2fb) and (fa−2fb). The IMD products are expressed as the decibel ratio of the rms sum of the measured input signals to the rms sum of the distortion terms. The two signals are of equal amplitude, and peak value of their sums is −0.5 dB from full scale. The IMD products are normalized to a 0 dB input signal.



FUNCTIONAL DESCRIPTION

The AD682 is a complete dual sample-and-hold amplifier that provides high speed sampling to 12-bit accuracy in less than 700 ns.

The AD682 is completely self-contained, including on-chip hold capacitors, and requires no external components or adjustments to perform the sampling function. Each SHA channel can operate independently, having its own input, output and sample/hold command. Both inputs and outputs are treated as single-ended signals, referred to common.

The AD682 utilizes a proprietary circuit design which includes a self-correcting architecture. This sample-and-hold circuit corrects for internal errors after the hold command has been given, by compensating for amplifier gain and offset errors, and charge injection errors. Due to the nature of the design, the SHA output in the sample mode is not intended to provide an accurate representation of the input. However, in hold mode, the internal circuitry is reconfigured to produce an accurately held version of the input signal. Below is a block diagram of the AD682.

FUNCTIONAL BLOCK DIAGRAM

NC = NO CONNECT

DYNAMIC PERFORMANCE

The AD682 is compatible with 12-bit A-to-D converters in terms of both accuracy and speed. The fast acquisition time, fast hold settling time and good output drive capability allow the AD682 to be used with high speed, high resolution A-to-D converters like the AD674B, AD774B and AD7672. The AD682's fast acquisition time provides high throughput rates for multichannel data acquisition systems. Typically, the sample and hold can acquire a 10 V step in less than 600 ns. Figure 1 shows the settling accuracy as a function of acquisition time.

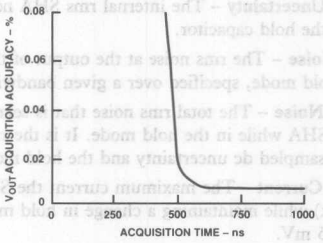


Figure 1. V_{OUT} Settling vs. Acquisition Time

The hold settling determines the required time, after the hold command is given, for the output to settle to its final specified accuracy. The typical settling behavior of the AD682 is shown in Figure 2. The settling time of the AD682 is sufficiently fast to allow the SHA, in most cases, to directly drive an A-to-D converter without the need for an added "start convert" delay.

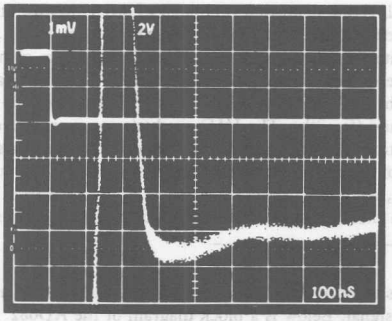

Figure 2. Typical AD682 Hold Mode

HOLD MODE OFFSET

The dc accuracy of the AD682 is determined primarily by the hold mode offset. The hold mode offset refers to the difference between the final held output voltage and the input signal at the time the hold command is given. The hold mode offset arises from a voltage error introduced onto the hold capacitor by charge injection of the internal switches. The nominal hold mode offset is specified for a 0 V input condition. Over the input range of −5 V to +5 V, the AD682 is also characterized for an effective gain error and nonlinearity of the held value, as shown in Figure 3. As indicated by the AD682 specifications, the hold mode offset is very stable over temperature.

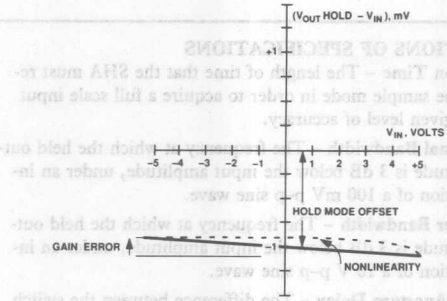

Figure 3. Hold Mode Offset, Gain Error and Nonlinearity

For applications where it is important to obtain zero offset, the hold mode offset may be nulled externally at the input to the A-to-D converter. Adjustment of the offset may be accomplished through the A-to-D itself or by an external amplifier with offset nulling capability (e.g., AD711). The offset will change less than 0.5 mV over the specified temperature range.

SUPPLY DECOUPLING AND GROUNDING CONSIDERATIONS

As with any high speed, high resolution data acquisition system, the power supplies should be well regulated and free from excessive high frequency noise (ripple). The supply connection to the AD682 should also be capable of delivering transient currents to the device. To achieve the specified accuracy and dynamic performance, decoupling capacitors must be placed directly at both the positive and negative supply pins to common. Ceramic type 0.1 μF capacitors should be connected from V_{CC} and V_{EE} to common.

The AD682 does not provide separate analog and digital ground leads as is the case with most A-to-D converters. The common pin is the single ground terminal for the device. It is the reference point for the sampled input voltage and the held output voltage and also the digital ground return path. The common pin should be connected to the reference (analog) ground of the A-to-D converter with a separate ground lead. Since the analog and digital grounds in the AD682 are connected internally, the common pin should also be connected to the digital ground, which is usually tied to analog common at the A-to-D converter. Figure 4 illustrates the recommended decoupling and grounding practice.

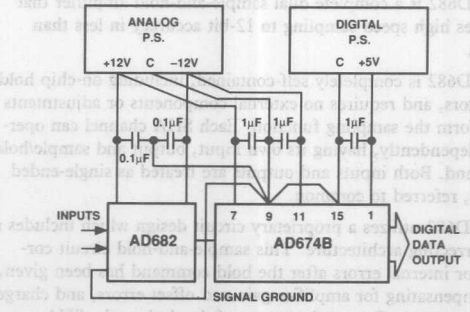

Figure 4. Basic Grounding and Decoupling Diagram

NOISE CHARACTERISTICS

Designers of data conversion circuits must also consider the effect of noise sources on the accuracy of the data acquisition system. A sample-and-hold amplifier that precedes the A-to-D converter introduces some noise and represents another source of uncertainty in the conversion process. The noise from the AD682 is specified as the total output noise, which includes both the sampled wideband noise of the SHA in addition to the band limited output noise. The total output noise is the rms sum of the sampled dc uncertainty and the hold mode noise. A plot of the total output noise vs. the equivalent input bandwidth of the converter being used is given in Figure 5.

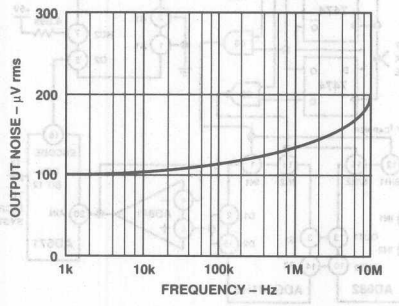

Figure 5. RMS Noise vs. Input Bandwidth of ADC

DRIVING THE ANALOG INPUTS

For best performance, it is important to drive the AD682 analog input from a low impedance signal source. This enhances the sampling accuracy by minimizing the analog and digital crosstalk. Signals which come from higher impedance sources (e.g., over 5 kΩ) will have a relatively higher level of crosstalk. For applications where signals have high source impedance, an operational amplifier buffer in front of the AD682 is required. The AD712 (precision BiFET op amp) is recommended for these applications.

HIGH FREQUENCY SAMPLING

Aperture jitter and distortion are the primary factors which limit frequency domain performance of a sample-and-hold amplifier. Aperture jitter modulates the phase of the hold command and produces an effective noise on the sampled analog input. The magnitude of the jitter induced noise is directly related to the frequency of the input signal.

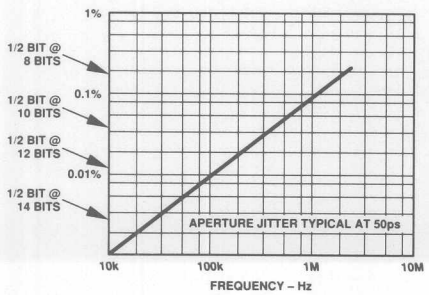

Figure 6. Error Magnitude vs. Frequency

A graph showing the magnitude of the jitter induced error vs. frequency of the input signal is given in Figure 6.

The accuracy in sampling high frequency signals is also constrained by the distortion and noise created by the sample-and-hold. The level of distortion increases with frequency and reduces the "effective number of bits" of the conversion.

Measurements of Figures 7 and 8 were made using a 14-bit A-to-D converter with V_{IN} = 10 V p–p and a sample frequency of 100 kSPS.

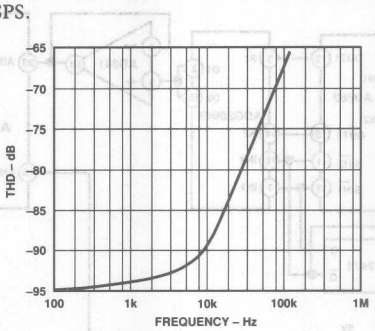

Figure 7. Total Harmonic Distortion vs. Frequency

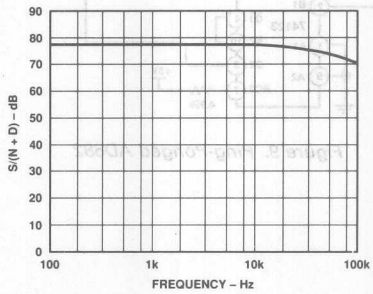

Figure 8. Signal/(Noise and Distortion) vs. Frequency

THE AD682 IN A PING-PONG ARRANGEMENT

In a ping-pong arrangement two sample-and-hold amplifiers are connected to the same analog input source. While one channel is sampling the analog input, the other is in the hold mode. Depending upon the ADC conversion time, a ping-pong circuit can increase data throughput rates by as much as 100%. The AD682's excellent interchannel aperture delay, gain and offset errors make it ideal to use in a ping-pong arrangement.

Figure 9 shows the AD682 in a ping-pong arrangement with the AD671 12-bit, 500 ns A/D converter. A high speed switch (ADG201HS) directs the appropriate AD682 output to the AD671. In this system the data throughput rate is increased by up to 80% as compared to a system using only one channel of the AD682.

THE AD682 FOR IN-PHASE (I) AND QUADRATURE (Q) DEMODULATION

The AD682 can be used to demodulate digital data that has been I and Q modulated. Using two SHAs for the signal acqui-

sition allows the use of slower and lower cost SHAs and A/D converters as compared to a system using one SHA.

Figure 10 shows the AD682 being used as a I and Q demodulator. If the carrier frequency is represented by f and w = 2 πf, the incoming signal can be represented by s(t) = I(n) × cos(wt) + Q(n) × sin(wt), where I(n) and Q(n) (the nth I– Q pair sent) only take on discrete values and must stay constant for at least one carrier period (2 π/w).

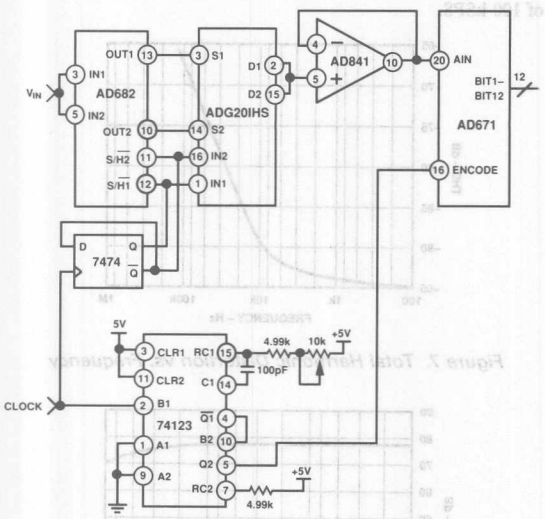

Figure 9. Ping-Ponged AD682

The clock source from which the AD682's control signals are derived must be coherent with the input signal carrier. To recover I(n), s(t) must be sampled when the in-phase carrier component is 1 and the quadrature component is 0 (when t is integer multiples of 2 π/W). Similarly to recover Q(n) s(t) must be sampled when the in-phase carrier component is 0 and the quadrature component is 1 (when t is integer multiples of 2 π/w + π/2).

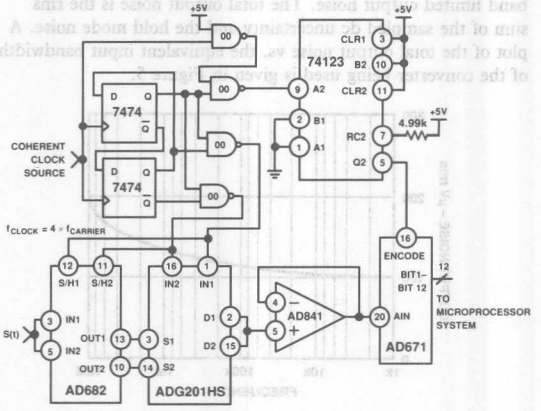

Figure 10. The AD682 Used for I and Q Demodulation

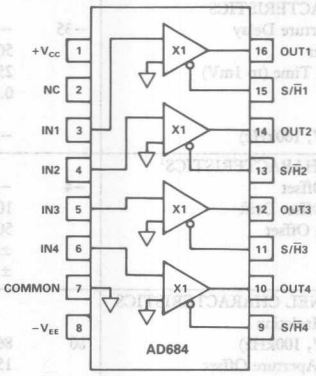

Four-Channel Sample-and-Hold Amplifier

AD684*

FEATURES

Four Matched Sample-and-Hold Amplifiers
Independent Inputs, Outputs and Control Pins
500ns Hold Mode Settling
1μs Maximum Acquisition Time to 0.01%
Low Droop Rate: 0.01μV/μs
Internal Hold Capacitors
75ps Maximum Aperture Jitter
Low Power Dissipation: 430mW
0.3″ Skinny DIP Package
MIL-STD-883 Compliant Versions Available

FUNCTIONAL BLOCK DIAGRAM

PRODUCT DESCRIPTION

The AD684 is a monolithic quad sample-and-hold amplifier (SHA). It features four complete sampling channels, each controlled by an independent hold command. Each SHA is complete with an internal hold capacitor. The high accuracy SHA channels are self-contained and require no external components or adjustments. The AD684 is manufactured on a BiMOS process which provides a merger of high performance bipolar circuitry and low power CMOS logic.

The AD684 is ideal for high performance, multichannel data acquisition systems. Each SHA channel can acquire a signal in less than 1μs and retain the held value with a droop rate of less than 0.01μV/μs. Excellent linearity and ac performance make the AD684 an ideal front end for high speed 12- and 14-bit ADCs.

The AD684 has a self-correcting architecture that minimizes hold mode errors and insures accuracy over temperature. Each channel of the AD684 is capable of sourcing 5mA and incorporates output short circuit protection.

The AD684 is specified for three temperature ranges. The J grade device is specified for operation from 0 to 70°C, the A grade from −40°C to +85°C and the S grade from −55°C to +125°C.

PRODUCT HIGHLIGHTS

1. Fast acquisition time (1μs) and low aperture jitter (75ps) make the AD684 the best choice for multiple channel data acquisition systems.
2. Monolithic construction insures excellent interchannel matching in terms of timing and accuracy, as well as high reliability.
3. Independent inputs, outputs and sample-and-hold controls allow user flexibility in system architecture.
4. Low droop (0.01μV/μs) and internally compensated hold mode error results in superior system accuracy.
5. The AD684's fast settling time and low output impedance make it ideal for driving high speed analog to digital converters such as the AD578, AD674, AD7572 and the AD7672.
6. The AD684 is available in versions compliant with MIL-STD-883. Refer to the Analog Devices *Military Products Databook* or current AD684/883B data sheet for detailed specifications.

NOTES

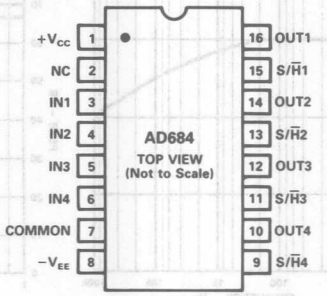
[1]Specified and tested over an input range of ±5V.

[2]Maximum current the AD684 can source (or sink). Testing guarantees that the accuracy of the held signal remains within 2.5mV of its initial value.

[3]The output is protected for a short circuit to common, V_{CC} and V_{EE}.

[4]V_{CC} and V_{EE} at nominal voltage levels.

Specifications shown in **boldface** are tested on all production units at final electrical test. Results from those tests are used to calculate outgoing quality levels. All min and max specifications are guaranteed, although only those shown in boldface are tested on all production units.



Specifications subject to change without notice.

ABSOLUTE MAXIMUM RATINGS*

Spec	With Respect to	Min	Max	Unit
V_{CC}	Common	−0.3	+15	V
V_{EE}	Common	−15	+0.3	V
Control Inputs	Common	−0.5	+7	V
Analog Inputs	Common	−12	+12	V
Output Short Circuit to Ground, V_{CC}, or V_{EE}		Indefinite		
Max Junction Temperature			+175	°C
Storage		−65	+150	°C
Lead Temperature (10sec max)			+300	°C
Power Dissipation			640	mW

*Stresses above those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. This is a stress rating only and functional operation of the device at these or any other conditions above those indicated in the operational section of this specification is not implied.

PIN CONFIGURATION

NC = NO CONNECT

4

CAUTION

ESD (electrostatic discharge) sensitive device. The digital control inputs are diode protected; however, permanent damage may occur on unconnected devices subject to high energy electrostatic fields. Unused devices must be stored in conductive foam or shunts.

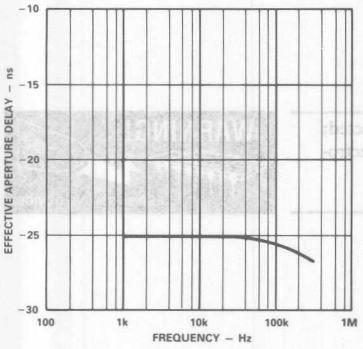
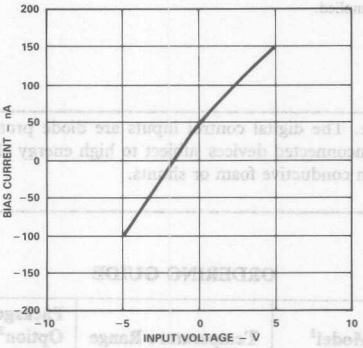
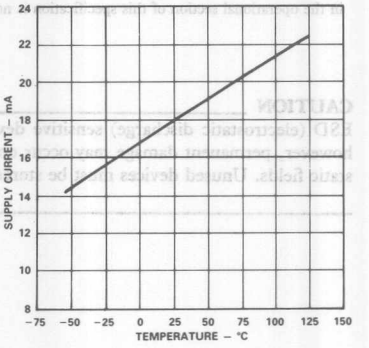
AD684 — Typical Characteristics



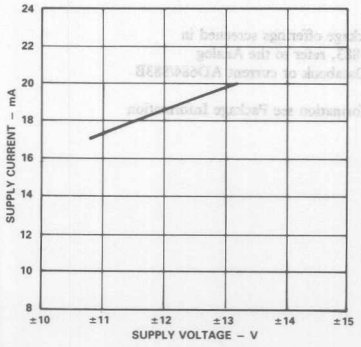
Interchannel Isolation vs. Frequency



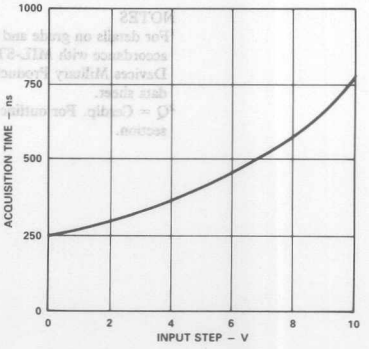
Power Supply Rejection Ratio vs. Frequency



Droop Rate vs. Temperature, V_{IN} = 0V



Effective Aperture Delay vs. Frequency



Bias Current vs. Input Voltage

Supply Current vs. Temperature

Supply Current vs. Supply Voltage

Acquisition Time (to 0.01%) vs. Input Step Size

DEFINITIONS OF SPECIFICATIONS

Acquisition Time — The length of time that the SHA must remain in the sample mode in order to acquire a full scale input step to a given level of accuracy.

Small Signal Bandwidth — The frequency at which the held output amplitude is 3dB below the input amplitude, under an input condition of a 100mV p-p sine wave.

Full Power Bandwidth — The frequency at which the held output amplitude is 3dB below the input amplitude, under an input condition of a 10V p-p sine wave.

Effective Aperture Delay — The difference between the switch delay and the analog delay of the SHA channel. A negative number indicates that the analog portion of the overall delay is greater than the switch portion. This effective delay represents the point in time, relative to the hold command, that the input signal will be sampled.

Aperture Jitter — The variations in aperture delay for successive samples. Aperture jitter puts an upper limit on the maximum frequency that can be accurately sampled.

Hold Settling Time — The time required for the output to settle to within a specified level of accuracy of its final held value after the hold command has been given.

Droop Rate — The drift in output voltage while in the hold mode.

Feedthrough — The attenuated version of a changing input signal that appears at the output when the SHA is in the hold mode.

Hold Mode Offset — The difference between the input signal and the held output. This offset term applies only in the hold mode and includes the error caused by charge injection and all other internal offsets. It is specified for an input of 0V.

Tracking Mode Offset — The difference between the input and output signals when the SHA is in the track mode.

Nonlinearity — The deviation from a straight line on a plot of input vs. (held) output as referenced to a straight line drawn between endpoints, over an input range of −5V and +5V.

Gain Error — Deviation from a gain of +1 on the transfer function of input vs. held output.

Interchannel Isolation — The level of crosstalk between adjacent channels while in the sample (track) mode with a full scale 100kHz input signal.

Interchannel Aperture Offset — The variation in aperture time between the four channels for a simultaneous hold command.

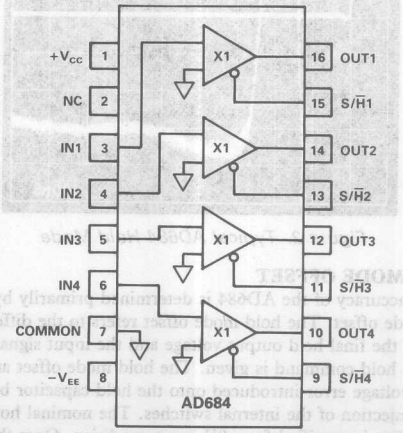
Differential Offset — The difference in hold mode offset between the four SHA channels.

Power Supply Rejection Ratio — A measure of change in the held output voltage for a specified change in the positive or negative supply.

Sampled dc Uncertainty — The internal rms SHA noise that is sampled onto the hold capacitor.

Hold Mode Noise — The rms noise at the output of the SHA while in the hold mode, specified over a given bandwidth.

Total Output Noise — The total rms noise that is seen at the output of the SHA while in the hold mode. It is the rms summation of the sampled dc uncertainty and the hold mode noise.



Output Drive Current — The maximum current the SHA can source (or sink) while maintaining a change in hold mode offset of less than 2.5mV.

FUNCTIONAL DESCRIPTION

The AD684 is a complete quad sample-and hold amplifier that provides high speed sampling to 12-bit accuracy in less than 1μs.

The AD684 is completely self-contained, including on-chip hold capacitors, and requires no external components or adjustments to perform the sampling function. Each SHA channel can operate independently, having its own input, output and sample/hold command. Both inputs and outputs are treated as single ended signals, referred to common.

The AD684 utilizes a proprietary circuit design which includes a self-correcting architecture. This sample-and-hold circuit corrects for internal errors after the hold command has been given, by compensating for amplifier gain and offset errors, and charge injection errors. Due to the nature of the design, the SHA output in the sample mode is not intended to provide an accurate representation of the input. However, in hold mode, the internal circuitry is reconfigured to produce an accurately held version of the input signal. To the right is a block diagram of the AD684.

Functional Block Diagram

DYNAMIC PERFORMANCE

The AD684 is compatible with 12-bit A-to-D converters in terms of both accuracy and speed. The fast acquisition time, fast hold settling time and good output drive capability allow the AD684 to be used with high speed, high resolution A-to-D converters like the AD674 and AD7672. The AD684's fast acquisition time provides high throughput rates for multichannel data acquisition systems. Typically, the sample and hold can acquire a 10V step in less than 750ns. Figure 1 shows the settling accuracy as a function of acquisition time.

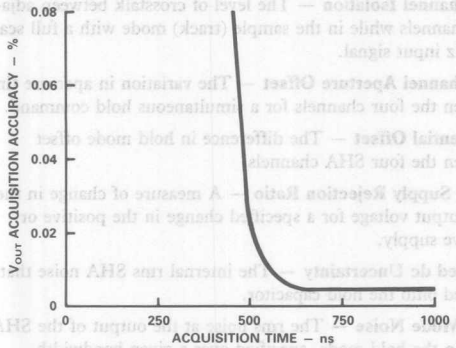


Figure 1. V_{OUT} Settling vs. Acquisition Time

The hold settling determines the required time, after the hold command is given, for the output to settle to its final specified accuracy. The typical settling behavior of the AD684 is shown in Figure 2. The settling time of the AD684 is sufficiently fast to allow the SHA, in most cases, to directly drive an A-to-D converter without the need for an added "start convert" delay.

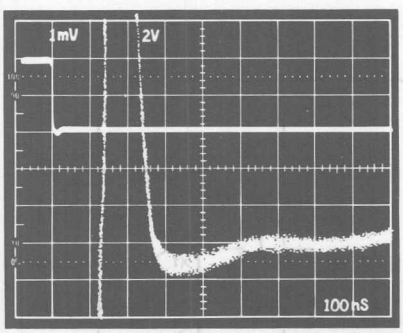

Figure 2. Typical AD684 Hold Mode

HOLD MODE OFFSET

The dc accuracy of the AD684 is determined primarily by the hold mode offset. The hold mode offset refers to the difference between the final held output voltage and the input signal at the time the hold command is given. The hold mode offset arises from a voltage error introduced onto the hold capacitor by charge injection of the internal switches. The nominal hold mode offset is specified for a 0V input condition. Over the input range of −5V to +5V, the AD684 is also characterized for an effective gain error and nonlinearity of the held value, as shown in Figure 3. As indicated by the AD684 specifications, the hold mode offset is very well matched between channels and stable over temperature.

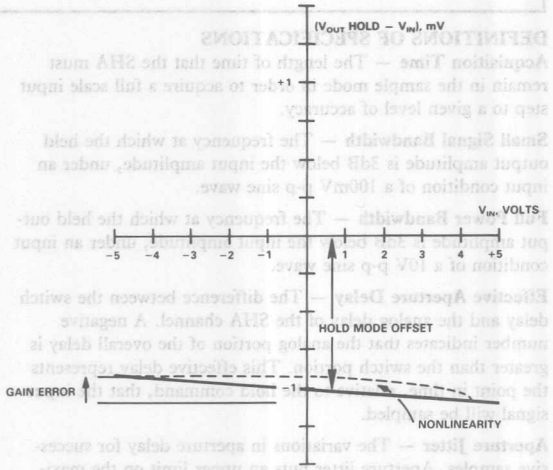

Figure 3. Hold Mode Offset, Gain Error and Nonlinearity

For applications where it is important to obtain zero offset, the hold mode offset may be nulled externally at the input to the A-to-D converter. Adjustment of the offset may be accomplished through the A-to-D itself or by an external amplifier with offset nulling capability (e.g., AD711). Only a single adjustment of the offset is necessary for the four SHA channels as a result of the excellent matching among them. The offset will change less than 0.5mV over the specified temperature range.

SUPPLY DECOUPLING AND GROUNDING CONSIDERATIONS

As with any high speed, high resolution data acquisition system, the power supplies should be well regulated and free from excessive high frequency noise (ripple). The supply connection to the AD684 should also be capable of delivering transient currents to the device. To achieve the specified accuracy and dynamic performance, decoupling capacitors must be placed directly at both the positive and negative supply pins to common. Ceramic type 0.1μF capacitors should be connected from V_{CC} and V_{EE} to common.

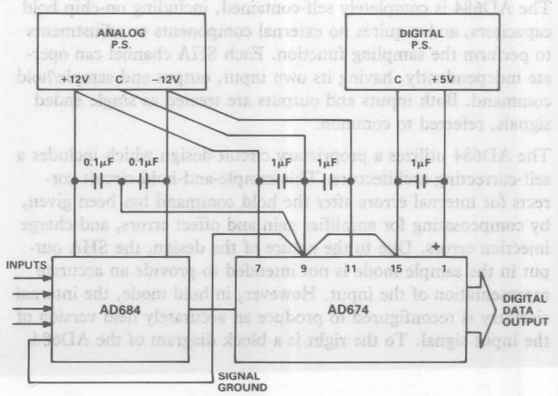

Figure 4. Basic Grounding and Decoupling Diagram

The AD684 does not provide separate analog and digital ground leads as is the case with most A-to-D converters. The common pin is the single ground terminal for the device. It is the reference point for the sampled input voltage and the held output voltage and also the digital ground return path. The common pin should be connected to the reference (analog) ground of the A-to-D converter with a separate ground lead. Since the analog and digital grounds in the 684 are connected internally, the common pin should also be connected to the digital ground, which is usually tied to analog common at the A-to-D converter. Figure 4 illustrates the recommended decoupling and grounding practice.

NOISE CHARACTERISTICS

Designers of data conversion circuits must also consider the effect of noise sources on the accuracy for the data acquisition system. A sample-and-hold amplifier that precedes the A-to-D converter introduces some noise and represents another source of uncertainty in the conversion process. The noise from the AD684 is specified as the total output noise, which includes both the sampled wideband noise of the SHA in addition to the band limited output noise. The total output noise is the rms sum of the sampled dc uncertainty and the hold mode noise. A plot of the total output noise vs. the equivalent input bandwidth of the converter being used is given in Figure 5.

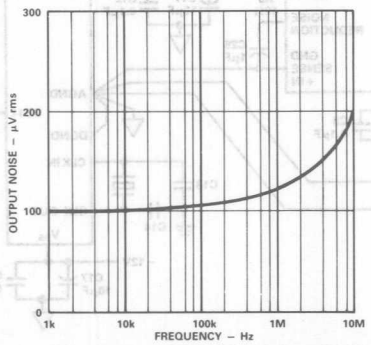

Figure 5. RMS Noise vs. Input Bandwidth of ADC

DRIVING THE ANALOG INPUTS

For best performance, it is important to drive the AD684 analog inputs from a low impedance signal source. This enhances the sampling accuracy by minimizing the analog and digital crosstalk. Signals which come from higher impedance sources (e.g., over 5k ohms) will have a relatively higher level of crosstalk. For applications where signals have high source impedance, an operational amplifier buffer in front of the AD684 is required. The AD713 (precision quad BiFET op amp) is recommended for these applications.

HIGH FREQUENCY SAMPLING

Aperture jitter and distortion are the primary factors which limit frequency domain performance of a sample-and-hold amplifier. Aperture jitter modulates the phase of the hold command and produces an effective noise on the sampled analog input. The magnitude of the jitter induced noise is directly related to the frequency of the input signal.

A graph showing the magnitude of the jitter induced error vs. frequency of the input signal is given in Figure 6.

The accuracy in sampling high frequency signals is also constrained by the distortion and noise created by the sample-and-hold. The level of distortion increases with frequency and reduces the "effective number of bits" of the conversion.

Measurements of Figures 7 and 8 were made using a 14-bit A-to-D converter with $V_{IN} = 10V$ p-p and a sample frequency of 100kSPS.

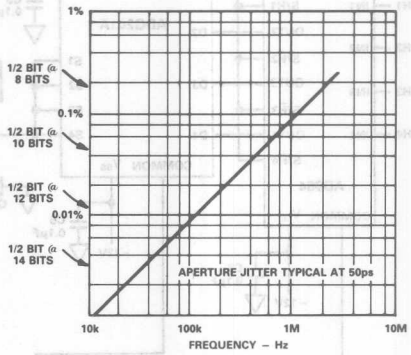

Figure 6. Error Magnitude vs. Frequency

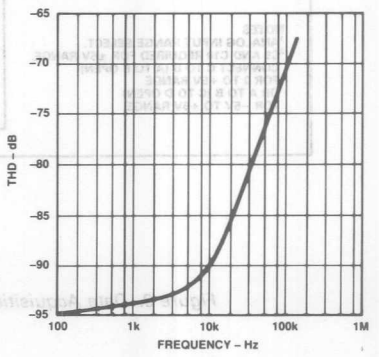

Figure 7. Total Harmonic Distortion vs. Frequency

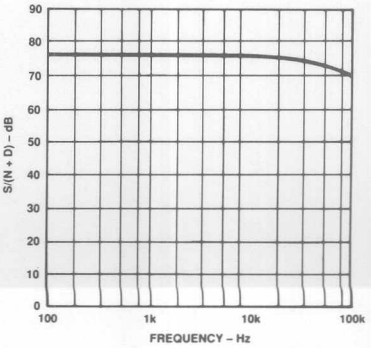

Figure 8. Signal/(Noise and Distortion) vs. Frequency

DATA ACQUISITION APPLICATIONS

Figure 9 shows a typical data acquisition circuit using the AD684 and the high speed 12-bit A-to-D converter, the AD7672. Four input signals are simultaneously sampled by the AD684 as the $\overline{HOLD}$ command is given. One of the four held outputs is selected by the ADG201, quad CMOS switch, and buffered by the AD711. The AD588 provides the reference voltage with switches A–B and C–D selecting a −5V to +5V or 0 to +5V input range.

PRODUCT DESCRIPTION

The AD781 is a high speed monolithic sample-and-hold amplifier (SHA). The AD781 guarantees a maximum acquisition time of 700 ns to 0.01% over temperature. The AD781 is specified and tested for hold mode total harmonic distortion and hold mode signal-to-noise and distortion. The AD781 is configured as a unity gain amplifier and uses a self-correcting architecture that minimizes hold mode errors and insures accuracy over temperature. The AD781 is self-contained and requires no external components or adjustments.

The low power dissipation, 8-pin mini-DIP package and completeness make the AD781 ideal for highly compact board layouts. The AD781 will acquire a full-scale input in less than 700 ns and retain the held value with a droop rate of 0.01 μV/μs. Excellent linearity and hold mode dc and dynamic performance make the AD781 ideal for 12- and 14-bit high speed analog-to-digital converters.

The AD781 is manufactured on Analog Devices' BiMOS process which merges high performance, low noise bipolar circuitry with low power CMOS to provide an accurate, high speed, low power SHA.

The AD781 is specified for three temperature ranges. The J grade device is specified for operation from 0°C to 70°C, the A grade from −40°C to +85°C and the S grade from −55°C to +125°C. The J and A grades are available in 8-pin plastic DIP packages. The S grade is available in an 8-pin cerdip package.

***Protected by U.S. Patent No. 4,962,325.**

PRODUCT HIGHLIGHTS

1. Fast acquisition time (700 ns), low aperture jitter (75 ps) and fully specified hold mode distortion make the AD781 an ideal SHA for sampling systems.
2. Low droop (0.01 μV/μs) and internally compensated hold mode error results in superior system accuracy.
3. Low power (95 mW typical), complete functionality and small size make the AD781 an ideal choice for a variety of high performance, low power applications.
4. The AD781 requires no external components or adjustments.
5. Excellent choice as a front-end SHA for high speed analog-to-digital converters such as the AD671, AD7586, AD674B, AD774B, AD7572 and AD7672.
6. Fully specified and tested hold mode distortion guarantees the performance of the SHA in sampled data systems.
7. The AD781 is available in versions compliant with MIL-STD-883. Refer to the Analog Devices Military Products Databook or current AD781/883B data sheet for detailed specifications.

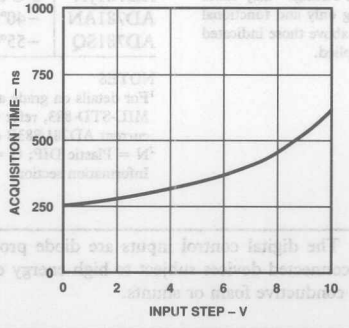
Effective Aperture Delay vs. Frequency



Bias Current vs. Input Voltage

Supply Current vs. Temperature

Supply Current vs. Supply Voltage

Acquisition Time (to 0.01%) vs. Input Step Size

DEFINITIONS OF SPECIFICATIONS

Acquisition Time—The length of time that the SHA must remain in the sample mode in order to acquire a full-scale input step to a given level of accuracy.

Small Signal Bandwidth—The frequency at which the held output amplitude is 3 dB below the input amplitude, under an input condition of a 100 mV p–p sine wave.

Full Power Bandwidth—The frequency at which the held output amplitude is 3 dB below the input amplitude, under an input condition of a 10 V p–p sine wave.

Effective Aperture Delay—The difference between the switch delay and the analog delay of the SHA channel. A negative number indicates that the analog portion of the overall delay is greater than the switch portion. This effective delay represents the point in time, relative to the hold command, that the input signal will be sampled.

Aperture Jitter—The variations in aperture delay for successive samples. Aperture jitter puts an upper limit on the maximum frequency that can be accurately sampled.

Hold Settling Time—The time required for the output to settle to within a specified level of accuracy of its final held value after the hold command has been given.

Droop Rate—The drift in output voltage while in the hold mode.

Feedthrough—The attenuated version of a changing input signal that appears at the output when the SHA is in the hold mode.

Hold Mode Offset—The difference between the input signal and the held output. This offset term applies only in the hold mode and includes the error caused by charge injection and all other internal offsets. It is specified for an input of 0 V.

Tracking Mode Offset—The difference between the input and output signals when the SHA is in the track mode.

Nonlinearity—The deviation from a straight line on a plot of input vs. (held) output as referenced to a straight line drawn between endpoints, over an input range of −5 V and +5 V.

Gain Error—Deviation from a gain of +1 on the transfer function of input vs. held output.

Power Supply Rejection Ratio—A measure of change in the held output voltage for a specified change in the positive or negative supply.

Sampled DC Uncertainty—The internal rms SHA noise that is sampled onto the hold capacitor.

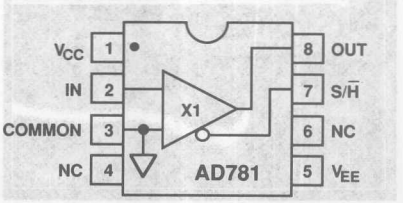
Hold Mode Noise—The rms noise at the output of the SHA while in the hold mode, specified over a given bandwidth.

Total Output Noise—The total rms noise that is seen at the output of the SHA while in the hold mode. It is the rms summation of the sampled dc uncertainty and the hold mode noise.

Output Drive Current—The maximum current the SHA can source (or sink) while maintaining a change in hold mode offset of less than 2.5 mV.

Signal-To-Noise and Distortion (S/N+D) Ratio—S/N+D is the ratio of the rms value of the measured input signal to the rms sum of all other spectral components below the Nyquist frequency, including harmonics but excluding dc. The value for S/N+D is expressed in decibels.

Total Harmonic Distortion (THD)—THD is the ratio of the rms sum of the first six harmonic components to the rms value of the measured input signal and is expressed as a percentage or in decibels.



Intermodulation Distortion (IMD)—With inputs consisting of sine waves at two frequencies, fa and fb, any device with nonlinearities will create distortion products, of order (m+n), at sum and difference frequency of mfa±nfb, where m, n = 0, 1, 2, 3 . . . . Intermodulation terms are those for which m or n is not equal to zero. For example, the second order terms are (fa+fb) and (fa−fb), and the third order terms are (2fa+fb), (2fa−fb), (fa+2fb) and (fa−2fb). The IMD products are expressed as the decibel ratio of the rms sum of the measured input signals to the rms sum of the distortion terms. The two signals are of equal amplitude, and peak value of their sums is −0.5 dB from full scale. The IMD products are normalized to a 0 dB input signal.

FUNCTIONAL DESCRIPTION

The AD781 is a complete sample-and-hold amplifier that provides high speed sampling to 12-bit accuracy in less than 700 ns.

The AD781 is completely self-contained, including an on-chip hold capacitor, and requires no external components or adjustments to perform the sampling function. Both input and output are treated as a single-ended signal, referred to common.

The AD781 utilizes a proprietary circuit design which includes a self-correcting architecture. This sample-and-hold circuit corrects for internal errors after the hold command has been given, by compensating for amplifier gain and offset errors, and charge injection errors. Due to the nature of the design, the SHA output in the sample mode is not intended to provide an accurate representation of the input. However, in hold mode, the internal circuitry is reconfigured to produce an accurately held version of the input signal. Below is a block diagram of the AD781.

Functional Block Diagram

DYNAMIC PERFORMANCE

The AD781 is compatible with 12-bit A-to-D converters in terms of both accuracy and speed. The fast acquisition time, fast hold settling time and good output drive capability allow the AD781 to be used with high speed, high resolution A-to-D converters like the AD674 and AD672. The AD781's fast acquisition time provides high throughput rates for multichannel data acquisition systems. Typically, the sample and hold can acquire a 10 V step in less than 600 ns. Figure 1 shows the settling accuracy as a function of acquisition time.

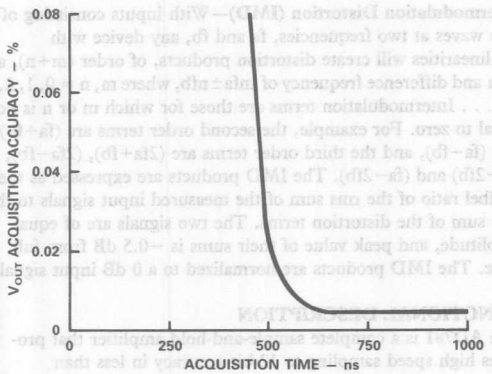


Figure 1. V_{OUT} Settling vs. Acquisition Time

The hold settling determines the required time, after the hold command is given, for the output to settle to its final specified accuracy. The typical settling behavior of the AD781 is shown in Figure 2. The settling time of the AD781 is sufficiently fast to allow the SHA, in most cases, to directly drive an A-to-D converter without the need for an added "start convert" delay.

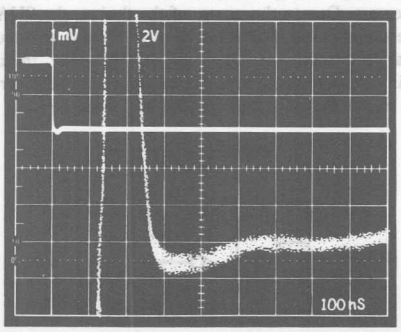

Figure 2. Typical AD781 Hold Mode

HOLD MODE OFFSET

The dc accuracy of the AD781 is determined primarily by the hold mode offset. The hold mode offset refers to the difference between the final held output voltage and the input signal at the time the hold command is given. The hold mode offset arises from a voltage error introduced onto the hold capacitor by charge injection of the internal switches. The nominal hold mode offset is specified for a 0 V input condition. Over the input range of −5 V to +5 V, the AD781 is also characterized for

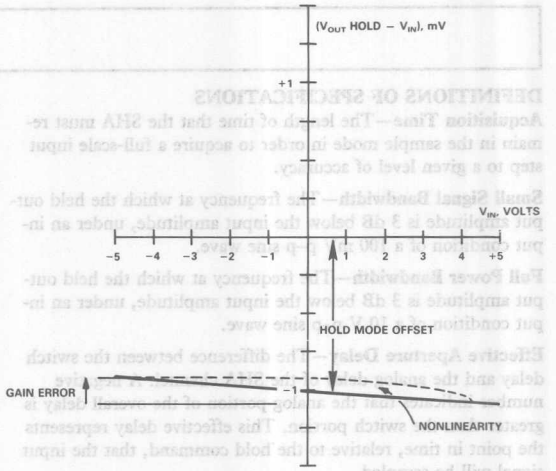

Figure 3. Hold Mode Offset, Gain Error and Nonlinearity

an effective gain error and nonlinearity of the held value, as shown in Figure 3. As indicated by the AD781 specifications, the hold mode offset is very stable over temperature.

For applications where it is important to obtain zero offset, the hold mode offset may be nulled externally at the input to the A-to-D converter. Adjustment of the offset may be accomplished through the A-to-D itself or by an external amplifier with offset nulling capability (e.g., AD711). The offset will change less than 0.5 mV over the specified temperature range.

SUPPLY DECOUPLING AND GROUNDING CONSIDERATIONS

As with any high speed, high resolution data acquisition system, the power supplies should be well regulated and free from excessive high frequency noise (ripple). The supply connection to the AD781 should also be capable of delivering transient currents to the device. To achieve the specified accuracy and dynamic performance, decoupling capacitors must be placed directly at both the positive and negative supply pins to common. Ceramic type 0.1 μF capacitors should be connected from V_{CC} and V_{EE} to common.

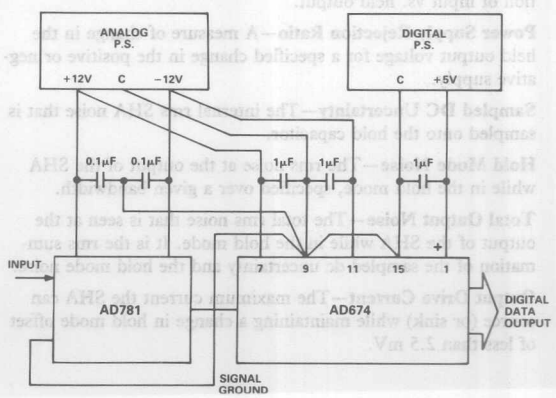

Figure 4. Basic Grounding and Decoupling Diagram

The AD781 does not provide separate analog and digital ground leads as is the case with most A-to-D converters. The common pin is the single ground terminal for the device. It is the reference point for the sampled input voltage and the held output voltage and also the digital ground return path. The common pin should be connected to the reference (analog) ground of the A-to-D converter with a separate ground lead. Since the analog and digital grounds in the AD781 are connected internally, the common pin should also be connected to the digital ground, which is usually tied to analog common at the A-to-D converter. Figure 4 illustrates the recommended decoupling and grounding practice.

NOISE CHARACTERISTICS

Designers of data conversion circuits must also consider the effect of noise sources on the accuracy of the data acquisition system. A sample-and-hold amplifier that precedes the A-to-D converter introduces some noise and represents another source of uncertainty in the conversion process. The noise from the AD781 is specified as the total output noise, which includes both the sampled wideband noise of the SHA in addition to the band limited output noise. The total output noise is the rms sum of the sampled dc uncertainty and the hold mode noise. A plot of the total output noise vs. the equivalent input bandwidth of the converter being used is given in Figure 5.

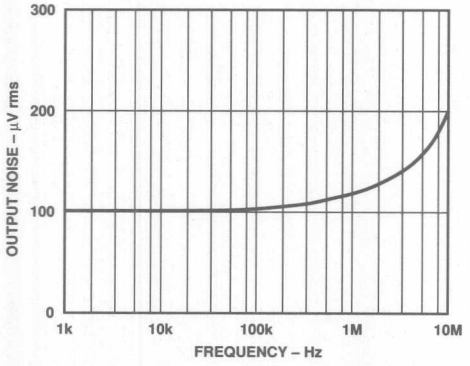

Figure 5. RMS Noise vs. Input Bandwidth of ADC

DRIVING THE ANALOG INPUTS

For best performance, it is important to drive the AD781 analog input from a low impedance signal source. This enhances the sampling accuracy by minimizing the analog and digital crosstalk. Signals which come from higher impedance sources (e.g., over 5 kΩ) will have a relatively higher level of crosstalk. For applications where signals have high source impedance, an operational amplifier buffer in front of the AD781 is required. The AD711 (precision BiFET op amp) is recommended for these applications.

HIGH FREQUENCY SAMPLING

Aperture jitter and distortion are the primary factors which limit frequency domain performance of a sample-and-hold amplifier. Aperture jitter modulates the phase of the hold command and produces an effective noise on the sampled analog input. The magnitude of the jitter induced noise is directly related to the frequency of the input signal.

A graph showing the magnitude of the jitter induced error vs. frequency of the input signal is given in Figure 6.

The accuracy in sampling high frequency signals is also constrained by the distortion and noise created by the sample-and-hold. The level of distortion increases with frequency and reduces the "effective number of bits" of the conversion.

Measurements of Figures 7 and 8 were made using a 14-bit A/D converter with V_{IN} = 10 V p–p and a sample frequency of 100 kSPS.

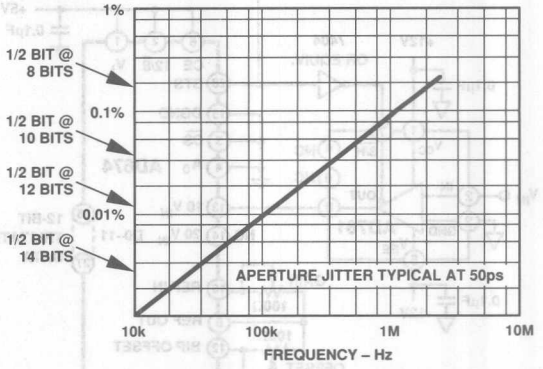

Figure 6. Error Magnitude vs. Frequency

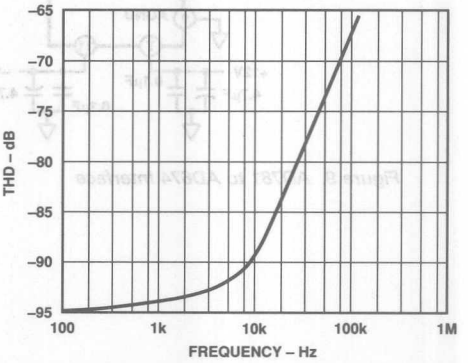

Figure 7. Total Harmonic Distortion vs. Frequency

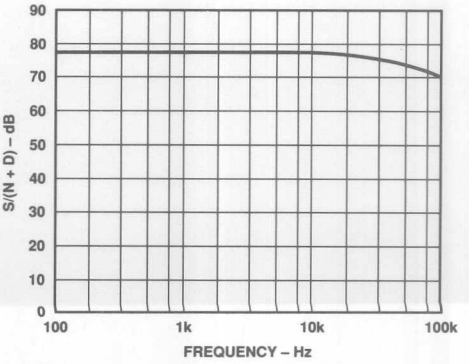

Figure 8. Signal/(Noise and Distortion) vs. Frequency

AD781, a high linearity, low aperture jitter SHA and the AD674 a 12-bit high speed ADC. The time between the AD674 status line going high and the actual start of conversion allows the AD781 to settle to 0.01%. As a result, the AD674 status line can be used to control the AD781; only an inverter is needed to interface the two devices.

PRELIMINARY TECHNICAL DATA

PRODUCT DESCRIPTION

The AD783 is a high speed, monolithic sample-and-hold amplifier (SHA). The AD783 guarantees a maximum acquisition time of 250 ns to 0.01% over temperature. The AD783 is specified and tested for hold mode total harmonic distortion with input frequencies up to 500 kHz. The AD783 is configured as a unity gain amplifier and uses a self-correcting architecture that minimizes hold mode errors and ensures accuracy over temperature. The AD783 is self-contained and requires no external components or adjustments.

The AD783 will acquire a full-scale input in less than 250 ns and will retain the held value with a droop rate of 0.02 μV/μs. Excellent linearity and hold mode dc and dynamic performance make the AD783 ideal for high speed 12- and 14-bit analog-to-digital converters.

The AD783 is manufactured on Analog Devices' ABCMOS process which merges high performance, low noise bipolar circuitry with low power CMOS to provide an accurate, high speed, low power SHA.

The AD783 is specified for three temperature ranges. The J grade device is specified for operation from 0°C to +70°C, the A grade from −40°C to +85°C and the S grade from −55°C to +125°C. The J and A grades are available in 8-pin plastic DIP packages. The S grade is available in an 8-pin cerdip package.

*Protected by U.S. Patent Number 4,962,325.

PRODUCT HIGHLIGHTS

1. Fast acquisition time (250 ns), low aperture jitter (50 ps) and fully specified hold mode distortion make the AD783 an ideal SHA for sampling systems.
2. Low droop (0.02 μV/μs) and internally compensated hold mode error result in superior system accuracy.
3. Low power (95 mW typical), complete functionality and small size make the AD783 an ideal choice for a variety of high performance applications.
4. The AD783 requires no external components or adjustments.
5. The AD783 is an excellent choice as a front-end SHA for high speed analog-to-digital converters such as the AD671, AD7586, AD674B, AD774B, AD7572 and AD7672.
6. Fully specified and tested hold mode distortion guarantees the performance of the SHA in sampled data systems.

DEFINITIONS OF SPECIFICATIONS

Acquisition Time—The length of time that the SHA must remain in the sample mode in order to acquire a full-scale input step to a given level of accuracy.

Small Signal Bandwidth—The frequency at which the held output amplitude is 3 dB below the input amplitude, under an input condition of a 100 mV p–p sine wave.

Full Power Bandwidth—The frequency at which the held output amplitude is 3 dB below the input amplitude, under an input condition of a 5 V p–p sine wave.

Effective Aperture Delay—The difference between the switch delay and the analog delay of the SHA channel. A negative number indicates that the analog portion of the overall delay is greater than the switch portion. This effective delay represents the point in time, relative to the hold command, that the input signal will be sampled.

Aperture Jitter—The variations in delay for successive samples. Aperture jitter puts an upper limit on the maximum frequency that can be accurately sampled.

Hold Settling Time—The time required for the output to settle to within a specified level of accuracy of its final held value after the hold command has been given.

Droop Rate—The drift in output voltage while in the hold mode.

Feedthrough—The attenuated version of a changing input signal that appears at the output when the SHA is in the hold mode.

Hold Mode Offset—The difference between the input signal and the held output. This offset term applies only in the hold mode and includes the error caused by charge injection and all other internal offsets. Hold mode offset is specified with an input of 0 V.

Sample Mode Offset—The difference between the input and output signals when the SHA is in the sample mode.

Nonlinearity—The deviation from a straight line on a plot of input vs. (held) output as referenced to a straight line drawn between endpoints, over an input range of −2.5 V and +2.5 V.

Gain Error—Deviation from a gain of +1 on the transfer function of input vs. held output.

Power Supply Rejection Ratio—A measure of change in the held output voltage for a specified change in the positive or negative supply.

Sampled DC Uncertainty—The internal rms SHA noise that is sampled onto the hold capacitor.

Hold Mode Noise—The rms noise at the output of the SHA while in the hold mode, specified over a given bandwidth.

Total Output Noise—The total rms noise that is seen at the output of the SHA while in the hold mode. It is the rms summation of the sampled dc uncertainty and the hold mode noise.

Output Drive Current—The maximum current the SHA can source (or sink) while maintaining a change in hold mode offset of less than 2.5 mV.

Total Harmonic Distortion (THD)—THD is the ratio of the rms sum of the first six harmonic components to the rms value of a full-scale input signal and is expressed as a percentage or in decibels.

Signal-to-Noise and Distortion Ratio (S/N+D)—S/N+D is the ratio of the rms value of the measured input signal to the rms sum of all other spectral components below the Nyquist frequency, including harmonics but excluding dc.

Intermodulation Distortion (IMD)—With inputs consisting of sine waves at two frequencies, fa and fb, any device with nonlinearities will create distortion products, of order (m + n), at sum and difference frequencies of mfa ± nfb, where m, n = 0, 1, 2, 3 . . . Intermodulation terms are those for which m or n is not equal to zero. For example, the second order terms are (fa + fb) and (fa − fb) and the third order terms are (2 fa + fb), (2 fa − fb), (fa + 2 fb) and (2 fb − fa). The IMD products are expressed as the decibel ratio of the RMS sum of the measured input signals to the RMS sum of the distortion terms. The two signals are of equal amplitude and the peak value of their sums is −0.5 dB from full scale. The IMD products are normalized to a 0 dB input signal.

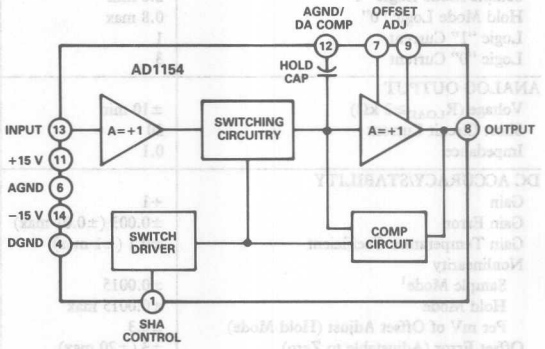
AD1154



FEATURES

- Low Nonlinearity: ±7.6 ppm max (1/2 LSB @ 16-Bit Accuracy)
- Fast Acquisition Time to ±0.00076%: 3.5 μs
- Low Droop Rate: 0.02 μV/μs
- Aperture Jitter: 150 ps
- ±10 V Input Range
- Hold Mode Feedthrough Rejection of −106 dB
- 14-Pin Metal DIP
- Gain of +1 V/V
- Low Cost

APPLICATIONS

- Medical and Analytical Instrumentation
- Automatic Test Equipment
- Data Acquisition for Signal Processing
- Simultaneous Sample-and-Hold
- Peak Measurement Detection
- Event Analysis

FUNCTIONAL BLOCK DIAGRAM

GENERAL DESCRIPTION

The AD1154 is a high accuracy, low cost sample-and-hold amplifier (SHA) designed to be used in high resolution data acquisition systems. It is complete with internal hold capacitor and proprietary capacitor trimmed compensation circuitry. Its accuracy (0.00076% of full scale range) and dynamic performance allow it to be used with high speed 16-bit A/D converters. The AD1154's low price enables users to upgrade the front end performance of 14-bit systems without increasing system cost. Its gain accuracy and droop rate in "hold" mode also allow accurate conversion by slower 16-bit A/D converters having conversion times of up to 7.6 ms.

The AD1154 is a hybrid noninverting sample-and-hold amplifier (SHA) with a gain of +1 V/V. It can be utilized in most inverting SHA applications by inverting the digital data. The AD1154 is packaged in a compact 14-pin metal DIP.

Typical applications for the AD1154 include data acquisition systems, strobed measurement systems, peak hold circuits and simultaneous sample-and-hold functions. The AD1154 is available in two grades, both operating over the −25°C to +85°C temperature range. The "A" grade is specified for 15-bit accurate systems, while the "B" grade offers superior performance for true 16-bit applications.

PRODUCT HIGHLIGHTS

1. Fast acquisition and low jitter make it the right choice for high speed, high accuracy data acquisition.
2. Its low droop rate (0.02 μV/μs) allows it to be used in slower systems without noticeable performance degradation.
3. The AD1154 is ideal for systems requiring wide dynamic range.
4. Low price reduces overall system cost.
5. Unity gain buffer architecture allows ease of use.

TERMINOLOGY

Accuracy is the peak deviation of the output from a straight line through the endpoints of the transfer function. It is expressed as a percentage of the full scale output range. Note that this parameter is measured in hold mode because the actual voltage to be converted is the voltage present at the output of the device during the hold mode.

Acquisition Time is the time required by the device to reach its final value within a given error band after the sample/track command has been given assuming that the input amplifier has settled. This includes switch delay time, slewing time and settling time for a given output voltage change.

Aperture Time is the time required after the hold command for the switch to open fully. The sample is, in effect, delayed by this interval, and the hold command would have to be advanced by this amount for precise timing.

Aperture Jitter is the range of variation in the aperture time. If the aperture time is "tuned out" by advancing the hold command a suitable amount, this spec establishes the ultimate timing error, hence, the maximum sampling frequency to a given resolution.

Charge Transfer (or offset step or pedestal) is the charge transferred to the storage capacitor when switching to the hold mode.

Droop Rate is the rate of change in output voltage over time while in the hold mode. The droop rate will determine how long a signal can be accurately held before it changes more than 1 LSB.

Feedthrough is the fraction of the input signal variation or ac input waveform that appears at the output in hold. It is caused by stray capacitive coupling from the input to the storage capacitor, principally across the open switch.

Small Signal Bandwidth is the maximum analog signal frequency that can be tracked before the gain is reduced by 3 dB. This assumes the signal amplitude is small enough so as not to be slew rate limited.

Switching Transient Settling Time is the time required for the device to stabilize in the hold mode to within specified limits of its final value after the hold mode signal has been given.

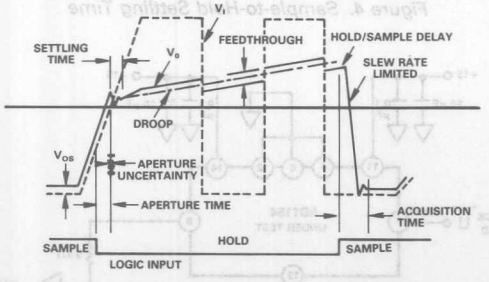

Figure 7. T/H Characteristics

INVERTING VS. NONINVERTING ARCHITECTURE

The AD1154 has a gain of +1 V/V. Many S/H amplifiers use an inverting architecture and hence have a gain of −1 V/V. The AD1154, because of its noninverting architecture, does not have an externally accessible summing point. This pin is found on most inverting S/Hs and is typically not used. In applications where the summing junction is not connected, the AD1154 can be used as a direct hardware replacement by tying Pin 12 to ground, but the output is of opposite polarity.

GROUNDING CONSIDERATIONS

The AD1154 is a true 16-bit performance sample/hold amplifier. In order to insure proper operation of the device, great care must be taken in managing the ground tracks. It is recommended that Pins 4, 6 and 12 of the AD1154 be tied together directly outside of the package. This point should then be tied to the analog ground of the A/D converter, as shown in Figure 8. This track should be as short and wide as possible to minimize voltage drops. Also note from the figure that any other analog grounds in the signal path should be joined to the A/D converter analog ground.

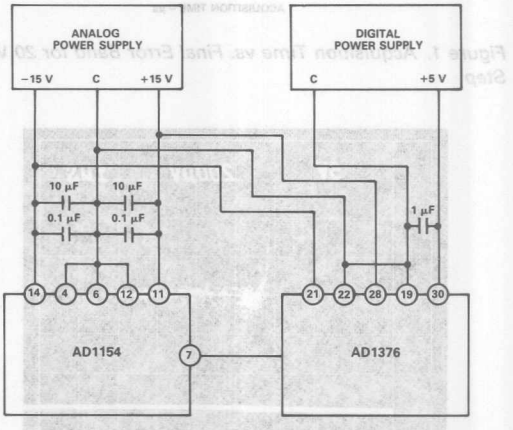

Figure 8. Basic Grounding and Power Supply Bypassing Practice

DIELECTRIC ABSORPTION COMPENSATION

The hold capacitor used in the AD1154 is a high quality ceramic chip capacitor. This capacitor's dielectric absorption characteristics are typically better than high quality film capacitors. In addition, the AD1154 provides a means for compensating for the dielectric absorption of the capacitor if better performance is required. If dielectric absorption compensation is not used, Pin 12 should be tied to ground. Please refer to the section titled "DISCUSSION OF DIELECTRIC ABSORPTION" for more detailed information.

POWER SUPPLY BYPASSING

The AD1154 utilizes high speed amplifiers in its design. These amplifiers require quiet power supplies that are free from spikes. For maximum performance it is recommended that both power supplies be bypassed with 0.1 µF ceramic capacitors in parallel with 10 µF tantalum capacitors located as close to the device as possible (see Figure 8).

DISCUSSION OF DIELECTRIC ABSORPTION

The hold capacitor of the AD1154 was chosen for its low dielectric absorption (D.A.) characteristics. D.A. is directly affected by the sample/hold mode switching durations and input levels. The AD1154 provides the user with a pin for external D.A. compensation circuitry. The AD1154's uncompensated D.A. performance is inherently superior, and in most applications the D.A. compensation pin should be connected to ground. Where additional compensation is desired to tailor the AD1154 to a specific user's application, only three resistors and a capacitor are required to optimize the AD1154's D.A. performance (see Figure 11).

If a capacitor is charged to a voltage, discharged for a moderate period of time, and then open circuited, the voltage on the capacitor will begin to creep back towards its initial value. This creep voltage is known as dielectric absorption. Dielectric absorption occurs because the dielectric material doesn't polarize instantly, the molecules need time to align themselves. As a result, not all of the energy stored in a capacitor can be quickly recovered upon discharge.

A first order model of the hold capacitor to include dielectric absorption effects is shown in Figure 9. In addition to the main capacitance, C_M, and the insulation resistance, R_I, there is an

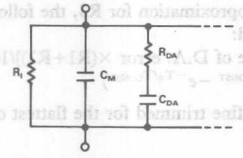

Figure 9. First Order Model of D. A. Effects

R_{DA} and a C_{DA}. When the capacitor is charged to some value, C_{DA} is also charged. When the capacitor is discharged, C_{DA} also discharges. But it must discharge through R_{DA}, and, if the capacitor is not discharged for a long enough period of time, C_{DA} will not completely discharge. As a result, when the capacitor is open circuited, C_{DA} will discharge into C_M causing the voltage across it to creep back towards its initial value. The actual model of the capacitor should contain additional R_{DA}s and C_{DA}s with increasing time constants in parallel with the one shown.

Figure 10 shows a circuit suitable for measuring the dielectric absorption of sample/hold amplifiers. The circuit operates as follows: R1 and C1 set the frequency of the SHA control; R2 and C2 set the amount of acquisition time allowed for the SHA. See the timing diagram of Figure 10.

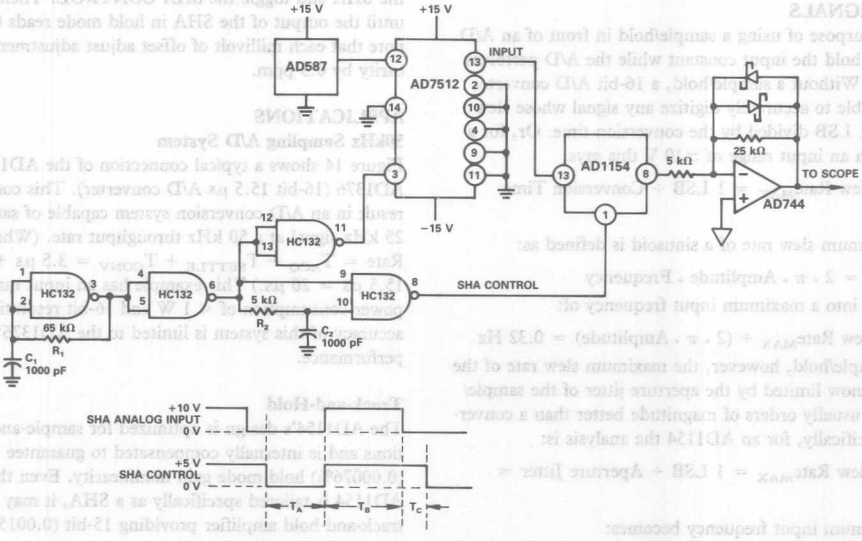

Figure 10. Dielectric Absorption Measurement Circuit

During T_B, the CONTROL line is high, the AD1154 is in the sample mode and the analog input charges the hold capacitor to +10 V. During T_C the analog input to the SHA is switched to ground, effectively shorting the hold capacitor for the remainder of the sample period. During T_A, the SHA is switched into hold mode and the hold capacitor is open circuited. The dielectric rebound can be observed on the oscilloscope during T_A. Refer to Figure 12.

Note that the dielectric absorption error is dependent on several factors: it is a function of how long the capacitor is charged (T_B), how long it is discharged (T_C) and how long it is observed while open circuited (T_A). These parameters can be modified by changing R1, R2, C1 and C2.

The AD1154 provides a pin to compensate for dielectric absorption. To use it, the circuit of Figure 11 must be employed.

To find the optimum values for R1, R2, R3 and C1 follow this procedure:

1. Adjust the D.A. measurement circuit (see Figure 10) to represent a typical sampling rate.
2. Observe the dielectric absorption error on the oscilloscope.
3. Pick (R1||R2) • C1 to be equal to the approximate time constant (T_{const}) of the dielectric rebound on the oscilloscope (see photo in Figure 12).

4. R3 is used to adjust the magnitude of the compensation. To find an initial approximation for R3, the following relationship can be used:
   $R3 = [\text{Magnitude of D.A. error} \times (R1+R2)]/10 \times 1/(e^{-T_C/T_{CONST}} - e^{-T_A/T_{CONST}})$
5. R3 can then be fine trimmed for the flattest output during hold.

Using this method it is possible to reduce the effect of dielectric absorption by a factor of four or five. The typical values for resistors and capacitor given in Figure 11 are for a sample time of 20 μs, acquisition time of 5 μs and a hold time of 20 μs. When determining the values, R3 should be less than 10 Ω, and C1 should be as small as possible.

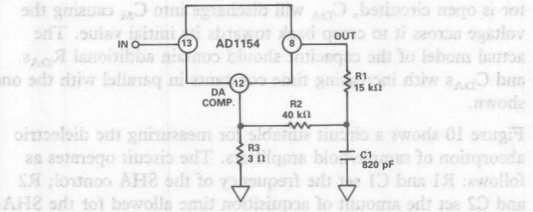

Figure 11. D/A Compensation Circuit with Typical Values

DYNAMIC SIGNALS

The primary purpose of using a sample/hold in front of an A/D converter is to hold the input constant while the A/D performs its conversion. Without a sample/hold, a 16-bit A/D converter would not be able to accurately digitize any signal whose slew rate exceeded 1 LSB divided by the conversion time. Or, for a 15 μs A/D with an input range of ±10 V this says:

$\text{Input Signal Slew Rate}_{MAX}$ = 1 LSB ÷ Conversion Time
= 20.3 V/S

Since the maximum slew rate of a sinusoid is defined as:

$\text{Slew Rate}_{MAX} = 2 \cdot \pi \cdot \text{Amplitude} \cdot \text{Frequency}$

This translates into a maximum input frequency of:

$F_{IN\ MAX}$ = $\text{Slew Rate}_{MAX} \div (2 \cdot \pi \cdot \text{Amplitude})$ = 0.32 Hz

By using a sample/hold, however, the maximum slew rate of the input signal is now limited by the aperture jitter of the sample/hold, which is usually orders of magnitude better than a conversion time. Specifically, for an AD1154 the analysis is:

$\text{Input Signal Slew Rate}_{MAX}$ = 1 LSB ÷ Aperture Jitter = 2.035 V/μs.

Now the maximum input frequency becomes:

$F_{IN\ MAX}$ = $\text{Slew Rate}_{MAX} \div (2 \cdot \pi \cdot \text{Amplitude})$ = 32.4 kHz.

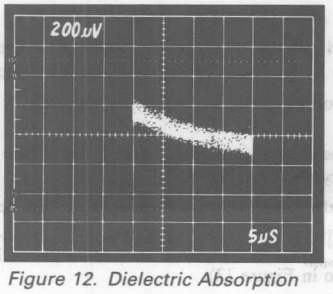

Figure 12. Dielectric Absorption

This represents a dramatic improvement over using the A/D converter by itself. The AD1154's 222 kHz throughput ($1/(T_{ACQ} + T_{SETT})$) and 150 ps aperture jitter allow it to digitize input signals of up to 32 kHz to 16-bit accuracy or up to a 128 kHz signal to 14-bits.

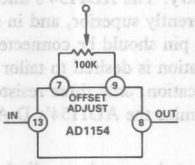

Figure 13. Offset Adjust Circuit

OPERATING INSTRUCTIONS

Offset Adjust

In most data acquisition systems only one offset adjustment is made. Usually the offset adjust of the A/D converter is used to null the combined system offsets. However, the offset or pedestal of the AD1154 can be nulled by connecting a trim potentiometer between Pins 7 and 9, and tying the wiper to +15 V (refer to Figure 13.) To null the pedestal, ground the input of the SHA and toggle the SHA CONTROL. Then adjust the pot until the output of the SHA in hold mode reads 0 V. Please note that each millivolt of offset adjust adjustment degrades linearity by 0.3 ppm.

APPLICATIONS

50kHz Sampling A/D System

Figure 14 shows a typical connection of the AD1154 to the AD1376 (16-bit 15.5 μs A/D converter). This combination will result in an A/D conversion system capable of sampling a 25 kHz signal at a 50 kHz throughput rate. (Where Throughput Rate = $T_{ACQ} + T_{SETTLE} + T_{CONV}$ = 3.5 μs + 1 μs + 15.5 μs = 20 μs.) This example has an input range of ±10 V, power consumption of < 1 W and 16-bit resolution. The accuracy of this system is limited to the AD1376's 14-bit performance.

Track-and-Hold

The AD1154's design is optimized for sample-and-hold applications and is internally compensated to guarantee 16-bit (0.00076%) hold mode gain nonlinearity. Even though the AD1154 is tailored specifically as a SHA, it may be used as a track-and-hold amplifier providing 15-bit (0.0015%) track mode gain nonlinearity.

GENERAL DESCRIPTION

The AD9100 is a monolithic track-and-hold amplifier which sets a new standard for high speed and high dynamic range applications. It is fabricated in a mature high speed complementary bipolar process. In addition to innovative design topologies, a custom package is utilized to minimize parasitics and optimize dynamic performance.

Acquisition time (hold to track) is 13 ns to 0.1% accuracy, and 16 ns to 0.01%. The AD9100 boasts superlative hold-mode frequency domain performance; when sampling at 30 MSPS hold mode distortion is less than −83 dBfs for analog frequencies up to 12 MHz; and −74 dBfs at 20 MHz. The AD9100 can also drive capacitive loads up to 100 pF with little degradation in acquisition time; it is therefore well suited to drive 8- and 10-bit flash converters at clock speeds to 50 MSPS. With a spectral noise density of 3.3 nV/$\sqrt{Hz}$ and feedthrough rejection of 83 dB at 20 MHz, the AD9100 is well suited to enhance the dynamic range of many 8- to 16-bit systems.

*Patent pending.

The AD9100 is "user friendly" and easy to apply: (1) it requires +5 V/−5.2 V power supplies; (2) the hold capacitor and switch power supply decoupling capacitors are built into the DIP package; (3) the encode clock is differential ECL to minimize clock jitter; (4) the input resistance is typically 800 kΩ; (5) the analog input is internally clamped to prevent damage from voltage transients.

The AD9100 is available in a 20-lead side-brazed "skinny DIP" package. Commercial, industrial, and military temperature grade parts are available. Consult the factory for information about the availability of surface mount packages and 883-qualified devices.

PRODUCT HIGHLIGHTS

1. Hold Mode Distortion is guaranteed.
2. Monolithic construction.
3. Analog input is internally clamped to protect against overvoltage transients and ensure fast recovery.
4. Output is short circuit protected.
5. Drives capacitive loads to 100 pF.
6. Differential ECL clock inputs.

NOTES
[1]Absolute maximum ratings are limiting values to be applied individually, and beyond which the serviceability of the circuit may be impaired. Functional operability is not necessarily implied. Exposure to absolute maximum rating conditions for an extended period of time may affect device reliability.
[2]Analog input voltage should not exceed $\pm V_S$.
[3]The "Full" temperature specifications refer to the ambient temperature for the DIP package only after a power soak. AD9100JD: 0°C to +70°C. AD9100AD: −40°C to +85°C. AD9100SD: −55°C to +125°C. θ_{JA} = 38°C/W; this is valid with the device mounted flush to a grounded 2-oz copper clad board with 16 sq. inches of surface area and no air flow.
[4]The input to the AD9100 is internally clamped at ±2.3 V. The internal input series resistance is nominally 50 Ω.
[5]Hold mode noise is proportional to the length of time a signal is held. For example, if the hold time (t_H) is 20 ns, the accumulated noise is typically 6 μV (300 V/s × 20 ns). This value must be combined with the track mode noise to obtain total noise.
[6]Min and max droop rates are based on the military temperature range (−55°C to +125°C). Refer to the "Droop Rate vs Temperature" chart for min/max limits over the commercial and industrial ranges.
Specifications subject to change without notice.

EXPLANATION OF TEST LEVELS

Test Level

I – 100% production tested.
II – 100% production tested at +25°C, and sample tested at specified temperatures.
III – Periodically sample tested.
IV – Parameter is guaranteed by design and characterization testing.
V – Parameter is a typical value only.
VI – All devices are 100% production tested at +25°C. 100% production tested at temperature extremes for extended temperature devices; sample tested at temperature extremes for commercial/industrial devices.

ORDERING GUIDE

Model[1]	Temperature Range	Package Option[2]
AD9100JD	0°C to +70°C	D-20
AD9100AD	−40°C to +85°C	D-20
AD9100SD	−55°C to +125°C	D-20

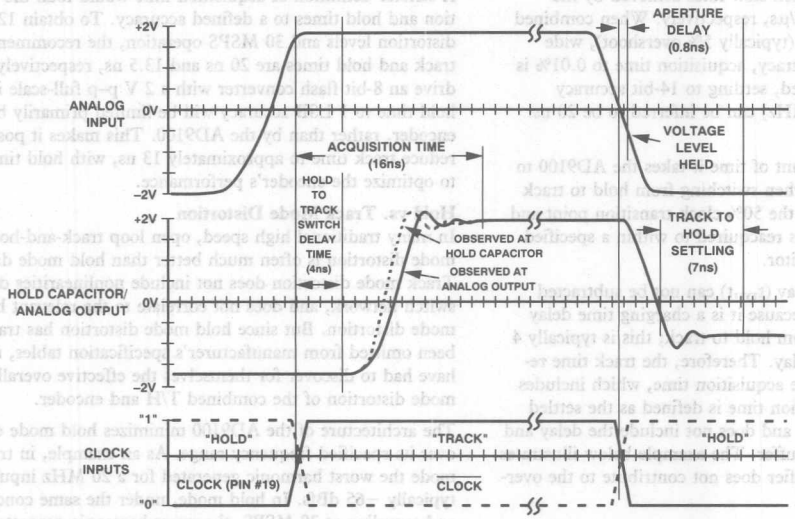
DIP PINOUTS

LCC PINOUTS



Acquisition Time is the amount of time it takes the AD9100 to reacquire the analog input when switching from hold to track mode. The interval starts at the 50% clock transition point and ends when the input signal is reacquired to within a specified error band at the hold capacitor.

Analog Delay is the time required for an analog input signal to propagate from the device input to output.

Aperture Delay tells when the input signal is actually sampled. It is the time difference between the analog propagation delay of the front-end buffer and the control switch delay time. (The time from the hold command transition to when the switch is opened.) For the AD9100, this is a positive value which means that the switch delay is longer than the analog delay.

Aperture Jitter is the random variation in the aperture delay. This is measured in ps-rms and results in phase noise on the held signal.

Droop Rate is the change in output voltage as a function of time (dV/dt). It is measured at the AD9100 output with the device in hold mode and the input held at a specified dc value; the measurement starts immediately after the T/H switches from track to hold.

AD9100 Timing Diagram

Feedthrough Rejection is the ratio of the input signal to the output signal when in hold mode. This is a measure of how well the switch isolates the input signal from feeding through to the output.

Hold to Track Switch Delay is the time delay from the track command to the point when the output starts to change and acquire a new signal.

Pedestal Offset is the offset voltage step measured immediately after the AD9100 is switched from track to hold with the input held at zero volts. It manifests itself as an added offset during the hold time.

Track to Hold Settling Time is the time necessary for the track to hold switching transient to settle to within 1 mV of its final value.

Track to Hold Switching Transient is the maximum peak switch induced transient voltage which appears at the AD9100 output when it is switched from track to hold.

THEORY OF OPERATION

The AD9100 utilizes a new track and hold architecture. Previous commercially available high speed track and holds used a front end open loop input buffer, followed by a diode bridge, hold capacitor, and output buffer (closed or open loop) with a FET device connected to the hold capacitor. This architecture required mixed device technology and, usually, hybrid construction. The sampling rate of these hybrids has been limited to 20 MSPS for 12-bit accuracy. Distortion generated in the front-end amplifier/bridge limited the dynamic range performance to the "mid-70 dBfs" for analog input signals of less than 10 MHz. Broadband and switch-generated noise limited the SNR of previous track and holds to about 70 dB.

The AD9100 is a monolithic device using a high frequency complementary bipolar process to achieve new levels of high speed precision. Its patent pending architecture breaks from the traditional architecture described above. (See the block diagram on the first page.) The switching type bridge has been integrated into the first stage closed loop input amplifier. This innovation provides error (distortion) correction for both the switch and amplifier, while still achieving slew rates representative of an open-loop design. In addition, acquisition slew current for the hold capacitor is higher than standard diode bridge and switch configurations, removing a main contributor to the limits of maximum sampling rate and input frequency.

Switching circuits in the device use current steering (versus voltage switching) to provide improved isolation between the switch and analog sections. This results in low aperture time sensitivity to the analog input signal, and reduced power supply and analog switching noise. Track to hold peak switching transient is typically only 6 mV and settles to less than 1 mV in 7 ns. In addition, pedestal sensitivity to analog input voltage is very low (0.6 mV/V) and being first order linear does not significantly affect distortion.

The closed-loop output buffer includes zero voltage bias current cancellation, which results in high-temperature droop rates equivalent to those found in FET type inputs. The buffer also provides first order quasistatic bias correction resulting in an extremely high input resistance and very low droop sensitivity vs. input voltage level (typically less than 1.5 mV/V−μs.) This closed-loop architecture inherently provides high speed loop correction and results in low distortion under heavy loads.

The extremely fast time constant linearity (7 ns to 0.01% for a 2 V step) ensures that the output buffer does not limit the AD9100 sampling rate or analog input frequency. (The acquisition and settling time are primarily limited only by the input amplifier and switch.) The output is transparent to the overall AD9100 hold mode distortion levels for loads as low as 250 Ω.

Full-scale track and acquisition slew rates achieved by the AD9100 are 800 and 1000 V/μs, respectively. When combined with excellent phase margin (typically 5% overshoot), wide bandwidth, and dc gain accuracy, acquisition time to 0.01% is only 16 ns. Though not tested, settling to 14-bit accuracy (−88 dB distortion @ 2.3 MHz) can be inferred to be 20 ns.

Acquisition Time

Acquisition time is the amount of time it takes the AD9100 to reacquire the analog input when switching from hold to track mode. The interval starts at the 50% clock transition point and ends when the input signal is reacquired to within a specified error band at the hold capacitor.

The hold to track switch delay ($t_{DH}t$) can not be subtracted from this acquisition time because it is a charging time delay that occurs when moving from hold to track; this is typically 4 to 6 ns and is the longest delay. Therefore, the track time required for the AD9100 is the acquisition time, which includes t_{DHT}. Note that the acquisition time is defined as the settled voltage at the hold capacitor and does not include the delay and settling time of the output buffer. The example below illustrates why the output buffer amplifier does not contribute to the overall AD9100 acquisition time.

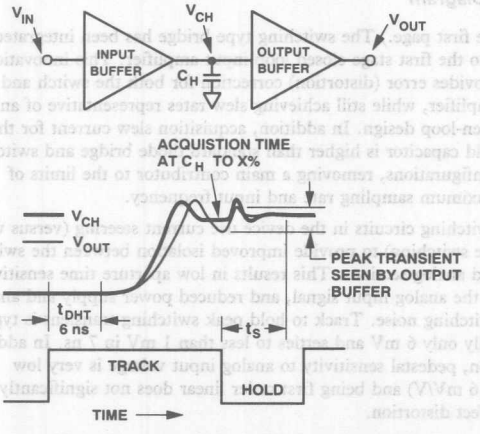


Figure 1. Acquisition Time Diagram

The exaggerated illustration in Figure 1 shows that V_{CH} has settled to within x% of its final value, but V_{OUT} (due to slew rate limitations, finite BW, power supply ringing, etc.) has not settled during the track time. However, since the output buffer always "tracks" the front end circuitry, it "catches up" during the hold time and directly superimposes itself (less about 600 ps of analog delay) to V_{CH}. Since the small-signal settling time of the output buffer is about 1.8 ns to ±1 mV and is significantly less than the specified hold time, acquisition time should be referenced to the hold capacitor.

Note that most of the hold settling time and output acquisition time are due to the input buffer and the switch network. For output acquisition time, the output buffer contributes only about 5 ns of the total; in hold mode, it contributes only 1.8 ns (as stated above).

A stricter definition of acquisition time would total the acquisition and hold times to a defined accuracy. To obtain 12 bit + distortion levels and 30 MSPS operation, the recommended track and hold times are 20 ns and 13.5 ns, respectively. To drive an 8-bit flash converter with a 2 V p–p full-scale input, hold time to 1 LSB accuracy will be limited primarily by the encoder, rather than by the AD9100. This makes it possible to reduce track time to approximately 13 ns, with hold time chosen to optimize the encoder's performance.

Hold vs. Track Mode Distortion

In many traditional high speed, open loop track-and-holds, track mode distortion is often much better than hold mode distortion. Track mode distortion does not include nonlinearities due to the switch network, and does not correlate to the relevant hold mode distortion. But since hold mode distortion has traditionally been omitted from manufacturer's specification tables, users have had to discover for themselves the effective overall hold mode distortion of the combined T/H and encoder.

The architecture of the AD9100 minimizes hold mode distortion over its specified frequency range. As an example, in track mode the worst harmonic generated for a 20 MHz input tone is typically −65 dBfs. In hold mode, under the same conditions and sampling at 30 MSPS, the worst harmonic generated is −74 dBfs. The reason is the output buffer in hold mode has only dc distortion relevancy. With its inherent linearity (7 ns settling to 0.01%), the output buffer has essentially settled to its dc distortion level even for track plus hold times as short as 30 ns. For a traditional open-loop output buffer, the ac (track mode) and dc (hold mode) distortion levels are often the same.

Droop Rate

Droop rate does not necessarily affect a track and hold's distortion characteristics. If the droop rate is constant versus the input voltage for a given hold time, it manifests itself as a dc offset to the encoder. For the AD9100, the droop rate is typically ±1 mV/μs. If a signal is held for 1 μs, a subsequent encoder would see a 1 mV offset voltage. If there is no droop sensitivity to the held voltage value, the 1 mV offset would be constant and "ride" on the input signal and introduce no hold-mode nonlinearities.

In instances in which droop rate varies proportionately to the magnitude of the held voltage signal level, a gain error only is introduced to the A/D encoder. The AD9100 has a droop sensitivity to the input level of 1.5 mV/V−μsec. For a 2 V p–p input signal, this translates to a 0.15%/μs gain error and does not cause additional distortion errors.

For the AD9100, droop sensitivity to input level is insignificant. However, *hold times longer than about 2 μs can cause distortion* due to the R × C_H time constant at the hold capacitor. In addition, hold mode noise will increase linearly vs. hold time and thus degrade SNR performance.

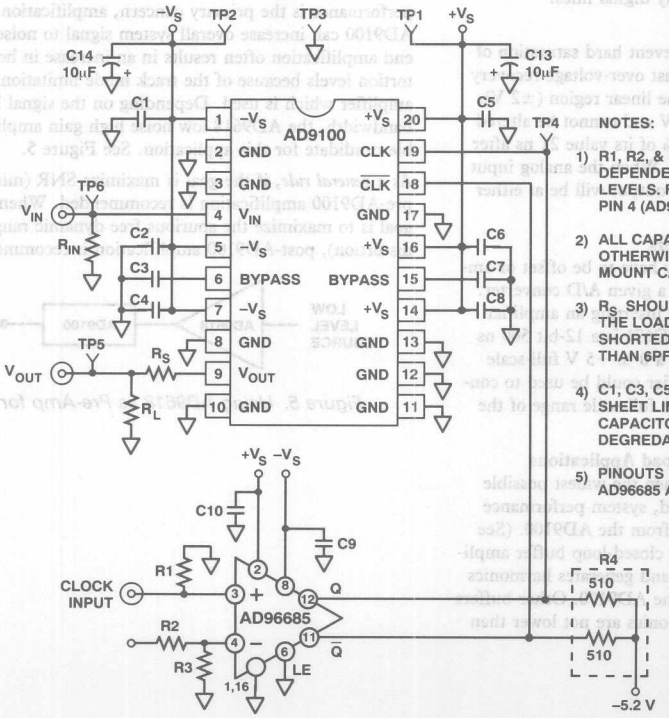
Layout Considerations

For best performance results, good high speed design techniques must be applied. The component (top) side ground plane should be as large as possible; two-ounce copper cladding is preferable. All runs should be as short as possible, and decoupling capacitors must be used.

Figure 2 is the schematic of a recommended AD9100 evaluation board. (Contact factory concerning availability of assembled boards.) All 0.01 μF decoupling capacitors should be low induc-

tance surface mount devices (P/N 05085C103MT050 from AVX) and connected on the component side within 30 mils of the designated pins; with the other sides soldered directly to the top ground plane.

The 10 μF low frequency power supply tantalum decoupling capacitors should be located within 1.5 inches of the AD9100. The common 0.01 μF supply capacitors can be wired together. The common power supply bus (connected to the 10 μF capacitor and power supply source) can be routed to the underside of the board to the daisy chain wired 0.01 μF supply capacitors.

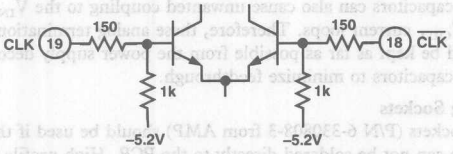


For remote input and/or output drive applications, controlled impedances are required to minimize line reflections which will reduce signal fidelity. When capacitive and/or high impedance levels are present, the load and/or source should be physically located within approximately one inch of the AD9100. Note that a series resistance, R_S, is required if the load is greater than 6 pF. (The Recommended R_S vs. CL chart in the "Typical Performance Section" shows values of R_S for various capacitive loads which result in no more than a 20% increase in settling time for loads up to 80 pF.) As much of the ground plane as possible should be removed from around the V_{IN} and V_{OUT} pins to minimize coupling onto the analog signal path.

While a single ground plane is recommended, the analog signal and differential ECL clock ground currents follow a narrow path directly under their common voltage signal line. To reduce reflections, especially when terminations are used for transmission line efficiency, the clock, V_{IN}, and V_{OUT} signals and respective ground paths should not cross each other; if they do, unwanted coupling can result.

High current ground transients via the high frequency decoupling capacitors can also cause unwanted coupling to the V_{IN} and V_{OUT} current loops. Therefore, these analog terminations should be kept as far as possible from the power supply decoupling capacitors to minimize feedthrough.

Using Sockets



Pin sockets (P/N 6-330808-3 from AMP) should be used if the device can not be soldered directly to the PCB. High profile or wire wrap type sockets will dramatically reduce the dynamic performance of the device in addition to increasing the case-to-ambient thermal resistance.

Driving the Encode Clock

The AD9100 requires a differential ECL clock command. Due to the high gain bandwidth of the AD9100 internal switch, the input clock should have a slew rate of at least 100 V/μs.

To obtain maximum signal to noise performance, especially at high analog input frequencies, a low jitter clock source is required. The AD9100 clock can be driven by an AD96685, an ultrahigh speed ECL comparator with very low jitter.

Clock/$\overline{\text{Clock}}$ Input Stage

Driving the Analog Input

Special care must be taken to ensure that the analog input signal is not compromised before it reaches the AD9100. To obtain maximum signal to noise performance, a very low phase noise analog source is required. In addition, input filtering and/or a low harmonic signal source is necessary to maximize the spurious free dynamic range. Any required filtering should be done close to the AD9100 and away from any digital lines.

Overdriving the Analog Input

The AD9100 has input clamps that prevent hard saturation of the output buffer, thereby providing fast over-voltage recovery when the analog input transitions to the linear region (±2 V). The clamps are set internally at ±2.3 V and cannot be altered by the user. The output settles to 0.1% of its value 21 ns after the over-voltage condition is alleviated. When the analog input is outside the linear region, the analog output will be at either +2.2 V or −2.2 V.

Matching the AD9100 to A/D Encoders

The AD9100's analog output level may have to be offset or amplified to match the full-scale range of a given A/D converter. This can generally be accomplished by inserting an amplifier after the AD9100. For example, the AD671 is a 12-bit 500 ns monolithic ADC encoder that requires a 0 to +5 V full-scale analog input. An AD84X series amplifier could be used to condition the AD9100 output to match the full-scale range of the AD671.

Ultralow Distortion/Low Resistive Load Applications

When driving low resistive loads or when the widest possible spurious free dynamic range is required, system performance can be improved by isolating the load from the AD9100. (See Figure 3.) The AD9620 low distortion closed-loop buffer amplifier has an input resistance of 800 kΩ and generates harmonics that are less than those generated by the AD9100. Other buffers should not be considered if their harmonics are not lower than those of the AD9100.

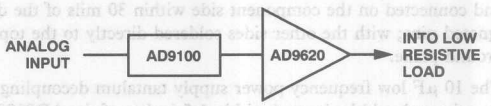


Figure 3. Using AD9620 as Isolation Amplifier

Super Nyquist Signals/Low Distortion

The AD9100 can be used to sample super-Nyquist signals, making high fidelity direct IF sampling practical. For applications in which the analog input signal is >20 MHz, some improvement in system level performance may be achieved if the analog input to the AD9100 is reduced, then gained up at the output by a low distortion amplifier such as the AD9617. See Figure 4.

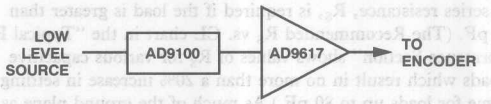

Figure 4. Using AD9617 as Post-Amp for AD9100

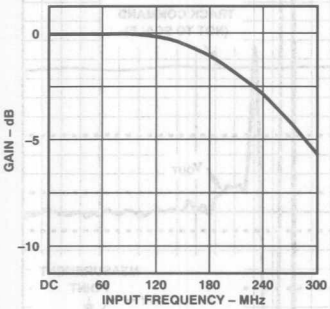
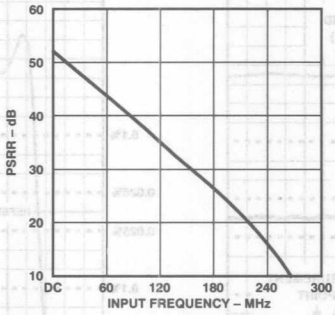


Low Noise Applications

When processing low level single event signals in which noise performance is the primary concern, amplification ahead of the AD9100 can increase overall system signal to noise ratio. Front-end amplification often results in an increase in hold mode distortion levels because of the track mode limitations of the amplifier which is used. Depending on the signal levels and bandwidth, the AD9618 low noise high gain amplifier is a possible candidate for this application. See Figure 5.



As a general rule, if the goal is maximize SNR (minimize noise), pre-AD9100 amplification is recommended. When the system goal is to maximize the spurious free dynamic range (minimize distortion), post-AD9100 amplification is recommended.

AD9100 Burn-in Circuit

CMOS Quad Sample-and-Hold Amplifier

SMP-04

FEATURES

- **Four Independent Sample-and-Holds**
- **Internal Hold Capacitors**
- **High Accuracy – 12-Bit**
- **Very Low Droop Rate (2mV/s Typ)**
- **Output Buffers Stable for $C_L \leq 500pF$**
- **TTL/CMOS Compatible Logic Inputs**
- **Single or Dual Supply Applications**
- **Monolithic Low Power CMOS Design**

APPLICATIONS

- **Signal Processing Systems**
- **Multichannel Data Acquisition Systems**
- **Automatic Test Equipment**
- **Medical and Analytical Instrumentation**
- **Event Analysis**
- **DAC Deglitching**

GENERAL DESCRIPTION

The SMP-04 is a monolithic quad sample-and-hold; it has four internal precision buffer amplifiers and internal hold capacitors. It is manufactured in PMI's advanced oxide isolated CMOS technology to obtain high accuracy, low droop rate and fast acquisition time required by data acquisition and signal processing systems. The device can acquire an 8-bit input signal to ±1/2 LSB in less than seven microseconds. The SMP-04 can operate from single or dual power supplies with TTL/CMOS logic compatibility. Its output swing includes the negative supply.

The SMP-04 is ideally suited for a wide variety of sample-and-hold applications including amplifier offset or VCA gain adjustments. One or more can be used with a single or multiple DACs to provide multiple set points within a system.

The SMP-04 offers significant cost and size reduction over equivalent module or discrete designs. It is available in a 16-pin hermetic or plastic DIP and surface mount SOIC packages. It is specified over the extended industrial temperature range of –40°C to +85°C. See SMP-04/883 data sheet for –55°C to +125°C specifications.

PACKAGE TYPE	Θ_{JA} (Note 1)	Θ_{JC}	UNITS
16-Pin CerDIP (Q)	94	12	°C/W
16-Pin Plastic DIP (P)	76	33	°C/W
16-Pin SO (S)	92	27	°C/W

NOTE:
1. Θ_{JA} is specified for worst case mounting conditions, i.e., Θ_{JA} is specified for device in socket for CerDIP and P-DIP packages; Θ_{JA} is specified for device soldered to printed circuit board for SO package.

CAUTION:
1. Stresses above those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. This is a stress rating only and function operation at or above this specification is not implied. Exposure to the above maximum rating conditions for extended periods may affect device reliability.
2. Digital inputs and outputs are protected; however, permanent damage may occur on unprotected units from high-energy electrostatic fields. Keep units in conductive foam or packaging at all times until ready to use. Use proper anti-static handling procedures.
3. Remove power before inserting or removing units from their sockets.

MAXIMUM OUTPUT VOLTAGE vs FREQUENCY

GENERAL INFORMATION

The SMP-04 is a quad sample-and-hold with each track-and-hold having its own input, output, control, and on-chip hold capacitor. The combination of four high-performance track-and-hold capacitors on a single chip greatly reduces board space and design time while increasing reliability.

After the device selection, the primary considerations in using track-and-holds are the hold capacitor and layout. The SMP-04 eliminates most of these problems by having the hold capacitors internal, eliminating the problems of leakage, feed-through, guard-ring layout and dielectric absorption.

POWER SUPPLIES

The SMP-04 is capable of operating with either single or dual supplies over a voltage range of 7 to 15 volts. Based on the supply voltages chosen, V_{DD} and V_{SS} establish the output voltage range, which is:

$$V_{SS} + .05V \leq V_{OUT} \leq V_{DD} - 2V$$

Note that several specifications, including acquisition time, offset and output voltage compliance will degrade for a total supply voltage of less than 7V. Positive supply current is typically 4mA with the outputs unloaded. The SMP-04 has an internally regulated TTL supply so that TTL/CMOS compatibility will be maintained over the full supply range.

Single Supply Operation Grounding Considerations – In single supply applications, it is extremely important that the V_{SS} (negative supply) pin be connected to a clean ground. This is because the hold capacitor is internally tied to V_{SS}. Any noise or disturbance in the ground will directly couple to the output of the sample-and-hold, degrading the signal-to-noise performance. It is advisable that the analog and digital ground traces on the circuit board be physically separated to reduce digital switching noise from entering the analog circuitry.

Power Supply Bypassing – For optimum performance, the V_{DD} supply pin must also be bypassed with a good quality, high-frequency ceramic capacitor. The recommended value is 0.1µF. In the case where dual supplies are used, V_{SS} (negative supply) bypassing is particularly important. Again this is because the internal hold capacitor is tied to V_{SS}. Good bypassing prevents high frequency noise from entering the sample-and-hold amplifier. A 0.1µF ceramic bypass capacitor is generally sufficient. For high noise environments, adding a 10µF tantalum capacitor in parallel with the 0.1µF provides additional protection.

Power Supply Sequencing – It may be advisable to have the V_{DD} turn on prior to having logic levels on the inputs. The SMP-04 has been designed to be resistant to latch-up, but standard precautions should still be taken.

OUTPUT BUFFERS (Pins 1, 2, 14, and 15)
The buffer offset specification is ±10mV; this is less than 1/2 LSB of an 8-bit DAC with 10V full scale. Change in offset over the output range is typically 3mV. The hold step is the magnitude of the voltage step caused when switching from sample-to-hold mode. This error is sometimes referred to as the pedestal error or sample-to-hold offset, and is about 1mV with little variation. The droop rate of a held channel is 2µV/ms typical and ±25µV/ms maximum.

The buffers are designed primarily to drive loads connected to ground. The outputs can source more than 1.2mA each, over the full voltage range and maintain specified accuracy. In split supply operation, symmetrical output swings can be obtained by restricting the output range to 2V from either supply.

On-chip SMP-04 buffers eliminate potential stability problems associated with external buffers; outputs are stable with capacitive loads up to 500pF. However, since the SMP-04's buffer outputs are not short-circuit protected, care should be taken to avoid shorting any output to the supplies or ground.

SIGNAL INPUT (Pins 3, 5, 11, and 12)
The signal inputs should be driven from a low impedance voltage source such as the output of an op amp. The op amp should have a high slew rate and fast settling time if the SMP-04's fast acquisition time characteristics are to be maintained. As with all CMOS devices, all input voltages should be kept within range of the supply rails ($V_{SS} \leq V_{IN} \leq V_{DD}$) to avoid the possibility of setting up a latch-up condition.

The internal hold capacitance is typically 60pF and the internal switch ON resistance is 4kΩ.

If single supply operation is desired, op amps such as the OP-21, OP-80, or OP-90 that have input and output voltage compliances including ground, can be used to drive the inputs. Split supplies, such as ±7.5V, can be used with the SMP-04 and the above mentioned op amps.

APPLICATION TIPS
All unused digital inputs should be connected to logic LOW and the analog inputs connected to analog ground. For connector-driven analog inputs that may become temporarily disconnected, a resistor to V_{SS} or analog ground should be used with a value ranging from 0.2 to 1MΩ.

Do not apply signals to the SMP-04 with power off unless the input current's value is limited to less than 10mA.

Track-and-holds are sensitive to layout and physical connections. For the best performance, the SMP-04 should not be socketed.

FREQUENCY DOMAIN PERFORMANCE
The SMP-04 has been characterized in the frequency domain for those applications that require capture of dynamic signals. See Figure 1a for typical 86.1kHz sample rate and an 8kHz input signal. Typically, the SMP-04 can sample at rates up to 85kHz. In addition to the maximum sample rate, a minimum sample pulse width will also be acceptable for a given design. Our testing shows a drop in performance as the sample pulse width becomes less than 4µs.

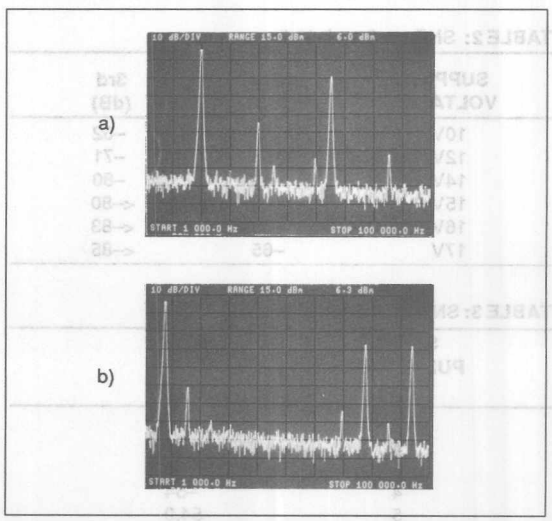

FIGURE 1: *Spectral response at a sampling frequency of 86kHz. Photo (a) shows a 20kHz carrier frequency, and photo (b) shows an 8kHz frequency.*

Optimizing Dynamic Performance of the SMP-04 – Various operating parameters such as input voltage amplitude, sampling pulse width and, as mentioned before, supply bypassing and grounding all have an effect on the signal-to-noise ratio. Table 1 shows the SNR versus input level for the SMP-04.
Distortion of the SMP-04 is reduced by increasing the supply voltage. This has the effect of increasing the positive slew rate. Table 2 shows data taken at 12.3kHz sample rate and 2kHz input frequency. Total harmonic distortion is dominated by the second and third harmonics.

Table 3 shows the effect of sampling pulse width on the SNR of the SMP-04. The recommended operating pulse width should be a minimum of 5 µs to achieve a good balance between acquisition time and SNR for the 1.4V_{p-p} signal shown. For larger swings the pulse width will need to be larger to account for the time required for the signal to slew the additional voltage. This could be used as a method of measuring acquisition time indirectly.

TABLE 1: SNR vs. V_{IN}

5	–54.9
6	–55
7	–55.3

Conditions: V_S = ±6V, V_{IN} = 1.4V_{p-p}, f_S =14.4kHz, f_{IN} = 1.8kHz

Sample-Mode Distortion Characteristics – Although designed as a sample-and-hold, the SMP-04 may be used as a straight buffer amplifier by configuring it in a continuous sample mode. This is done by connecting the $\overline{S/H}$ control pin to a logic LOW. Its buffer bandwidth is primarily limited by the distortion content as the signal frequency increases. Figure 2 shows the distortion characteristics of the SMP-04 versus frequency. It maintains less than 1% total harmonic distortion over a voiceband of 8kHz.

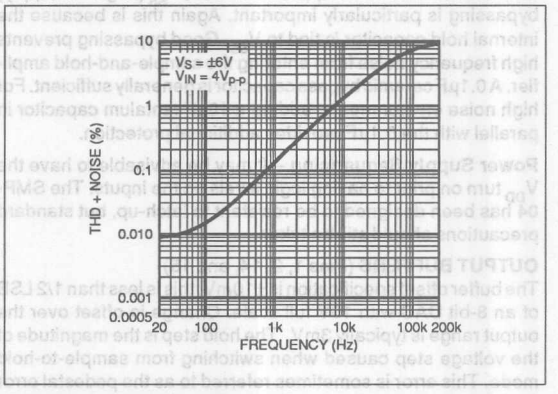

FIGURE 2: *THD+N vs. Frequency*

Sampled Data Dynamic Performance – In continuous sampled data applications such as voice digitization or communication circuits, it is important to analyze the spectral response of a sample-and-hold. Figures 1a and b show the SMP-04 sampling at a frequency of 86kHz with a 1.4V_{p-p} pure sine wave input of 20kHz and 8kHz respectively. The photos include the sampling carrier frequency as well as its multiplying frequencies. In the case of the 20kHz carrier frequency, the second harmonic measures 41dB down from the fundamental, because the second is dominant, the signal-to-noise ratio is –40.9dB. The 8kHz case produces an improved S/N performance of –48 dB.

In the V.32 and V.33 modem environment, where a 1.8kHz carrier signal frequency is applied to the SMP-04, Figure 3 compares the spectral responses of the SMP-04 under three different sampling frequencies of 14.4kHz, 9.6kHz and 7.2kHz. The signal-to-noise ratios measure to be 58.2dB, 59.3dB and 60dB respectively.

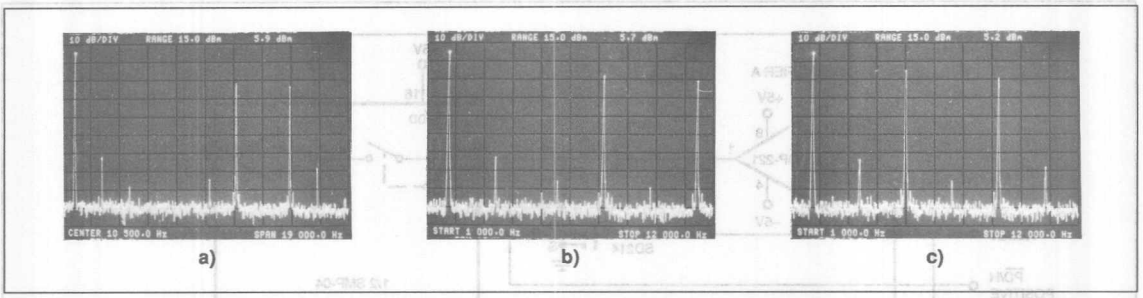

FIGURE 3: *SMP-04 spectral response with a 1.8kHz carrier frequency. (a) shows the sampling frequency at 14.4kHz; it exhibits a S/N ratio of 58.2dB. (b) shows a 59.3dB S/N at a sampling frequency of 8.6kHz. (c) shows a 60dB S/N at 7.2kHz.*

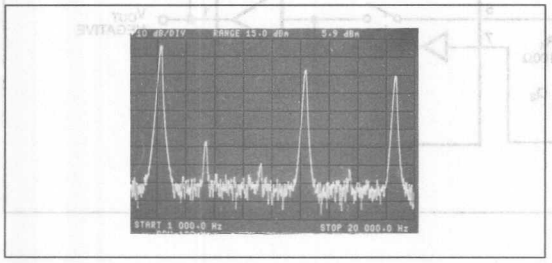

FIGURE 4: *SMP-04 spectral response with an input carrier frequency of 3kHz and the sampling frequency of 15.7kHz.*

Figure 4 depicts SMP-04's spectral response operating with voice frequency of 3kHz sampling at a 15.7kHz rate. Under this condition, the signal-to-noise measures 53dB.

4

APPLICATIONS

MULTIPLEXED QUAD DAC (Figure 5)

The SMP-04 can be used to demultiplex a single DAC converter's output into four separate analog outputs. The circuit is greatly simplified by using a voltage output DAC such as the DAC-8228. To minimize output voltage perturbation, 5µs should be allowed to settle to its final voltage before a sample signal is asserted. Each sample-and-hold amplifier must be refreshed every second or less in order to assure the droop does not exceed 10mV or 1/2 LSB.

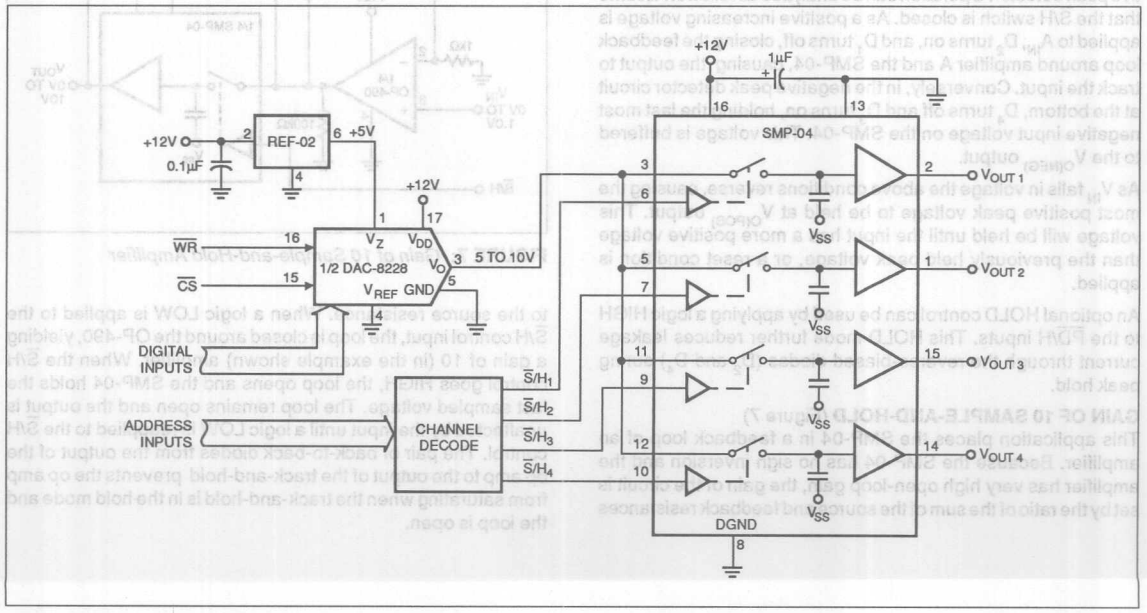

FIGURE 5: *Multiplexed Quad DAC*

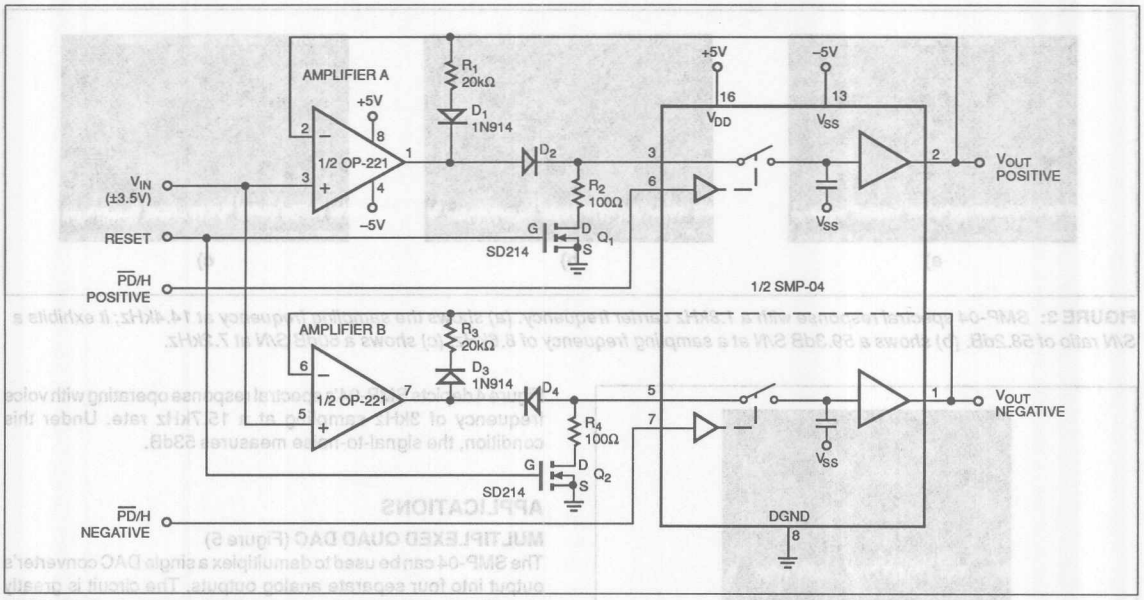

FIGURE 6: *Positive and Negative Peak Detector with Hold Control*

POSITIVE AND NEGATIVE PEAK DETECTOR WITH HOLD CONTROL (Figure 6)

In this application the top amplifier (amplifier A) is the positive peak detector and the bottom amplifier (amplifier B) is the negative peak detector. Operation can be analyzed as follows: Assume that the $\overline{S}$/H switch is closed. As a positive increasing voltage is applied to A_{IN}, D_2 turns on, and D_1 turns off, closing the feedback loop around amplifier A and the SMP-04, causing the output to track the input. Conversely, in the negative peak detector circuit at the bottom, D_4 turns off and D_3 turns on, holding the last most negative input voltage on the SMP-04. This voltage is buffered to the $V_{O(NEG)}$ output.

As V_{IN} falls in voltage the above conditions reverse, causing the most positive peak voltage to be held at $V_{O(POS)}$ output. This voltage will be held until the input has a more positive voltage than the previously held peak voltage, or a reset condition is applied.

An optional HOLD control can be used by applying a logic HIGH to the $\overline{PD}$/H inputs. This HOLD mode further reduces leakage current through the reverse-biased diodes (D_2 and D_4) during peak hold.

GAIN OF 10 SAMPLE-AND-HOLD (Figure 7)

This application places the SMP-04 in a feedback loop of an amplifier. Because the SMP-04 has no sign inversion and the amplifier has very high open-loop gain, the gain of the circuit is set by the ratio of the sum of the source and feedback resistances

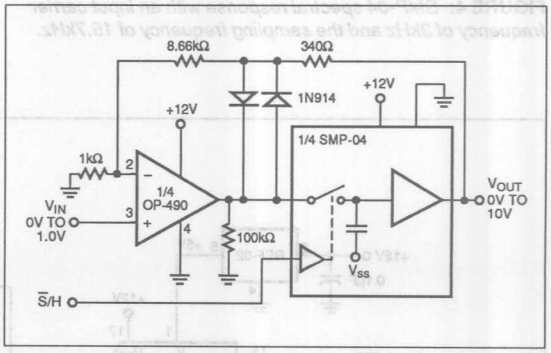

FIGURE 7: *Gain of 10 Sample-and-Hold Amplifier*

to the source resistance. When a logic LOW is applied to the $\overline{S}$/H control input, the loop is closed around the OP-490, yielding a gain of 10 (in the example shown) amplifier. When the $\overline{S}$/H control goes HIGH, the loop opens and the SMP-04 holds the last sampled voltage. The loop remains open and the output is unaffected by the input until a logic LOW is reapplied to the $\overline{S}$/H control. The pair of back-to-back diodes from the output of the op amp to the output of the track-and-hold prevents the op amp from saturating when the track-and-hold is in the hold mode and the loop is open.

SAMPLE AND DIFFERENCE AMPLIFIER (Figure 8)
This circuit uses two sample-and-holds to measure the voltage difference of a signal between two time points, t_1 and t_2. The sampled voltages are fed into the differential inputs of the AMP-02 instrumentation amplifier. A single resistor R_G sets the gain of this instrumentation amplifier. Using two of the SMP-04s in this application has the advantage of matched sample-and-hold performance, since they are both on the same chip.

SINGLE SUPPLY, SAMPLING, INSTRUMENTATION AMPLIFIER (Figure 9)
This application again uses two channels of the SMP-04 and an instrumentation amplifier to provide a sampled difference signal. The sample-and-hold signals in this circuit are tied together to sample at the same point in time. The other two parts of the SMP-04 are used as amplifiers by grounding their control lines so that they are always sampling. One section is used to drive a guard to the common-mode voltage and the other to generate a +6V reference to serve as an offset for single supply operation.

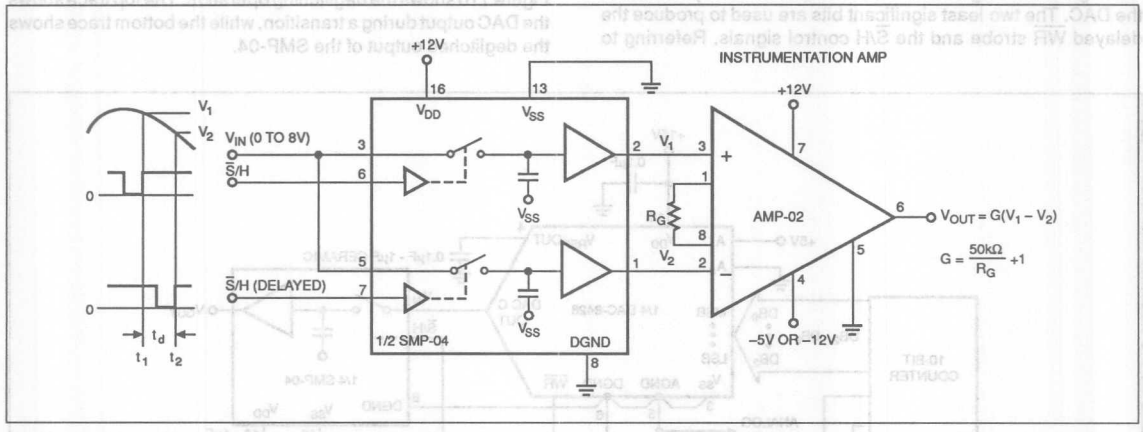

FIGURE 8: *Time Delta Sample-and-Difference Measurement*

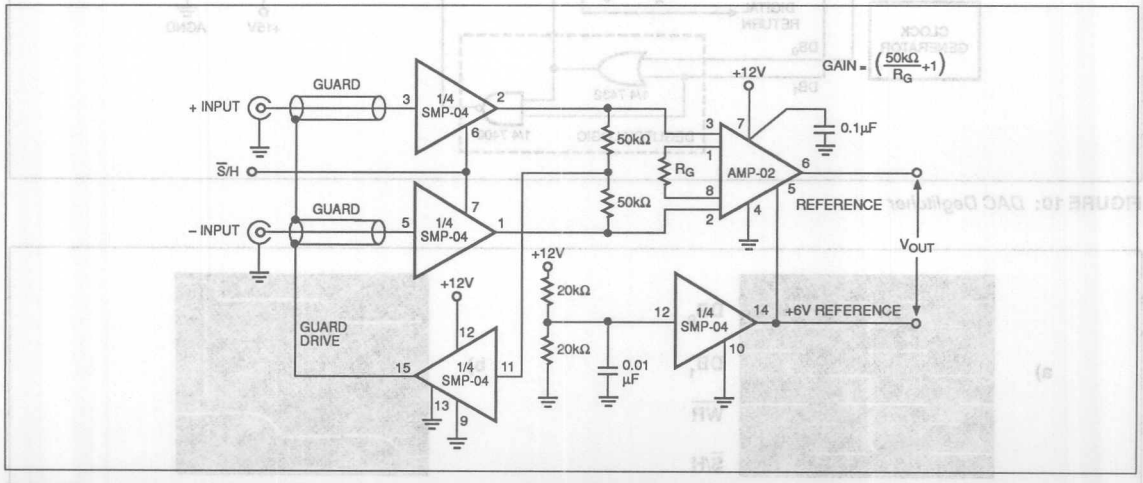

FIGURE 9: *+12V Single Supply Sampling Instrumentation Amplifier with Guard Drive*

Most D/A converters output an appreciable amount of glitch energy during a transition from one code to another. The glitch amplitude can range from several millivolts to hundreds of millivolts. This may become unacceptable in many applications. By selectively delaying the DAC's output transition, the SMP-04 can be used to smooth the output waveform. Figure 10 shows the schematic diagram of such a deglitcher circuit. Two simple logic gates (an OR and a NAND gate) provide the proper timing sequence for the DAC $\overline{WR}$ strobe and the $\overline{S}$/H control signal to the SMP-04. In this example a linear ramp signal is generated by feeding the most significant 8-bits of the 10-bit binary counter to the DAC. The two least significant bits are used to produce the delayed $\overline{WR}$ strobe and the $\overline{S}$/H control signals. Referring to the timing diagram, Figure 11a, the DAC's output changes on the falling edge, but the DAC output does not change yet until a $\overline{WR}$ strobe goes active. During this period, the SMP-04 is in a sample mode whose output tracks the DAC output. When $\overline{S}$/H goes HIGH, the current DAC output voltage is held by the SMP-04. After 1.2µs settling, the $\overline{WR}$ strobe goes LOW to allow the DAC output to change. Any glitch that occurs at the DAC output is effectively blocked by the SMP-04. As soon as the $\overline{WR}$ strobe goes HIGH, the digital data is latched; at the same time the $\overline{S}$/H goes LOW, allowing the SMP-04 to track to the new DAC output voltage.

Figure 11b shows the deglitching operation. The top trace shows the DAC output during a transition, while the bottom trace shows the deglitched output of the SMP-04.

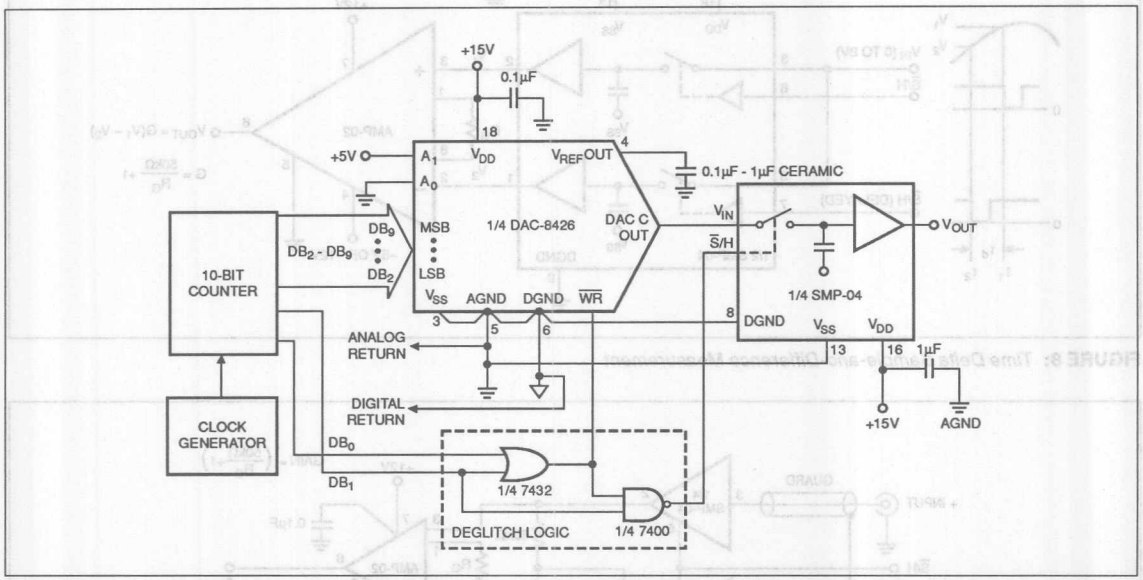

FIGURE 10: *DAC Deglitcher*

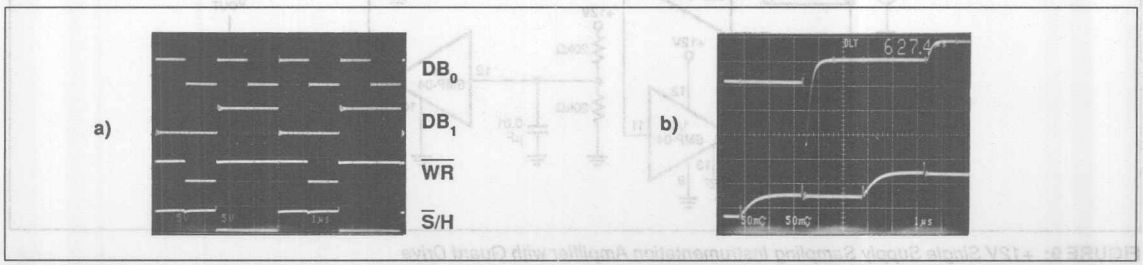

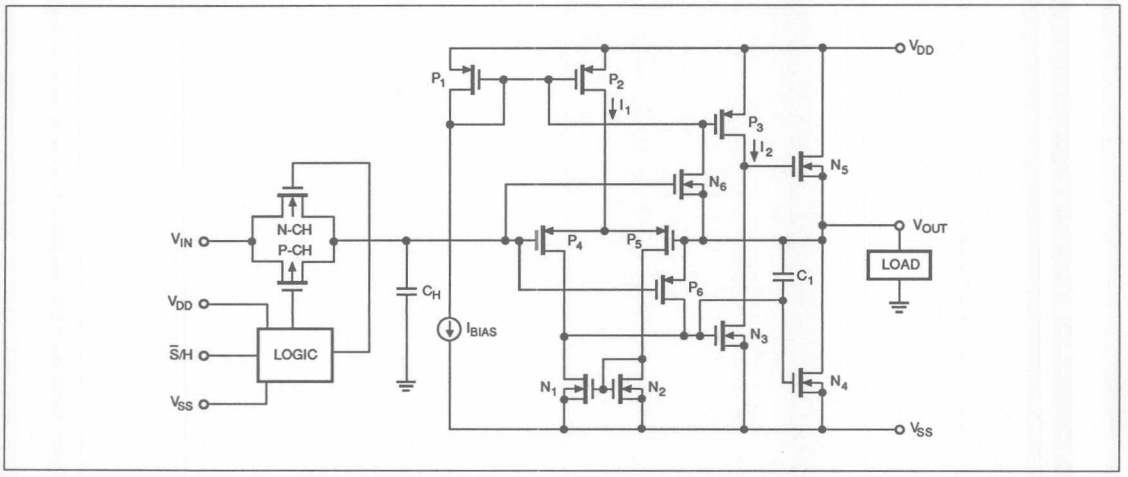

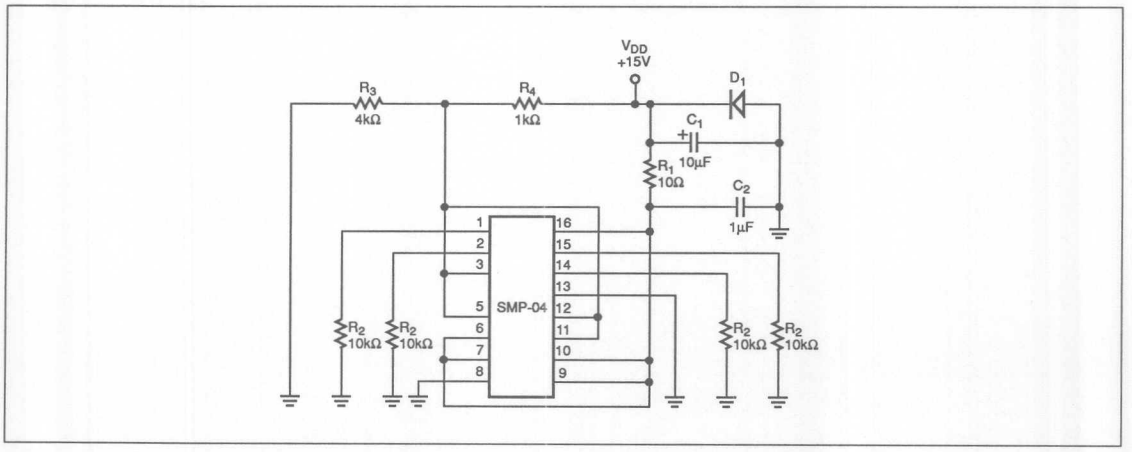

FIGURE 11: *(a) shows the logic timing of the deglitcher. The top two traces are the two least significant bits, DB_0 and DB_1, respectively. These are used to generate the $\overline{WR}$ and $\overline{S}$/H signals which are shown in the bottom two traces. (b) shows the typical glitch amplitude of a DAC (top trace) and the deglitched output of the AMP-04 (bottom trace).*

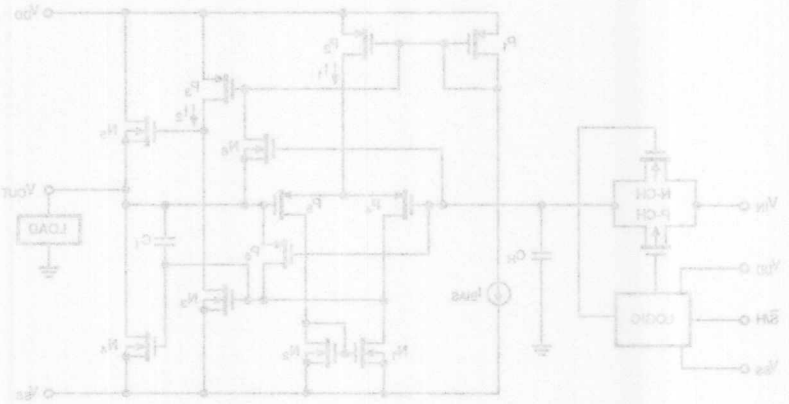

SIMPLIFIED SCHEMATIC

BURN-IN CIRCUIT

SIMPLIFIED SCHEMATIC

BURN-IN CIRCUIT

Octal Sample-and-Hold with Multiplexed Input

SMP-08

FEATURES

- Internal Hold Capacitors
- Low Droop Rate
- TTL/CMOS Compatible Logic Inputs
- Single or Dual Supply Operation
- Break-Before-Make Channel Addressing
- Compatible With CD4051 Pinout
- Low Cost

APPLICATIONS

- Multiple Path Timing Deskew for A.T.E.
- Memory Programmers
- Mass Flow/Process Control Systems
- Multichannel Data Acquisition Systems
- Robotics and Control Systems
- Medical and Analytical Instrumentation
- Event Analysis
- Stage Lighting Control

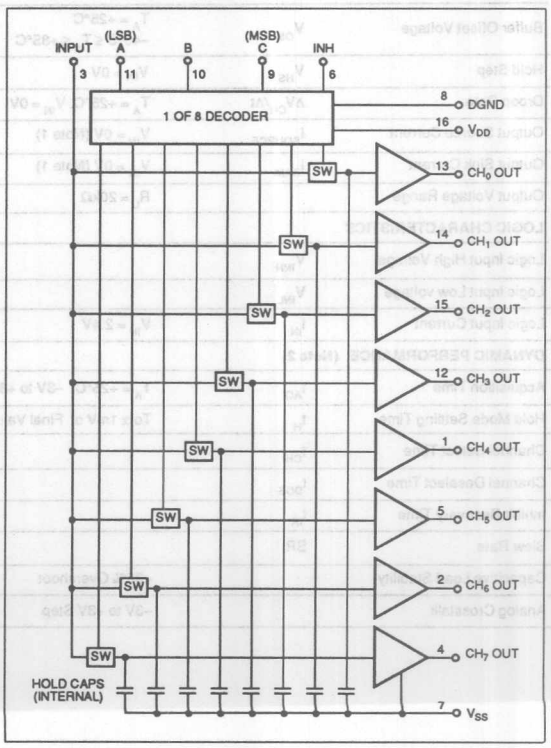
GENERAL DESCRIPTION



The SMP-08 is a monolithic octal sample-and-hold; it has eight internal buffer amplifiers, input multiplexer, and internal hold capacitors. It is manufactured in an advanced oxide isolated CMOS technology to obtain high accuracy, low droop rate, and fast acquisition time. The SMP-08 has a typical linearity error of only 0.01% and can accurately acquire a 10-bit input signal to ±1/2 LSB in less than seven microseconds. The SMP-08's output swing includes the negative supply in both single and dual supply operation.

The SMP-08 was specifically designed for systems that use a calibration cycle to adjust a multiple of system parameters. The low cost and high level of integration makes the SMP-08 ideal for calibration requirements that have previously required an ASIC, or high cost multiple D/A converters.

The SMP-08 is also ideally suited for a wide variety of sample-and-hold applications including amplifier offset or VCA gain adjustments. One or more SMP-08s can be used with single or multiple DACs to provide multiple set points within a system.

The SMP-08 offers significant cost and size reduction over discrete designs. It is available in a 16-pin hermetic or plastic DIP, or surface mount SOIC package.

FUNCTIONAL DIAGRAM

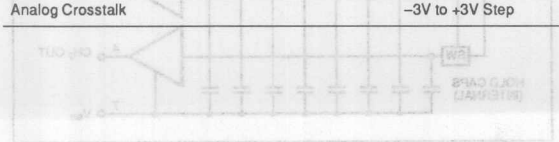
ABSOLUTE MAXIMUM RATINGS (Note 1)

V_{DD} to DGND ..... –0.3V, 17V
V_{DD} to V_{SS} ..... –0.3V, 17V
V_{LOGIC} to DGND ..... –0.3V, V_{DD}
V_{IN} to DGND ..... V_{SS}, V_{DD}
V_{OUT} to DGND ..... V_{SS}, V_{DD}
Analog Output Current ..... ±20mA
(Not short-circuit protected)
Operating Temperature Range
FP, FS ..... –40°C to +85°C
Junction Temperature ..... +150°C
Storage Temperature ..... –65°C to +150°C
Lead Temperature (Soldering, 60 sec) ..... +300°C



PACKAGE TYPE	Θ_{JA} (Note 2)	Θ_{JC}	UNITS
16-Pin Hermetic DIP (Q)	94	12	°C/W
16-Pin Plastic DIP (P)	76	33	°C/W
16-Pin SO (S)	92	27	°C/W

NOTES:
1. Absolute maximum ratings apply to both DICE and packaged parts, unless otherwise noted.
2. Θ_{JA} is specified for worst case mounting conditions, i.e., Θ_{JA} is specified for device in socket for CerDIP and P-DIP packages; Θ_{JA} is specified for device soldered to printed circuit board for SO package.

CAUTION:
1. Stresses above those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. This is a stress rating only and functional operation at or above this specification is not implied. Exposure to the above maximum rating conditions for extended periods may affect device reliability.
2. Digital inputs and outputs are protected; however, permanent damage may occur on unprotected units from high-energy electrostatic fields. Keep units in conductive foam or packaging at all times until ready to use. Use proper anti-static handling procedures.
3. Remove power before inserting or removing units from their sockets.

ELECTRICAL CHARACTERISTICS at V_{DD} = +5V, V_{SS} = –5V, DGND = 0V, R_L = No Load, T_A = –40°C to +85°C for SMP-08F, unless otherwise noted.

APPLICATIONS INFORMATION

The SMP-08, a multiplexed octal S/H, minimizes board space in systems requiring cycled calibration or an array of control voltages. When used in conjunction with a low cost 10-bit D/A, the SMP-08 can easily be integrated into microprocessor based systems. Since the SMP-08 features break-before-make switching and an internal decoder, no external logic is required. The SMP-08 has an internally regulated TTL supply so that TTL/CMOS compatibility is maintained over the full supply range. See Figure 1 for channel decode address information.

POWER SUPPLIES

The SMP-08 is capable of operating with either single or dual supplies, over a voltage range of 7 to 15 volts. Based on the supply voltages chosen, V_{DD} and V_{SS} establish the input and output voltage range, which is:

$(V_{SS} + 0.06V) \leq V_{OUT/IN} \leq (V_{DD} - 2V)$

Note that several specifications, including acquisition time, offset and output voltage compliance will degrade for supply voltages of less than 7V.

If split supplies are used, the negative supply should be bypassed with a 0.1µF capacitor in parallel with a 10µF to ground. The internal hold capacitors are connected to this supply pin and any noise will appear at the outputs.

In single supply applications, it is extremely important that the V_{SS} (negative supply) pin is connected to a clean ground. The hold capacitors are internally tied to the V_{SS} (negative) rail. Any ground noise or disturbance will directly couple to the output of the sample-and-hold, degrading the signal-to-noise performance. The analog and digital ground traces on the circuit board should be physically separated to reduce digital switching noise from entering the analog circuitry.

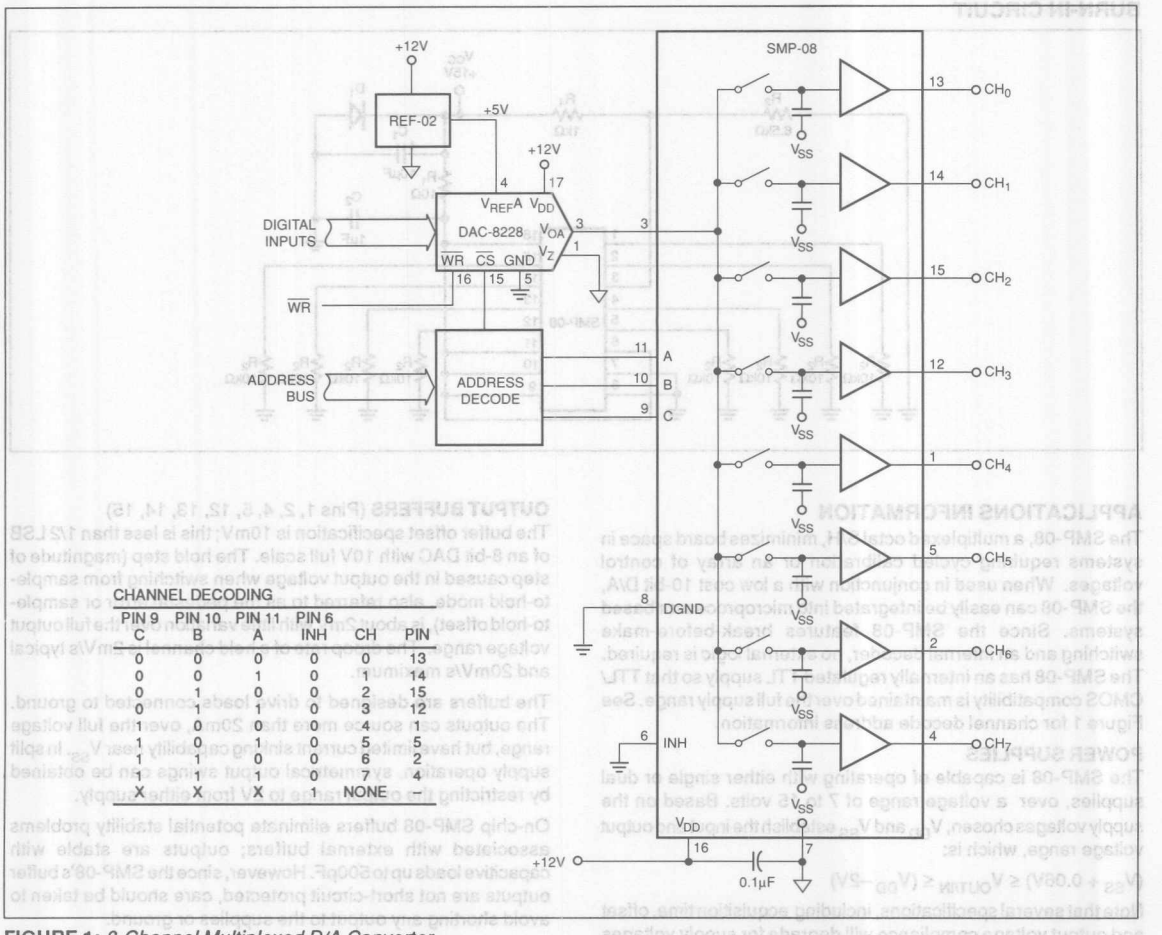
POWER SUPPLY SEQUENCING

V_{DD} should be applied to the SMP-08 before the logic input signals. The SMP-08 has been designed to be immune to latch-up, but standard precautions should still be taken.

OUTPUT BUFFERS (Pins 1, 2, 4, 5, 12, 13, 14, 15)

The buffer offset specification is 10mV; this is less than 1/2 LSB of an 8-bit DAC with 10V full scale. The hold step (magnitude of step caused in the output voltage when switching from sample-to-hold mode, also referred to as the pedestal error or sample-to-hold offset), is about 2mV with little variation over the full output voltage range. The droop rate of a held channel is 2mV/s typical and 20mV/s maximum.

The buffers are designed to drive loads connected to ground. The outputs can source more than 20mA, over the full voltage range, but have limited current sinking capability near V_{SS}. In split supply operation, symmetrical output swings can be obtained by restricting the output range to 2V from either supply.



On-chip SMP-08 buffers eliminate potential stability problems associated with external buffers; outputs are stable with capacitive loads up to 500pF. However, since the SMP-08's buffer outputs are not short-circuit protected, care should be taken to avoid shorting any output to the supplies or ground.

SIGNAL INPUT (Pin 3)

The signal input should be driven from a low impedance voltage source such as the output of an op amp. The op amp should have a high slew rate and fast settling time if the SMP-08's acquisition time characteristics are to be maintained. As with all CMOS devices, all input voltages should be kept within range of the supply rails ($V_{SS} \leq V_{IN} \leq V_{DD}$) to avoid the possibility of latch-up. If single supply operation is desired, op amps such as the OP-21, OP-80, or OP-90 that have input and output voltage compliances including ground, can be used to drive the inputs. Split supplies, such as ±7.5V, can be used with the SMP-08.

APPLICATION TIPS

All unused digital inputs should be connected to logic LOW and unused analog inputs connected to analog ground. For connector-driven analog inputs that may become temporarily disconnected, a resistor to V_{DD}, V_{SS} or analog ground should be used with a value ranging from 200kΩ to 1MΩ.

FIGURE 1: *8-Channel Multiplexed D/A Converter*

Do not apply signals to the SMP-08 with power off unless the input current is limited to less than 10mA.

TYPICAL APPLICATIONS

AN 8-CHANNEL MULTIPLEXED D/A CONVERTER

Figure 1 illustrates a typical multiplexing function of the SMP-08. It is used to sample-and-hold eight different output voltages corresponding to eight different digital codes from a D/A converter. The SMP-08's droop rate of 20mV/s requires a refresh once every 500ms, before the voltage drifts beyond 1/2 LSB accuracy (1 LSB of an 8-bit DAC is equivalent to 19.5mV, out of a full-scale voltage of 5V). For a 10-bit DAC, the refresh rate must be less than 120ms, and, for a 12-bit system, 31ms. This implementation is very cost-effective compared to using multiple DACs as the number of output channels increases.

FEATURES

SMP-10

- Low Droop Rate 5.0μV/ms
- Linearity Error 0.005%
- High Sample/Hold Current Ratio ..... 2×10^9

SMP-11

- Low Droop Rate Over Temperature 2400μV/ms
- High Sample/Hold Current Ratio ..... 1.7×10^8

BOTH SMP-10 AND SMP-11

- Fast Acquisition Time, 10V Step to 0.1% 3.5μs
- High Slew Rate 10V/μs
- Low Aperture Time 50ns
- Trimmed for Minimum Zero-Scale Error 0.45mV
- Feedthrough Attenuation Ratio 96dB
- Low Power Dissipation 160mW
- DTL, TTL & CMOS Compatible Logic Input
- HA-2420, HA-2425, SHM-IC-1, and AD583 Socket Compatible
- Available in Die Form

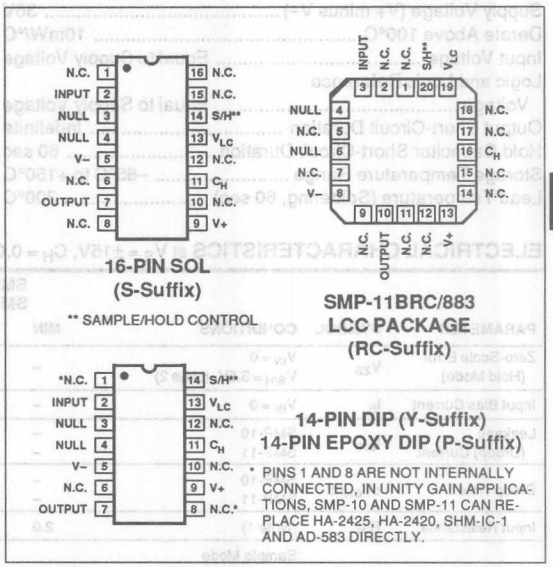
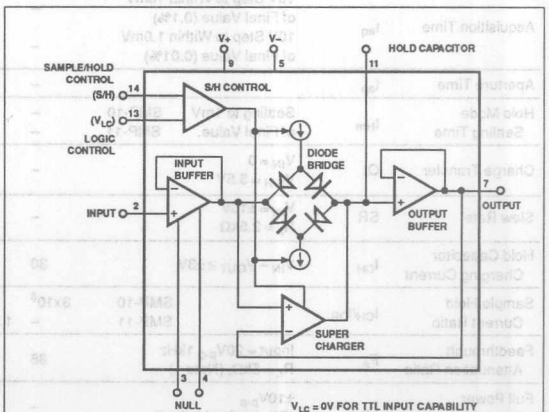
GENERAL DESCRIPTION

The SMP-10/11 are precision sample-and-hold amplifiers that provide the high accuracy, the low droop rate and the fast acquisition time required in data acquisition and signal processing systems. Both devices are essentially noninverting unity gain circuits consisting of two very high input impedance buffer amplifiers connected together by a diode bridge switch.



HIGH ACCURACY AND LOW DROOP RATE

The high input impedance and the low droop rates of the SMP-10 and the SMP-11 are achieved by using bipolar Darlington circuits and an ion implant process that creates "super beta" transistors.



The output buffer's input stage converts to a super beta Darlington configuration during the hold mode, which results in a very low droop rate with no penalty in acquisition time. The use of bipolar transistors achieves a low change in droop rate over the operating temperature range.

Manufactured under the following patents: 4,109,215 and 4,142,117.

GENERAL DESCRIPTION *Continued*

FAST ACQUISITION

A unique super charger provides up to 50mA of charging current to the hold capacitor, which results in smooth, fast charging with minimum noise. As the hold capacitor voltage nears its final value, the low current diode bridge controls the final settling time. This unique combination of linear functions in a monolithic circuit enables the system designer to achieve superior performance.

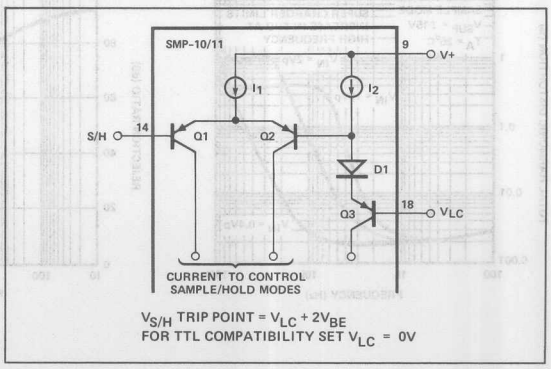
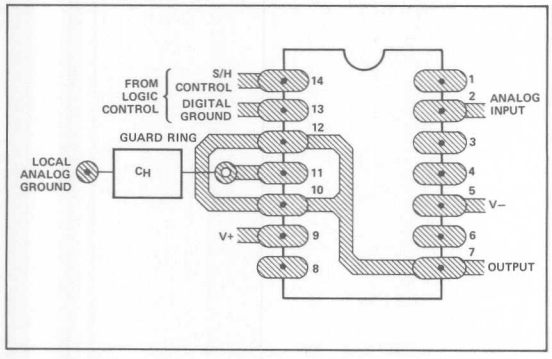
APPLICATIONS INFORMATION



During the null adjustment, the amplifier should be switched continuously between the "sample" and "hold" mode. The error should be adjusted to read zero when the unit is in the "hold" mode. In this way, both offset voltage errors and charge transfer errors are adjusted to zero.

As shown in the Figure, the sample/hold mode control is accomplished by steering the current (I_1) through Q1 or Q2, thus providing high-speed switching and a predictable logic threshold. For TTL and DTL interface, simply ground V_{LC} (Pin 13). For CMOS, HTL and HNIL interface, the appropriate

ZERO-SCALE NULL ADJUSTMENT



LOGIC CONTROL

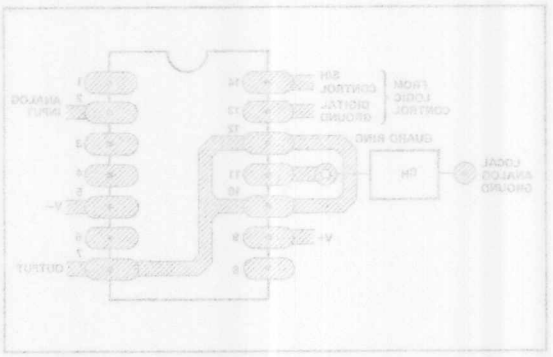
threshold voltage, allowing for 2 diode drops for D1 and V_{BE} of Q3, should be applied to V_{LC}.

For proper operation, the V_{LC} (logic control) must always be at least 3.5V below the positive supply and 2.0V above the negative supply.

Sample-and-hold control voltage (S/H) must always be at least 2.8V above the negative supply.

GUARDING AND GROUNDING LAYOUT

The use of a ground plane is strongly recommended to minimize ground path resistances. Separate analog and digital grounds should be used, and it is advisable to keep these two ground systems isolated until they are tied back to the common system ground. Digital currents should not flow back to the system ground through the analog ground path.



HOLD CAPACITOR RECOMMENDATIONS

The hold capacitor (C_H) acts as a memory element and also as a compensating capacitor for the sample-and-hold amplifier. For stable operation, a minimum value of 2000pF is recommended, with no limit set for the maximum value. The devices have been internally trimmed for C_H=5000pF. Other values of C_H will cause a zero-scale shift, which can be calculated from the following equation:

$$\Delta V_{ZS}(mV) = \frac{5\,(pC) \times 10^3}{C_H\,(pF)} - 1$$

The hold capacitor should have very high insulation resistance and low dielectric absorption. For temperatures below 85°C, polystyrene capacitors are recommended, while teflon capacitors are recommended for higher temperature applications.

FUNCTIONAL BLOCK DIAGRAM

GENERAL DESCRIPTION

The SMP-18 is a monolithic octal sample-and-hold; it has eight internal buffer amplifiers, input multiplexer, and internal hold capacitors. It is manufactured in an advanced oxide isolated CMOS technology to obtain high accuracy, low droop rate, and fast acquisition time. The SMP-18 has a typical linearity error of only 0.01% and can accurately acquire a 10-bit input signal to ±1/2 LSB in less than 2.5 microseconds. The SMP-18's output swing includes the negative supply in both single and dual supply operation.

The SMP-18 was specifically designed for systems that use a calibration cycle to adjust a multiple of system parameters. The low cost and high level of integration make the SMP-18 ideal for calibration requirements that have previously required an ASIC, or high cost multiple D/A converters.

The SMP-18 is also ideally suited for a wide variety of sample-and-hold applications including amplifier offset or VCA gain adjustments. One or more SMP-18s can be used with single or multiple DACs to provide multiple set points within a system.

The SMP-18 offers significant cost and size reduction over discrete designs. It is available in a 16-pin hermetic or plastic DIP or surface mount SOIC package. The SMP-18 is a higher speed direct replacement for the SMP-08.

ELECTRICAL CHARACTERISTICS (@ V_{DD} = +15 V, V_{SS} = −5 V, DGND = 0 V, R_L = No Load, T_A = −40°C to +85°C for SMP-18F, unless otherwise noted)

Parameter	Symbol	Conditions	Min	Typ	Max	Units
Linearity Error		−3 V ≤ V_{IN} ≤ +3 V		0.01		%
Buffer Offset Voltage	V_{OS}	T_A = +25°C, V_{IN} = 0 V		2.5	10	mV
		−40°C ≤ T_A ≤ +85°C, V_{IN} = 0 V		3.5	20	mV
Hold Step	V_{HS}	V_{IN} = 0 V		4	6	mV
Droop Rate	$\Delta V_{CH}/\Delta t$	T_A = +25°C, V_{IN} = 0 V		2	40	mV/s
Output Source Current	I_{SOURCE}	V_{IN} = 0 V[1]	1.2			mA
Output Sink Current	I_{SINK}	V_{IN} = 0 V[1]	0.5			mA

		$-40°C \le T_A \le +85°C$		8.0	10.0	mA

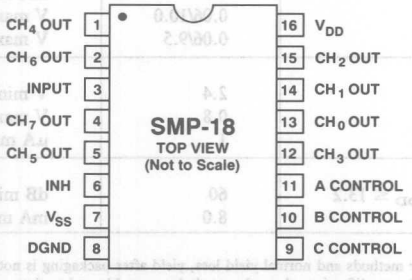
NOTES
[1]Outputs are capable of sinking and sourcing over 10 mA but offset is guaranteed at specified load levels.
[2]All input control signals are specified with $t_r = t_f = 5$ ns (10% to 90% of +5 V) and timed from a voltage level of 1.6 V.
[3]Slew rate is measured in the sample mode with a 0 to 10 V step from 20% to 80%.
Specifications subject to change without notice.

ABSOLUTE MAXIMUM RATINGS[1]

V_{DD} to DGND . . . . . −0.3 V, 17 V
V_{DD} to V_{SS} . . . . . −0.3 V, 17 V
V_{LOGIC} to DGND . . . . . −0.3 V, V_{DD}
V_{IN} to DGND . . . . . V_{SS}, V_{DD}
V_{OUT} to DGND . . . . . V_{SS}, V_{DD}
Analog Output Current . . . . . ±20 mA
(Not short-circuit protected)
Operating Temperature Range
FQ, FP, FS . . . . . −40°C to +85°C
Junction Temperature . . . . . +150°C
Storage Temperature . . . . . −65°C to +150°C
Lead Temperature (Soldering, 60 sec) . . . . . +300°C

Package Type	θ_{JA}[2]	θ_{JC}	Units
16-Pin Hermetic DIP (Q)	94	12	°C/W
16-Pin Plastic DIP (P)	76	33	°C/W
16-Pin SOIC (S)	92	27	°C/W

NOTES
1. Absolute maximum ratings apply to both DICE and packaged parts, unless otherwise noted.
2. θ_{JA} is specified for worst case mounting conditions, i.e., θ_{JA} is specified for device in socket for cerdip and plastic DIP packages; θ_{JA} is specified for device soldered to printed circuit board for SOIC package.



4

CAUTION

1. Stresses above those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. This is a stress rating only and functional operation at or above this specification is not implied. Exposure to the above maximum rating conditions for extended periods may affect device reliability.
2. Digital inputs and outputs are protected; however, permanent damage may occur on unprotected units from high-energy electrostatic fields. Keep units in conductive foam or packaging at all times until ready to use. Use proper antistatic handling procedures.
3. Remove power before inserting or removing units from their sockets.

APPLICATIONS INFORMATION

The SMP-18, a multiplexed octal S/H, minimizes board space in systems requiring cycled calibration or an array of control voltages. When used in conjunction with a low cost 10-bit D/A, the SMP-18 can easily be integrated into microprocessor based systems. Since the SMP-18 features break-before-make switching and an internal decoder, no external logic is required. The SMP-18 has an internally regulated TTL supply so that TTL/CMOS compatibility is maintained over the full supply range. See Figure 1 for channel decode address information.

POWER SUPPLIES

The SMP-18 is capable of operating with either single or dual supplies, over a voltage range of 7 to 15 volts. Based on the supply voltages chosen, V_{DD} and V_{SS} establish the output voltage range, which is:

$$(V_{SS} + 0.06\ V) \leq V_{OUT} \leq (V_{DD} - 2\ V)$$

Note that several specifications, including acquisition time, offset and output voltage, compliance will degrade for supply voltages of less than 7 V.

If split supplies are used, the negative supply should be bypassed with a 0.1 µF capacitor in parallel with a 10 µF to ground. The internal hold capacitors are connected to this supply pin and any noise will appear at the outputs.

In single supply applications, it is extremely important that the V_{SS} (negative supply) pin is connected to a clean ground. The hold capacitors are internally tied to the V_{SS} (negative) rail. Any ground noise or disturbance will directly couple to the output of the sample-and-hold, degrading the signal-to-noise performance. The analog and digital ground traces on the circuit board should be physically separated to reduce digital switching noise from entering the analog circuitry.

POWER SUPPLY SEQUENCING

V_{DD} should be applied to the SMP-18 before the logic input signals. The SMP-18 has been designed to be immune to latch-up, but standard precautions should still be taken.

OUTPUT BUFFERS (Pins 1, 2, 4, 5, 12, 13, 14, 15)

The buffer offset specification is 10 mV; this is less than 1/2 LSB of an 8-bit DAC with 10 V full scale. The hold step (magnitude of step caused in the output voltage when switching from sample-to-hold mode, also referred to as the pedestal error or sample-to-hold offset) is about 4 mV with little variation over the full output voltage range. The droop rate of a held channel is 2 mV/s typical and 40 mV/s maximum.

The buffers are designed to drive loads connected to ground. The outputs can source more than 20 mA, over the full voltage range, but have limited current sinking capability near V_{SS}. In split supply operation, symmetrical output swings can be obtained by restricting the output range to 2 V from either supply.

On-chip SMP-18 buffers eliminate potential stability problems associated with external buffers; outputs are stable with capacitive loads up to 500 pF. However, since the SMP-18's buffer outputs are not short circuit protected, care should be taken to avoid shorting any output to the supplies or ground.

SIGNAL INPUT (Pin 3)

The signal input should be driven from a low impedance voltage source such as the output of an op amp. The op amp should have a high slew rate and fast settling time if the SMP-18's acquisition time characteristics are to be maintained. As with all CMOS devices, all input voltages should be kept within range of the supply rails ($V_{SS} \leq V_{IN} \leq V_{DD}$) to avoid the possibility of latch-up. If single supply operation is desired, op amps such as the OP-21, OP-80, or OP-90 that have input and output voltage compliances including ground, can be used to drive the inputs. Split supplies, such as ±7.5 V, can be used with the SMP-18.

APPLICATION TIPS

All unused digital inputs should be connected to logic LOW. For analog inputs that may become temporarily disconnected, a resistor to V_{DD}, V_{SS} or analog ground should be used with a value ranging from 200 kΩ to 1 MΩ.

Do not apply signals to the SMP-18 with power off unless the input current is limited to less than 10 mA.

TYPICAL APPLICATIONS

An 8-Channel Multiplexed D/A Converter

Figure 1 illustrates a typical multiplexing function of the SMP-18. It is used to sample-and-hold eight different output voltages corresponding to eight different digital codes from a D/A converter. The SMP-18's droop rate of 40 mV/s requires a refresh once every 250 ms before the voltage drifts beyond 1/2 LSB accuracy (1 LSB of an 8-bit DAC is equivalent to 19.5 mV, out of a full-scale voltage of 5 V). For a 10-bit DAC, the refresh rate must be less than 60 ms, and for a 12-bit system, 15 ms. This implementation is very cost effective compared to using multiple DACs as the number of output channels increases.

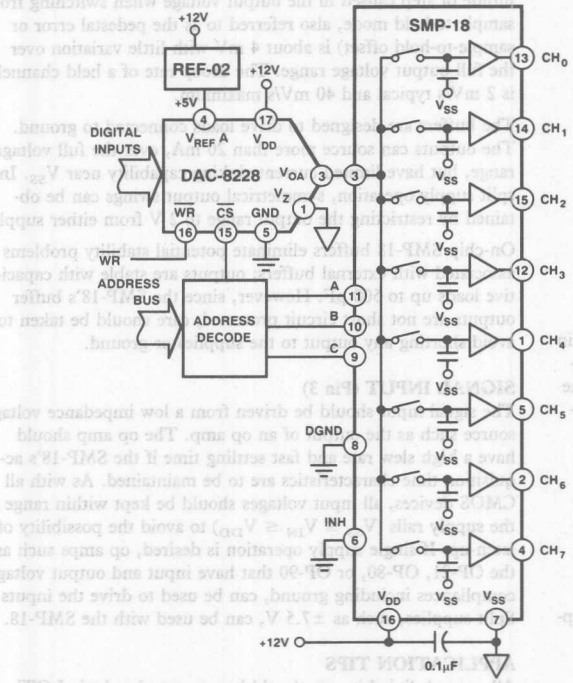

Figure 1. 8-Channel Multiplexed D/A Converter

Switches & Multiplexers

Solid-state analog multiplexers and switches have become an essential and ubiquitous component in the design of many electronic systems which require the ability to control and select a specified transmission path for an analog signal. These semiconductor devices are utilized in a wide range of applications including data acquisition, process control, instrumentation, video systems, and telephony systems. Analog Devices offers a complete line of monolithic analog multiplexers and switches in the commercial, industrial, and military grades which are well suited for these applications and environments.

In selecting analog multiplexers and switches, attention must be paid to several key specifications which affect a system's performance. The acquisition of an analog input signal within a specified time and error band is a primary concern affected by the on-channel resistance (R_{ON}) and the effective output capacitance ($C_{D(ON)}$) specifications in conjunction with the effective load impedance. The total output capacitance, consisting of both the multiplexer/switch output and load capacitance, will form an R-C constant with R_{ON}, thus affecting both the bandwidth and the settling time to within a specified error band. A low R_{ON} which remains relatively constant over the analog input range will ensure minimum signal attenuation and distortion. High crosstalk and off-isolation specifications prevent unselected signals from affecting the signal path, thus maintaining a high signal-to-noise ratio. Break-before-make switching ensures that no two channel inputs are simultaneously connected, thus avoiding potential damage to the input signal sources. Switching time and settling time will determine the maximum handling frequency of the multiplexer as determined by the sampling theorem. Voltage offset contributions from a multiplexer/switch are a result of the effective leakage currents flowing through R_{ON}, R_{SOURCE}, and R_{LOAD}.

Our product line can be categorized by the particular fabrication process employed into the following three distinct product families: CMOS, bipolar-JFET, and advanced bipolar (video). An understanding of the advantages and limitations of each of these processes is beneficial in selecting the best analog switch or multiplexer for a particular application. Devices fabricated on a CMOS or a bipolar-JFET process are bidirectional, and their input and output may be transposed, thus allowing a multiplexer to be configured as a demultiplexer.

The CMOS process utilizes both N- and P-channel MOSFETs in the design of the analog switch, digital control logic, and switch driver circuits. These bidirectional analog switches consist of a parallel combination of P- and N-channel MOSFETs, allowing the analog input voltage range to extend to the supply rails while maintaining a fairly constant ON channel resistance (R_{ON}). This process and architecture allow these devices to operate over a +5.0 V to +16.5 V single and dual supply range with the tradeoff being an increase in R_{ON} and switching time for decreasing supply ranges. Low power consumption and leakage currents are some of the intrinsic characteristics and advantages of CMOS processes. Various parasitic device capacitances in conjunction with the load resistance can adversely affect both crosstalk and off isolation, thus limiting the effective bandwidth of these devices to below 100 kHz for a 12-bit system.

Our current portfolio of CMOS multiplexers and switches are fabricated on either a low cost, enhanced LC^{2}MOS junction-isolated or a dielectrically isolated process. The LC^{2}MOS process features high breakdown voltages and very low parasitic capacitances which increase both the switching time and isolation. These junction-isolated devices are designed to restrict the incidence of SCR latch-up to conditions of excessive misuse. The dielectrically isolated process eliminates the parasitic junctions which cause SCR latch-up, thus extending the overvoltage protection at the analog ports to ±25 V above the power supplies while maintaining low R_{ON} and low leakage currents.

Analog multiplexers and switches fabricated on the bipolar-JFET process consist of high quality ion-implanted P-Channel JFET switches. The digital control logic and switch driver circuits for these switches consist of both bipolar and JFET devices. JFET switches tend to exhibit slightly lower R_{ON}, R_{ON} variation over the analog input range and parasitic device capacitance, resulting in improved bandwidth, isolation, crosstalk, and harmonic distortion specifications when compared to CMOS devices. The analog input range extends from the negative supply to approximately 4 volts ($V_{PINCH-OFF}$) below the positive supply. This radiation-hard process is not plagued by the SCR latch-up tendency, and is less susceptible to both ESD and analog over-voltage destruction, unlike traditional CMOS processes. The limitations of this process, when compared to CMOS, are an increase in power consumption, a lower analog input range, and a restricted power supply operating range.

The advanced bipolar process exhibits a minimum full-power bandwidth of 30 MHz and provides fast, wideband switching capabilities while maintaining crosstalk rejection of 75 dB at 10 MHz. As these specifications suggest, this process is best suited for video applications. Some other key specifications include gain flatness and tolerance, differential gain and phase, settling time, and input impedance. The AD9300 4 × 1 video multiplexer uses this process to achieve the high performance characteristics required for video applications which are unattainable through the other processes.

DEFINITIONS OF SPECIFICATIONS

Analog Input Leakage Current—$I_{S(OFF)}$
The algebraic sum of leakage currents into or out of an OFF-channel source input due to parasitic reverse-bias diode junctions.

Analog Output Leakage Current—I_{OUT} or $I_{D(OFF)}$
The algebraic sum of leakage currents into or out of an OFF-channel "D" output due to parasitic reverse-bias diode junctions.

Analog Output-to-Input Capacitance—$C_{DS(OFF)}$
The equivalent capacitance which shunts an open switch effectively between "S" and "D" output. This will determine a switch's isolation over frequency.

Analog Input/Output ON Capacitance—$C_{S(ON)}$, $C_{D(ON)}$
The capacitance between the analog "S" input or "D" output and ground with the channel ON.

Analog Input OFF Capacitance—$C_{S(OFF)}$
The capacitance between an analog "S" input and ground with the channel OFF.

Analog Output OFF Capacitance—$C_{D(OFF)}$
The capacitance between the analog "D" output and ground with the channel OFF. High frequency transmission and output settling time characteristics are highly influenced by this parameter in conjunction with R_{ON}.

Break-Before-Make Delay—(t_{OPEN})
The elapsed time between the turn-off of one analog input and the subsequent turn-on of another input as determined by the appropriate instantaneous change in the digital input code for both inputs measured between the outputs' 50% transition points.

Channel Capacitance—$C_{SS(OFF)}$, $C_{DD(OFF)}$
The capacitance between the "D" ("S") terminals of any two channels.

Charge Transfer—Q
Charge transfer appears as a voltage step (pedestal) on the output capacitance after switch turn-OFF due to charge coupling from the switch driver to the analog switch.

Crosstalk—CT
The proportionate amount of cross-coupling from an analog input channel to another output channel, expressed in dB. It is measured by driving the source of any channel with a specified input signal and observing the voltage which appears at the output with a specified load.

Digital Input Capacitance—C_{DIG} or C_{IN}
The capacitance between a digital input and ground.

Digital Input Current —(I_{INL} or I_{INH})
The current flowing into a digital input when a specified low level or high level voltage is applied to that input.

Digital Input Voltage—(V_{INL} and V_{INH})
The maximum threshold input voltage for Logic "0" and the minimum threshold input voltage for Logic "1."

Negative/Positive Voltage Supply—(V−, V_{SS} and V+, V_{DD})
The most negative and most positive voltage supply with respect to ground.

Off Isolation—$I_{SO(OFF)}$
The proportionate amount of a high frequency analog input signal which is coupled through the channel of an OFF device. This feedthrough is transmitted through the $C_{DS(OFF)}$ to a load comprised of $C_{D(OFF)}$ in parallel with an external load. Isolation generally decreases by 6 dB/octave with increasing frequency.

ON Resistance—R_{ON}
The series ON-channel resistance measured between "S" input and "D" output terminals under specified conditions.

ON Resistance Match—$R_{ON\ Match}$ or R_{ON} Between Switches
The channel-to-channel matching of ON resistance when channels are operated under identical conditions.

ON Resistance Variation—R_{ON} or R_{ON} vs. V_S
The variation of ON resistance produced by the specified analog input voltage change with a constant load current.

ON Channel Analog Leakage Current —$I_{D(ON)}$ + $I_{S(ON)}$ or $I_{OUT}-I_S$
Current loss (or gain) through an ON-channel resistance creating a voltage offset across the device. Specified as an absolute value since the direction of the current flow is unpredictable.

Output Enable Delay Time OFF—$t_{OFF(EN)}$
The required time for a multiplexer to disconnect the analog output from the selected analog input. It is measured from the 50% point of ENABLE input logic change to the time the output reaches 10% of the initial value.

Output Enable Delay Time ON—$t_{ON(EN)}$
The required time for a multiplexer to connect the analog output to the selected analog input. It is measured from the 50% point of ENABLE input logic change to the time the output reaches 90% of the final value.

Output OFF Switching Time—t_{OFF}
The time required to disconnect the analog output from the analog input. The time is measured from the 50% point of the logic input change to the time the output reaches 10% of the initial value.

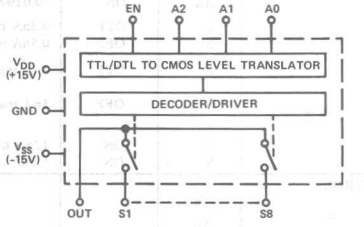
Output ON Switching Time—t_{ON}
The time required to connect the analog output to the analog input. The time is measured from the 50% of the logic input change to the time the output reaches 10% of the final value.

Output Settling Time—t_S
The elapsed time for the analog output to reach its final value within a specified error band after the corresponding digital input code has been changed. It is measured from the 50% point of the logic input change to the time the output reaches a final value within a specified error band.

Power Supply Rejection—PSSR
The ratio of the change in switch contact voltage (V_D) to the change in voltage supply (V+ or V−) that causes it.

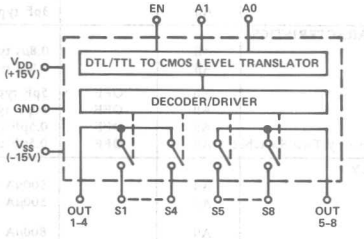
Switching Time— $t_{TRANSITION}$
The time required to switch and slew from one analog input channel to another analog input with a full-scale differential between inputs with a high impedance output load. The time is measured from the 50% point of the logic input change to the time the output reaches 80% of the final value.

Total Harmonic Distortion—THD
The ratio of the signal power at the fundamental frequency to the signal power of all harmonics observed at the switch output (V_D) with a pure sinusoid applied to the switch input (V_S).



CMOS 4/8 Channel Analog Multiplexers

AD7501/AD7502/AD7503



FEATURES
DTL/TTL/CMOS Direct Interface
Power Dissipation: 30μW
R_{ON}: 170Ω
Standard 16-Pin DIPs and 20-Terminal Surface Mount Packages

FUNCTIONAL BLOCK DIAGRAMS

AD7501/AD7503

AD7502

GENERAL DESCRIPTION

The AD7501 and AD7503 are monolithic CMOS, 8-channel analog multiplexers which switches one of 8 inputs to a common output depending on the state of three binary address lines and an "enable" input. The AD7503 is identical to the AD7501 except its "enable" logic is inverted. All digital inputs are TTL/DTL and CMOS logic compatible.

The AD7502 is a monolithic CMOS dual 4-channel analog multiplexer. Depending on the state of 2 binary address inputs and an "enable", it switches two output buses to two of 8 inputs.

AD7506

AD7507

GENERAL DESCRIPTION

The AD7506 is a monolithic CMOS 16-channel analog multiplexer packaged in a 28-pin DIP or a 28-terminal surface mount package. It switches a common output to one of 16 inputs, depending on the state of four address lines and an "enable." The AD7507 is identical to the AD7506 except it has two outputs switched to two of 16 inputs depending on three binary address states and an "enable."

GENERAL DESCRIPTION

The AD7510DI, AD7511DI and AD7512DI are a family of latch proof dielectrically isolated CMOS switches featuring overvoltage protection up to ±25V above the power supplies. These benefits are obtained without sacrificing the low "ON" resistance (75Ω) or low leakage current (500pA), the main features of an analog switch.

The AD7510DI and AD7511DI consist of four independent SPST analog switches packaged in either a 16-pin DIP or a 20-terminal surface mount package. They differ only in that the digital control logic is inverted. The AD7512DI has two independent SPDT switches packaged either in a 14-pin DIP or a 20-terminal surface mount package.

Very low power dissipation, overvoltage protection and TTL/CMOS direct interfacing are achieved by combining a unique circuit design and a dielectrically isolated CMOS process. Silicon nitride passivation ensures long term stability while monolithic construction provides reliability.

*Stresses above those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. This is a stress rating only and functional operation of the device at these or any other conditions above those indicated in the operational sections of this specification is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

CAUTION

ESD (electrostatic discharge) sensitive device. The digital control inputs are diode protected; however, permanent damage may occur on unconnected devices subject to high energy electrostatic fields. Unused devices must be stored in conductive foam or shunts. The protective foam should be discharged to the destination socket before devices are removed.

5

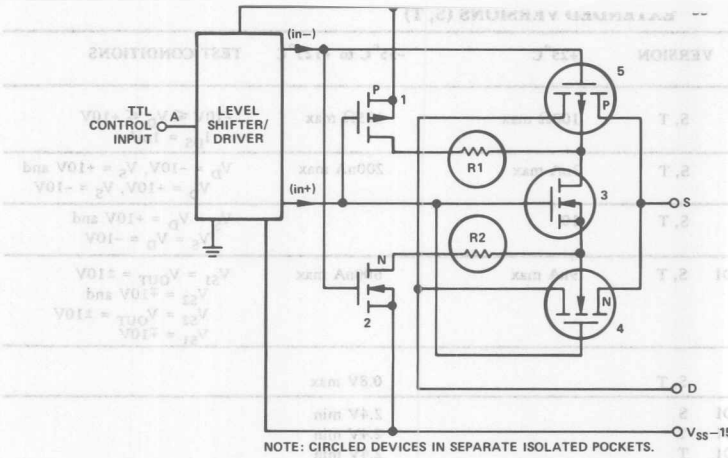

Figure 1. Typical Output Switch Circuitry of AD7510DI Series

CIRCUIT DESCRIPTION

CMOS devices make excellent analog switches; however, problems with overvoltage and latch-up phenomenon necessitated protection circuitry. These protection circuits, however, either caused degradation of important switch parameters such as R_{ON} or leakage, or provided only limited protection in the event of overvoltage.

The AD7510DI series switches utilize a dielectrically isolated CMOS fabrication process to eliminate the four-layer substrate found in junction-isolated CMOS, thus providing latch-free operation.

A typical switch channel is shown in Figure 2. The output switching element is comprised of device numbers 4 and 5. Operation is as follows: for an "ON" switch, (in+) is V_{DD} and (in−) is V_{SS} from the driver circuits. Device numbers 1 and 2 are "OFF" and number 3 in "ON". Hence, the backgates of the P- and N-channel output devices (numbers 4 and 5) are tied together and floating. The circled devices are located in separate dielectrically isolated pockets. Floating the output switch backgates with the signal input increases the effective threshold voltage for an applied analog signal, thus providing a flatter R_{ON} versus V_S response.

For an "OFF" switch, device number 3 is "OFF," and the backgates of devices 4 and 5 are tied through 1kΩ resistors (R1 and R2) to the respective supply voltages through the "ON" devices 1 and 2.

If a voltage is applied to the S or D (OUT) terminal which exceeds V_{DD} or V_{SS}, the S- or D-to-backgate diode is forward biased; however, R1 and R2 provide current limiting action to the supplies.

An equivalent circuit of the output switch element in Figure 3 shows that, indeed, the 1kΩ limiting resistors are in series with the backgates of the P- and N-channel output devices – *not* in series with the signal path between the S and D terminals.

It is possible to turn on an "OFF" switch by applying a voltage in excess of V_{DD} or V_{SS} to the S or D terminal. If a positive stress voltage is applied to the S or D terminal which exceeds V_{DD} by a threshold, then the P-channel (device 5) will turn on creating a low impedance path between the S and D terminals. A similar situation exists for negative stress voltages which exceed V_{SS}. In this case the N-channel provides the low impedance path between the S and D terminals. The limiting factor on the overvoltage protection is the power dissipation of the package and is ±20V continuous (or 20mA whichever occurs first) above the supply voltages.

TERMINOLOGY

R_{ON}	Ohmic resistance between terminals D and S.
R_{ON} Drift Match	Difference between the R_{ON} drift of any two switches.
R_{ON} Match	Difference between the R_{ON} of any two switches.
$I_D (I_S)_{OFF}$	Current at terminals D or S. This is a leakage current when the switch is "OFF".
$I_D (I_S)_{ON}$	Leakage current that flows from the closed switch into the body. (This leakage will show up as the difference between the current I_D going into the switch and the outgoing current I_S.)
$V_D (V_S)$	Analog voltage on terminal D (S).
$C_S (C_D)$	Capacitance between terminal S (D) and ground. (This capacitance is specified for the switch open and closed.)
C_{DS}	Capacitance between terminals D and S. (This will determine the switch isolation over frequency.)
$C_{DD} (C_{SS})$	Capacitance between terminals D (S) of any two switches. (This will determine the cross coupling between switches vs. frequency.)
t_{ON}	Delay time between the 50% points of the digital input and switch "ON" condition.
t_{OFF}	Delay time between the 50% points of the digital input and switch "OFF" condition.
$t_{TRANSITION}$	Delay time when switching from one address state to another.
V_{INL}	Maximum input voltage for a logic low.
V_{INH}	Minimum input voltage for a logic high.
$I_{INL} (I_{INH})$	Input current of the digital input.
C_{IN}	Input capacitance to ground of the digital input.
V_{DD}	Most positive voltage supply.
V_{SS}	Most negative voltage supply.
I_{DD}	Positive supply current.
I_{SS}	Negative supply current.

GENERAL DESCRIPTION

The AD7590DI, AD7591DI and AD7592DI are a family of protected (latch-proof) dielectrically isolated CMOS switches featuring overvoltage protection up to ±25V above the power supplies. Microprocessor interfacing is facilitated by the provision of on-chip data latches.

The AD7590DI and AD7591DI consist of four independent SPST analog switches packaged in a 16-pin DIP. They differ only in that the switch control logic is inverted. The AD7592DI has two independent SPDT switches packaged in a 14-pin DIP.

NOTES
[1]100% tested.
[2]Guaranteed, not production tested.
[3]Typical values for information only, not subject to test.
[4]Inputs are MOS gates typical current less than 10nA.
Specifications subject to change without notice.

TIMING AND CONTROL SEQUENCE

Figure 1 shows the timing sequence for latching the switch address inputs. The latches are level sensitive and, therefore, while $\overline{WR}$ is held low the latches are transparent and the switches respond to the address inputs. The digital inputs are latched on the rising edge of $\overline{WR}$.

NOTE: All digital input signals rise and fall times measured from 10% to 90% of 3V. $t_R = t_F = 20ns$.

CAUTION:
ESD (electrostatic discharge) sensitive device. The digital control inputs are diode protected; however, permanent damage may occur on unconnected devices subject to high energy electrostatic fields. Unused devices must be stored in conductive foam or shunts. The protective foam should be discharged to the destination socket before devices are inserted.

PIN CONFIGURATIONS

NOTE: CIRCLED DEVICES IN SEPARATE ISOLATED POCKETS.

Figure 2. Typical Output Switch Circuitry of AD7590DI Series

CIRCUIT DESCRIPTION

CMOS devices make excellent analog switches; however, problems with overvoltage and latch-up phenomenon necessitated protection circuitry. These protection circuits, however, either caused degradation of important switch parameters such as R_{ON} or leakage, or provided only limited protection in the event of overvoltage.

The AD7590DI series switches utilize a dielectrically-isolated CMOS fabrication process to eliminate the four-layer substrate found in junction-isolated CMOS, thus providing latch-free operation.

A typical switch channel is shown in Figure 2. The output switching element is comprised of device numbers 4 and 5. Operation is as follows: for an "ON" switch, (in+) is V_{DD} and (in−) is V_{SS} from the driver circuits. Device numbers 1 and 2 are "OFF" and number 3 in "ON". Hence, the backgates of the P- and N-channel output devices (numbers 4 and 5) are tied together and floating. The circled devices are located in separate dielectrically isolated pockets. Floating the output switch backgates with the signal input increases the effective threshold voltage for an applied analog signal, thus providing a flatter R_{ON} versus V_S response.

For an "OFF" switch, device number 3 is "OFF," and the backgates of devices 4 and 5 are tied through 1kΩ resistors (R1 and R2) to the respective supply voltages through the "ON" devices 1 and 2.

If a voltage is applied to the S or D (OUT) terminal which exceeds V_{DD} or V_{SS}, the S- or D-to-backgate diode is forward biased; however, R1 and R2 provide current limiting action to the supplies.

An equivalent circuit of the output switch element in Figure 3 shows that, indeed, the 1kΩ limiting resistors are in series with the backgates of the P- and N-channel output devices – *not* in series with the signal path between the S and D terminals.

It is possible to turn on an "OFF" switch by applying a voltage in excess of V_{DD} or V_{SS} to the S or D terminal. If a positive stress voltage is applied to the S or D terminal which exceeds V_{DD} by a threshold, then the P-channel (device 5) will turn on creating a low impedance path between the S and D terminals. A similar situation exists for negative stress voltages which exceed V_{SS}. In this case the N-channel provides the low impedance path between the S and D terminals. The limiting factor on the overvoltage protection is the power dissipation of the package and is ±20V continuous (or 20mA whichever occurs first) above the supply voltages.

4 × 1 Wideband Video Multiplexer

AD9300

FEATURES
- 34MHz Full Power Bandwidth
- ±0.1dB Gain Flatness to 8MHz
- 72dB Crosstalk Rejection @ 10MHz
- 0.03°/0.01% Differential Phase/Gain
- Cascadable for Switch Matrices
- MIL-STD-883 Compliant Versions Available

APPLICATIONS
- Video Routing
- Medical Imaging
- Electro-Optics
- ECM Systems
- Radar Systems
- Data Acquisition

FUNCTIONAL BLOCK DIAGRAM

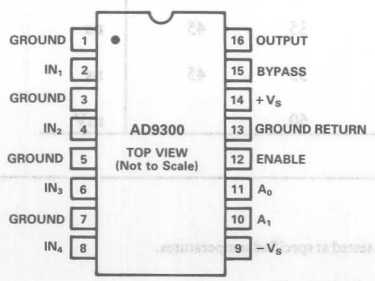
GENERAL DESCRIPTION

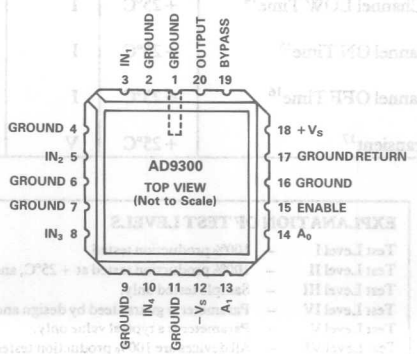
The AD9300 is a monolithic high-speed video signal multiplexer useable in a wide variety of applications.

Its four channels of video input signals can be randomly switched at megahertz rates to the single output. In addition, multiple devices can be configured in either parallel or cascade arrangements to form switch matrices. This flexibility in using the AD9300 is possible because the output of the device is in a high-impedance state when the chip is not enabled; when the chip is enabled, the unit acts as a buffer with a high input impedance and low output impedance.



An advanced bipolar process provides fast, wideband switching capabilities while maintaining crosstalk rejection of 72dB at 10MHz. Full power bandwidth is a minimum 27MHz. The device can be operated from ±10V to ±15V power supplies.

The AD9300K is available in a 16-pin ceramic DIP and a 20-pin PLCC and is designed to operate over the commercial temperature range of 0 to +70°C. The AD9300TQ is a hermetic 16-pin ceramic DIP for military temperature range (−55°C to +125°C) applications. This part is also available processed to MIL-STD-883. The AD9300 is available in a 20-pin LCC as the model AD9300TE, which operates over a temperature range of −55°C to +125°C.



The AD9300 Video Multiplexer is available in versions compliant with MIL-STD-883. Refer to the Analog Devices *Military Products Databook* or current AD9300/883B data sheet for detailed specifications.

EXPLANATION OF TEST LEVELS

Test Level I – 100% production tested.
Test Level II – 100% production tested at + 25°C, and sample tested at specified temperatures.
Test Level III – Sample tested only.
Test Level IV – Parameter is guaranteed by design and characterization testing.
Test Level V – Parameter is a typical value only.
Test Level VI – All devices are 100% production tested at + 25°C. 100% production tested at temperature extremes for military temperature devices; sample tested at temperature extremes for commercial/industrial devices.

Parameter (Conditions)	Temp	Test Level	COMMERCIAL 0°C to +70°C AD9300KQ/KP Min	Typ	Max	Units

NOTES
[1]Permanent damage may occur if any one absolute maximum rating is exceeded. Functional operation is not implied, and device reliability may be impaired by exposure to higher-than-recommended voltages for extended periods of time.
[2]Measured at extremes of temperature range.
[3]Measured as slope of V_{OUT} versus V_{IN} with $V_{IN} = \pm 1V$.
[4]Measured as worst deviation from end-point fit with $V_{IN} = \pm 1V$.
[5]Full Power Bandwith (FPBW) based on Slew Rate (SR). FPBW = $SR/2\pi V_{PEAK}$
[6]Measured between 20% and 80% transition points of ±1V output.
[7]T-Step = Sin^2X Step, when Step between 0V and +700mV points has 10%-to-90% risetime = 125ns.
[8]Measured with a pulse input having slew rate >250V/μs.
[9]Measured at output between 0.28Vdc and 1.0Vdc with V_{IN} = 284mV p–p at 3.58MHz and 4.43MHz.
[10]This specification is critically dependent on circuit layout. Value shown is measured with selected channel grounded and 10MHz 2V p–p signal applied to remaining three channels. If selected channel is grounded through 75Ω, value is approximately 6dB higher.
[11]This specification is critically dependent on circuit layout. Value shown is measured with selected channel grounded and 10MHz 2V p–p signal applied to one other channel. If selected channel is grounded through 75Ω, value is approximately 6dB higher. Minimum specification in ( ) applies to DIPs.
[12]Consult system timing diagram.
[13]Measured from address change to 90% point of −2V to +2V output LOW-to-HIGH transition.
[14]Measured from address change to 90% point of +2V to −2V output HIGH-to-LOW transition.
[15]Measured from 50% transition point of ENABLE input to 90% transition of 0V to −2V and 0V to +2V output.
[16]Measured from 50% transition point of ENABLE input to 10% transition of +2V to 0V and −2V to 0V output.
[17]Measured while switching between two grounded channels.
[18]Maximum power dissipation is a package-dependent parameter related to the following typical thermal impedances:
16-Pin Ceramic θ_{JA} = 87°C/W; θ_{JC} = 25°C/W
20-Pin LCC θ_{JA} = 74°C/W; θ_{JC} = 10°C/W
20-Pin PLCC θ_{JA} = 71°C/W; θ_{JC} = 26°C/W

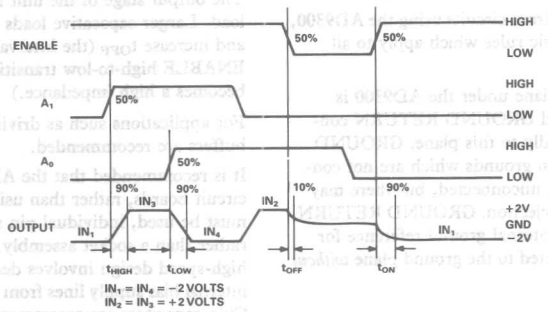
MECHANICAL INFORMATION



Die Dimensions	84 × 104 × 18 (max) mils
Pad Dimensions	4 × 4 (min) mils
Metalization	Aluminum
Backing	None
Substrate Potential	$-V_S$
Passivation	Oxynitride
Die Attach	Gold Eutectic
Bond Wire	1.25 mil, Aluminum; Ultrasonic Bonding or 1 mil, Gold; Gold Ball Bonding

FUNCTIONAL DESCRIPTION

$IN_1 - IN_4$	Four analog input channels.
GROUND	Analog input shielding grounds, not internally connected. Connect each to external low-impedance ground as close to device as possible.
A_0	One of two TTL decode control lines required for channel selection. See Logic Truth Table.
A_1	One of two TTL decode control lines required for channel selection. See Logic Truth Table.
ENABLE	TTL-compatible chip enable. In enabled mode (logic HIGH), output signal tracks selected input channel; in disabled mode (logic LOW), output is high impedance and no signal appears at output.
$-V_S$	Negative supply voltage; nominally −10V dc to −15V dc.
$+V_S$	Positive supply voltage; nominally +10V dc to +15V dc.
OUTPUT	Analog output. Tracks selected input channel when enabled.
BYPASS	Bypass terminal for internal bias line; must be decoupled externally to ground through 0.1µF capacitor.
GROUND RETURN	Analog signal and power supply ground return.

LOGIC TRUTH TABLE

ENABLE	A_1	A_0	OUTPUT
0	X	X	High Z

1	0	1	IN_2
1	1	0	IN_3
1	1	1	IN_4

AD9300 Timing

THEORY OF OPERATION

Refer to the functional block diagram of the AD9300.

As shown on the drawing, this diagram is based on the pinouts of the DIP packaging of the models AD9300KQ and AD9300TQ. The AD9300KP and AD9300TE are packaged in 20-pin surface mount packages. The extra pins are used for ground connections; the theory of operation remains the same.

The AD9300 Video Multiplexer allows the user to connect any one of four analog input channels ($IN_1 - IN_4$) to the output of the device, and to switch between channels at megahertz rates.

The input channel which is connected to the output is determined by a 2-bit TTL digital code applied to A_0 and A_1. The selected input will not appear at the output unless a digital "1" is also applied to the ENABLE input pin; unless the output is enabled, it is a high impedance. Necessary combinations to accomplish channel selection are shown in the Logic Truth Table.

Bipolar construction used in the AD9300 insures that the input impedance of the device remains high, and will not vary with power supply voltages. This characteristic makes the AD9300, in effect, a switchable-input buffer. An on-board bias network makes the performance of the AD9300 independent of applied supply voltages, which can have any nominal value from ±10V dc to ±15V dc.

Although the primary application for the AD9300 is the routing of video signals, the harmonic and dynamic attributes of the device make it appropriate for other applications. The AD9300 has exceptional performance when switching video signals, but can also be used for switching other analog signals requiring greater dynamic range and/or precision than those in video.

As shown in Figure 1, Input and Output Equivalent Circuits, each analog input is connected to the base of a bipolar transistor. If Channel 1 is selected, a current switch is closed and routes current through the input transistor for Channel 1.

If Channel 2 is then selected by the digital inputs, the current switch for Channel 1 is opened and the current switch for Channel 2 is closed. This causes current to be routed away from the Channel 1 transistor and into the Channel 2 input transistor. Whenever a channel's input device is carrying current, the analog input applied to that channel is passed to the output stage.

The operation of the output stage is similar to that of the input stages. Whenever the output stage is enabled with a HIGH digital "1" signal at the ENABLE pin, the output transistor will carry current and pass the selected analog input.

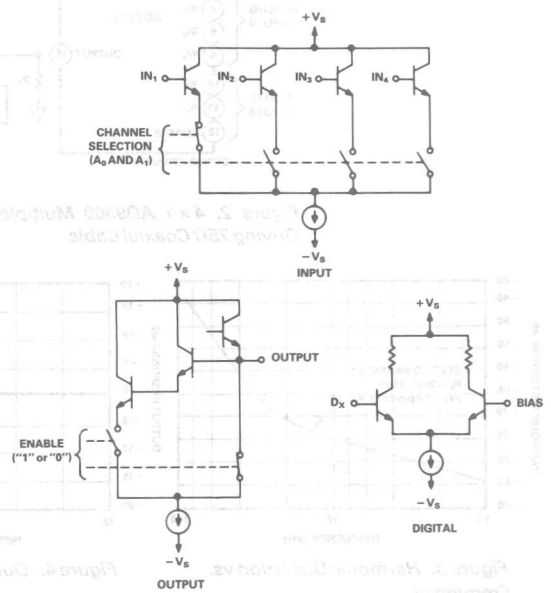

Figure 1. Input and Output Equivalent Circuits

When the output stage is disabled (by virtue of the ENABLE pin being driven LOW with a digital "0"), the output current switch is opened. This routes the current to other circuits within the AD9300 which keep the output transistor biased "off". These circuits require approximately 1μA of bias current from the load connected to the output of the multiplexer. In the absence of a terminating load and the resulting dc bias, the output of the AD9300 "floats" at −2.5V.

In summary, when the AD9300 is enabled by the ENABLE pin being driven HIGH with a digital "1", the selected analog input channel acts as a buffer for the input; and the output of the multiplexer is a low impedance. When the AD9300 is disabled with a digital "0" LOW signal, the selected channel acts as an open switch for the input; and the output of the unit becomes a high impedance. This characteristic allows the user to wire-or several AD9300 Analog Multiplexers together to form switch matrices.

AD9300 APPLICATIONS

To ensure optimum performance from circuits using the AD9300, it is important to follow a few basic rules which apply to all high-speed devices.

A large, low-impedance ground plane under the AD9300 is critical. Generally, GROUND and GROUND RETURN connections should be connected solidly to this plane. GROUND pin connections are signal isolation grounds which are not connected internally; they can be left unconnected, but there may be some degradation in crosstalk rejection. GROUND RETURN, on the other hand, serves as the internal ground reference for the AD9300 and should be connected to the ground plane *without exception*.

The output stage of the unit is capable of driving a 2kΩ‖10pF load. Larger capacative loads may limit full power bandwidth and increase t_{OFF} (the interval between the 50% point of the ENABLE high-to-low transition and the instant the output becomes a high impedance.)

For applications such as driving cables (See Figure 2), output buffers are recommended.

It is recommended that the AD9300 be soldered directly into circuit boards, rather than using socket assemblies. If sockets must be used, individual pin sockets are the preferred choice, rather than a socket assembly. A second requirement for proper high-speed design involves decoupling the power supply and internal bias supply lines from ground to improve noise immunity. Chip capacitors are recommended for connecting 0.1μF and 0.01μF capacitors between ground and the $\pm V_S$ supplies (Pins 9 and 14), and the BYPASS connection (Pin 15).

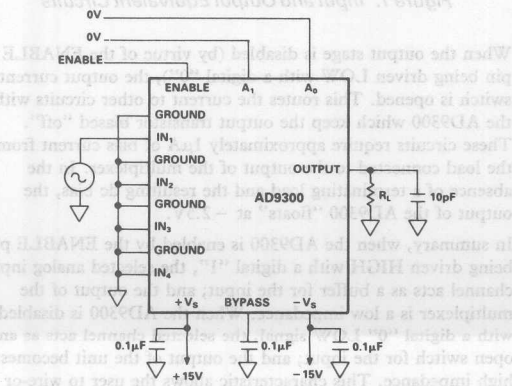

Figure 6. Test Circuit for Harmonic Distortion, Pulse Response, T-Step Response and Disable Characteristics

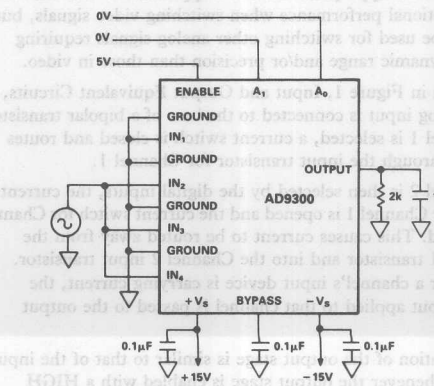

Figure 7. Crosstalk Rejection Test Circuit

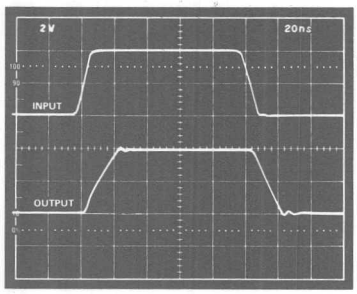

Figure 8. Pulse Response

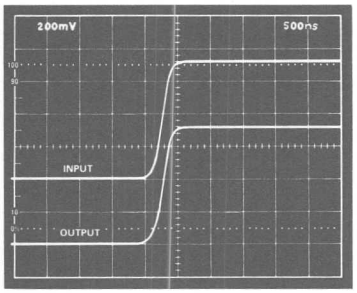

Figure 9. T-Step Response

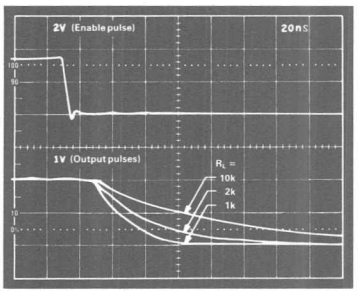

Figure 10. Enable to Channel "Off" Response

CROSSPOINT CIRCUIT APPLICATIONS

Four AD9300 multiplexers can be used to implement an 8×2 crosspoint, as shown in Figure 11. The circuit is modular in concept, with each pair of multiplexers (#1 and #2; #3 and #4) forming an 8×1 crosspoint. When the inputs to all four units are connected as shown, the result is an 8×2 crosspoint circuit.

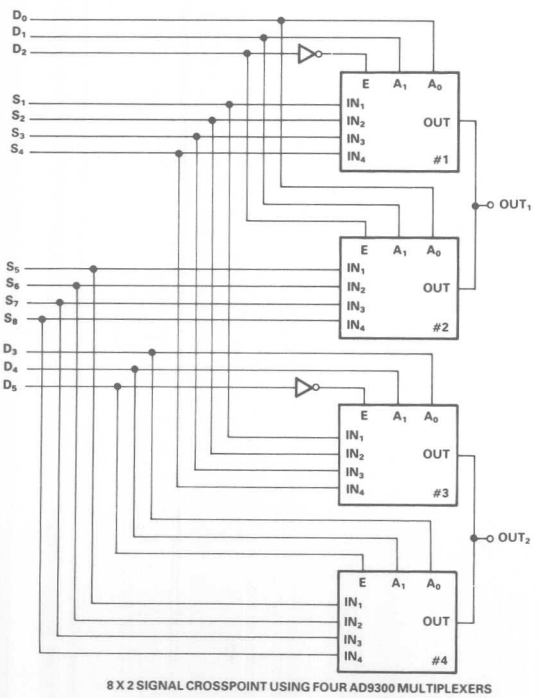

Figure 11. 8×2 Signal Crosspoint Using Four AD9300 Multiplexers

The truth table describes the relationships among the digital inputs (D_0 – D_5) and the analog inputs (S_1 – S_8); and which signal input is selected at the outputs (OUT_1 and OUT_2). The number of crosspoint modules that can be connected in parallel is limited by the drive capabilities of the input signal sources. High input impedance (3MΩ) and low input capacitance (2pF) of the AD9300 help minimize this limitation.

8 × 2 Crosspoint Truth Table

D_2 or D_5	D_1 or D_4	D_0 or D_3	OUT_1 or OUT_2
0	0	0	S_1
0	0	1	S_2
0	1	0	S_3
0	1	1	S_4
1	0	0	S_5
1	0	1	S_6
1	1	0	S_7
1	1	1	S_8

Adding to the number of inputs applied to each crosspoint module is simply a matter of adding AD9300 multiplexers in parallel to the module. Eight devices connected in parallel result in a 32×1 crosspoint which can be used with input signals having 30MHz bandwidth and 1V peak-to-peak amplitude. Even more AD9300 units can be added if input signal amplitude and/or bandwidth are reduced; if they are not, distortion of the output signals can result.

When an AD9300 is enabled, its low output impedance causes the "off" isolation of disabled parallel devices to be greater than the crosstalk rejection of a single unit.

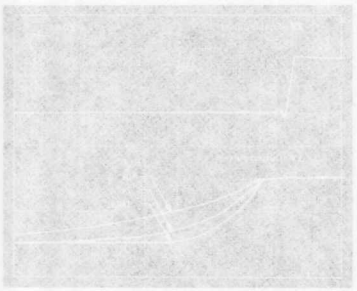

Figure 8. Pulse Response

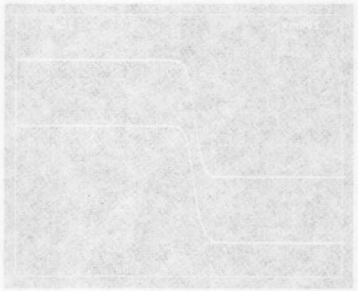

Figure 9. T-Step Response

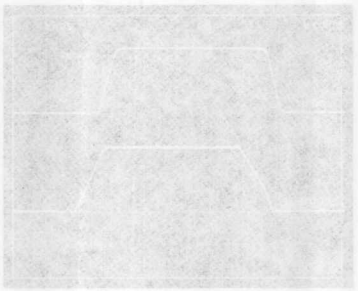

Figure 10. Enable to Channel "Off" Response

CROSSPOINT CIRCUIT APPLICATIONS

Four AD9300 multiplexers can be used to implement an 8 × 2 crosspoint, as shown in Figure 11. The circuit is modular in concept, with each pair of multiplexers (#1 and #2; #3 and #4) forming an 8 × 1 crosspoint. When the inputs to all four units are connected as shown, the result is an 8 × 2 crosspoint circuit.

Figure 11. 8 × 2 Signal Crosspoint Using Four AD9300 Multiplexers

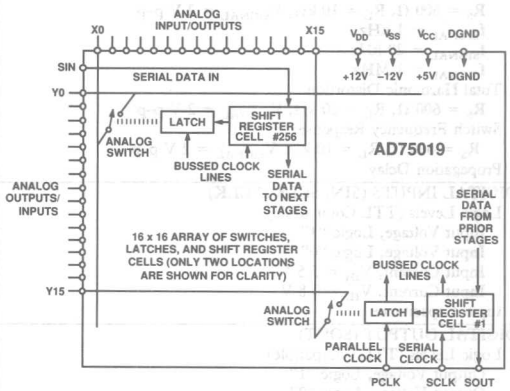
The truth table describes the relationship among the digital inputs (D_0 – D_2) and the analog inputs (S_1 – S_8); and which signal input is selected at the outputs (OUT_1 and OUT_2). The number of crosspoint modules that can be connected in parallel is limited by the drive capabilities of the input signal sources. High input impedance (3MΩ) and low input capacitance (2pF) of the AD9300 help minimize this limitation.

8 × 2 Crosspoint Truth Table

D_2 or D_5	D_1 or D_4	D_0 or D_3	OUT_1 or OUT_2
0	0	0	S_1
0	0	1	S_2
0	1	0	S_3
0	1	1	S_4
1	0	0	S_5
1	0	1	S_6
1	1	0	S_7
1	1	1	S_8

Adding to the number of inputs applied to each crosspoint module is simply a matter of adding AD9300 multiplexers in parallel to the module. Eight devices connected in parallel result in a 32 × 1 crosspoint which can be used with input signals having 30MHz bandwidth and 1V peak-to-peak amplitude. Even more AD9300 units can be added if input signal amplitude and/or bandwidth are reduced; if they are not, distortion of the output signals can result.

When an AD9300 is enabled, its low output impedance causes the "off" isolation of disabled parallel devices to be greater than the crosstalk rejection of a single unit.



16 × 16 Crosspoint Switch Array

AD75019

FEATURES

256 Switches in a 16 × 16 Array
Wide Signal Range: to Supply Rails of 24 V or ±12 V
Low On-Resistance: 200 Ω typ
TTL/CMOS/Microprocessor-Compatible Control Lines
Serial Input Simplifies Interface
Serial Output Allows Cascading for More Channels
Low Power Consumption: 2 mW Quiescent
Compact 44-Pin Package

FUNCTIONAL BLOCK DIAGRAM

PRODUCT DESCRIPTION

The AD75019 contains 256 analog switches in a 16 × 16 array. Any of the X or Y pins may serve as an input or output. Any or all of the X terminals may be programmed to connect to any or all of the Y terminals. The switches can accommodate signals with amplitudes up to the supply rails and have a typical on-resistance of 150 Ω.

Data is loaded serially via the SIN input and clocked into an on-board 256-bit shift register via SCLK. When all the switch settings have been programmed, data is transferred into a set of 256 latches via PCLK. The serial shift register is dynamic, so there is a minimum clock rate of 20 kHz. The maximum clock rate of 5 MHz allows loading times as short as 52 µs. The switch control latches are static and will hold their data as long as power is applied.

To extend the number of switches in the array, you may cascade multiple AD75019s. The SOUT output is the end of the shift register, and may be connected to the SIN input of the next AD75019.

The AD75019 is fabricated in Analog Devices' BiMOS II process. This epitaxial BiCMOS process features CMOS devices for low-distortion switches and bipolar devices for ESD protection.

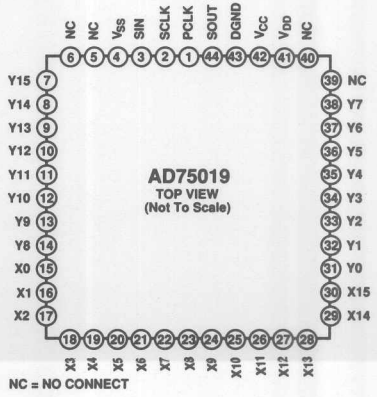
NOTES

[1]All minimum and maximum specifications are guaranteed, and specifications shown in **boldface** are tested on all production units at final electrical test. Results from those tests are used to calculate outgoing quality levels.



[2]Switch resistance matching is measured with zero volts at each analog input and refers to the difference between the maximum and minimum values.

Specifications subject to change without notice.

PIN DESCRIPTION

Pin	Name	Description
1	PCLK	Parallel Clock Input
2	SCLK	Serial Clock Input
3	SIN	Serial Data Input

TIMING DIAGRAM

OPERATION TRUTH TABLE

Control Lines PCLK	SCLK	SIN	SOUT	Operation/ Comment
1	0	X	X	No operation.
1	1	$Data_i$	$Data_{i-256}$	The data on the SIN line is loaded into the serial register; data clocked into the serial register 256 clocks ago appears at the SOUT output.
0	X	X	X	Data in the serial shift register transfers into the parallel latches which control the switch array.

APPLICATIONS INFORMATION

Loading Data

Data to control the switches is clocked serially into a 256-bit shift register and then transferred in parallel to 256 bits of memory. The rising edge of SCLK, the serial clock input, loads data into the shift register. The first bit loaded via SIN, the serial data input, controls the switch at the intersection of row Y15 and column X15. The next bits control the remaining columns (down to X0) of row Y15, and are followed by the bits for row Y14, and so on down to the data for the switch at the intersection of row Y0 and column X0. The shift register is dynamic, so there is a minimum clock rate, specified as 20 kHz.

After the shift register is filled with the new 256 bits of control data, PCLK is activated (pulsed low) to transfer the data to the parallel latches. Since the shift register is dynamic, there is a maximum time delay specified before the data is lost: PCLK must be activated and brought back high within 5 ms after filling the shift register. The switch control latches are static and will hold their data as long as power is applied.

To extend the number of switches in the array, you may cascade multiple AD75019s. The SOUT output is the end of the shift register, and may be directly connected to the SIN input of the next AD75019.

Power Supply Sequencing and Bypassing

All junction-isolated parts operating on multiple power supplies require proper attention to supply sequencing. Because BiMOS II is a junction-isolated process, parasitic diodes exist between V_{DD} and V_{CC}, and between V_{SS} and DGND. As a result, V_{DD} must always be greater than (V_{CC} − 0.5 V), and V_{SS} must always be less than (DGND + 0.5 V).

If you can't ensure that system power supplies will sequence to meet these conditions, external Schottky (e.g., 1N5818) or silicon (e.g., 1N4001) diodes may be used. To protect the positive side, the anode would connect to V_{CC} (Pin 42) and the cathode to V_{DD} (Pin 41). For the negative side, connect the anode to V_{SS} (Pin 4) and the cathode to DGND (Pin 43).

Each of the three power supply pins [V_{DD} (Pin 41), V_{CC} (Pin 42) and V_{SS} (Pin 4)] should be bypassed to DGND (Pin 43) through a 0.1 µF ceramic capacitor located close to the package pins.

Transistor Count

AD75019 contains 5,472 transistors. This number may be used for calculating projected reliability.

ABSOLUTE MAXIMUM RATINGS*

	Min	Max	Units	Conditions
V_{DD} to DGND	−0.5	+25.2	V	
V_{SS} to DGND	−25.2	+0.5	V	
V_{CC} to DGND	−0.5	+5.5	V	
V_{DD} to V_{SS}	−0.5	+25.2	V	
V_{CC} to V_{SS}	−0.5	+25.2	V	
Digital Inputs to DGND	−0.3	V_{CC} +0.5	V	
Power Dissipation		1.0	W	$T_A \leq 75°C$
Operating Temperature Range	0	+70	°C	
Storage Temperature	−65	+150	°C	
Lead Temperature		+300	°C	Soldering, 10 sec

*Stresses above those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. These are stress ratings only and functional operation of the device at these or any other conditions above those indicated in the operational sections of this specification is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

CAUTION

ESD (electrostatic discharge) sensitive device. The digital control inputs are Zener protected; however, permanent damage may occur on unconnected devices subject to high energy electrostatic fields. Unused devices must be stored in conductive foam or shunts. The protective foam should be discharged to the destination socket before devices are removed.

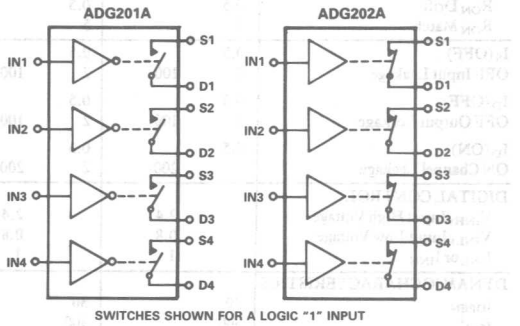
*P = Plastic Leaded Chip Carrier (PLCC) Package.



LC²MOS Quad SPST Switches

ADG201A/ADG202A

FEATURES

- 44V Supply Maximum Rating
- ±15V Analog Signal Range
- Low R_{ON} (60Ω)
- Low Leakage (0.5nA)
- Break Before Make Switching
- Extended Plastic Temperature Range (−40°C to +85°C)
- Low Power Dissipation (33mW)
- Available in 16-Lead DIP/ SOIC and 20-Lead PLCC/LCCC Packages
- Superior Second Source:
  - ADG201A Replaces DG201A, HI-201
  - ADG202A Replaces DG202

FUNCTIONAL BLOCK DIAGRAMS

5

GENERAL DESCRIPTION

The ADG201A and ADG202A are monolithic CMOS devices comprising four independently selectable switches. They are designed on an enhanced LC²MOS process which gives an increased signal handling capability of ±15V. These switches also feature high switching speeds and low R_{ON}.

The ADG201A and ADG202A consist of four SPST switches. They differ only in that the digital control logic is inverted. All devices exhibit break before make switching action. Inherent in the design is low charge injection for minimum transients when switching the digital inputs.

PRODUCT HIGHLIGHTS

1. Extended Signal Range:
   These switches are fabricated on an enhanced LC²MOS process, resulting in high breakdown and an increased analog signal range of ±15V.
2. Single Supply Operation:
   For applications where the analog signal is unipolar (0V to 15V), the switches can be operated from a single +15V supply.
3. Low Leakage:
   Leakage currents in the range of 500pA make these switches suitable for high precision circuits. The added feature of Break before Make allows for multiple outputs to be tied together for multiplexer applications while keeping leakage errors to a minimum.

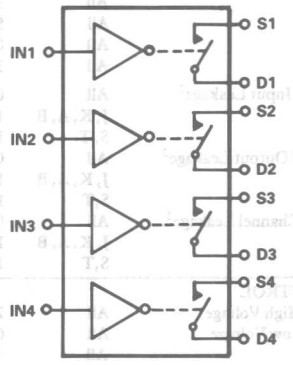
TERMINOLOGY

R_{ON}	Ohmic resistance between terminals OUT and S
R_{ON} Match	Difference between the R_{ON} of any two channels
I_S (OFF)	Source terminal leakage current when the switch is off
I_D (OFF)	Drain terminal leakage current when the switch is off
I_D (ON)	Leakage current that flows from the closed switch into the body
V_D (V_S)	Analog voltage on terminal D, S
C_S (OFF)	Switch input capacitance "OFF" condition
C_D (OFF)	Switch output capacitance "OFF" condition
C_{IN}	Digital input capacitance
C_D, C_S (ON)	Input or output capacitance when the switch is on
t_{ON}	Delay time between the 50% and 90% points of the digital input and switch "ON" condition
t_{OFF}	Delay time between the 50% and 90% points of the digital input and switch "OFF" condition
t_{OPEN}	"OFF" time measured between 50% points of both switches, which are connected as a multiplexer, when switching from one address state to another
V_{INL}	Maximum Input Voltage for a Logic Low
V_{INH}	Minimum Input Voltage for a Logic High
I_{INL} (I_{INH})	Input current of the digital input
V_{DD}	Most positive voltage supply
V_{SS}	Most negative voltage supply
I_{DD}	Positive supply current
I_{SS}	Negative supply current

ANALOG DEVICES



LC²MOS High Speed, Quad SPST Switch

ADG201HS

FEATURES

- 50ns max Switching Time Over Full Temperature Range
- Low R_{ON} (30Ω typ)
- Single Supply Specifications for +10.8V to +16.5V Operation
- Extended Plastic Temperature Range (−40°C to +85°C)
- Break-Before-Make Switching
- Low Leakage (100pA typ)
- 44V Supply max Rating
- Available in 16-Lead DIP/SOIC and 20-Lead LCCC/PLCC Packages
- ADG201HS (K, B, T) Replaces HI-201HS
- ADG201HS (J, A, S) Replaces DG271

FUNCTIONAL BLOCK DIAGRAM

5

GENERAL DESCRIPTION

The ADG201HS is a monolithic CMOS device comprising four independently selectable SPST switches. It is designed on an enhanced LC²MOS process which gives very fast switching speeds and low R_{ON}.

The switches also feature break-before-make switching action for use in multiplexer applications and low charge injection for minimum transients on the output when switching the digital inputs.

NOTES
[1]To order MIL-STD-883, Class B processed parts, add /883B to T grade part numbers. See the Analog Devices Military Products Databook (1990) for military data sheet.
[2]E = Leadless Ceramic Chip Carrier; N = Narrow Plastic DIP; P = Plastic Leaded Chip Carrier; Q = Cerdip; R = 0.15″ Small Outline IC (SOIC). For outline information see Package Information section.
[3]Standard Military Drawing (SMD) approved by DESC. SMD numbers are
5962-86716012X (ADG201HSTE/883B)
5962-8671601EX (ADG201HSTQ/883B)

PRODUCT HIGHLIGHTS

1. 50ns max t_{ON} and t_{OFF}
   The ADG201HS top grades (K, B, T) have guaranteed 50ns max turn-on and turn-off times over the full operating temperature range. The lower grades (J, A, S) have guaranteed 75ns switching times over the full operating temperature range.
2. Single Supply Specifications
   The ADG201HS is fully specified for applications which require a single positive power supply in the +10.8V to +16.5V range.
3. Low Leakage
   Leakage currents in the range of 100pA make these switches suitable for high precision circuits. The added feature of break-before-make allows for multiple outputs to be tied together for multiplexer applications while keeping leakage errors to a minimum.

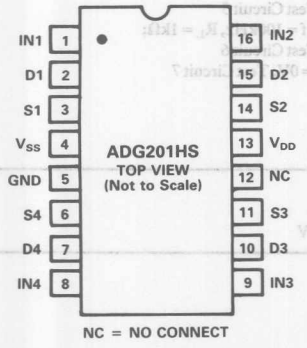
ABSOLUTE MAXIMUM RATINGS*
(T_A = 25°C unless otherwise noted)

V_{DD} to V_{SS}	44V
V_{DD} to GND	−0.3V, 25V
V_{SS} to GND[1]	+0.3V, −25V
Analog Inputs[2]	
Voltage at S, D	V_{SS} −2V to V_{DD} +2V or 20mA, Whichever Occurs First
Continuous Current, S or D	20mA
Pulsed Current S or D	
1ms Duration, 10% Duty Cycle	70mA
Digital Inputs[2]	
Voltage at IN	V_{SS} −4V to V_{DD} +4V or 20mA, Whichever Occurs First
Power Dissipation (Any Package)	
Up to +75°C	470mW
Derates above +75°C by	6mW/°C
Operating Temperature	
Commerical (J, K Version)	−40°C to +85°C
Industrial (A, B Version)	−40°C to +85°C
Extended (S, T Version)	−55°C to +125°C
Storage Temperature Range	−65°C to +150°C
Lead Temperature (Soldering 10sec)	+300°C

NOTES
[1]If V_{SS} is open circuited with V_{DD} and GND applied, the V_{SS} pin will be pulled positive, exceeding the Absolute Maximum Ratings. If this possibility exists, a Schottky diode from V_{SS} to GND (cathode end to GND) ensures that the Absolute Maximum Ratings will be observed.
[2]Overvoltage at IN, S or D, will be clamped by diodes. Current should be limited to the maximum rating above.



*COMMENT: Stresses above those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. This is a stress rating only and functional operation of the device at these or any other conditions above those indicated in the operational sections of this specification is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

CAUTION:
ESD (electrostatic discharge) sensitive device. The digital control inputs are diode protected; however, permanent damage may occur on unconnected devices subject to high energy electrostatic fields. Unused devices must be stored in conductive foam or shunts. The protective foam should be discharged to the destination socket before devices are inserted.

SINGLE SUPPLY DISK DRIVE APPLICATION

The excellent performance of the ADG201HS with single supply operation makes it suitable in applications such as disk drives where only positive power supply voltages are normally available. The accompanying circuit shows a typical application for the ADG201HS in the read/write head switching section of a disk drive. The circuit allows data (0s and 1s) to be written to and read from a disk. The principal advantage offered by the ADG201HS is that it retains very fast switching speed with single supply operation (see Single Supply Specifications). This allows disk drives to run at higher data rates.

ADG211A/ADG212A

FEATURES
44V Supply Maximum Rating
±15V Analog Signal Range
Low R_{ON} (115Ω max)
Low Leakage (0.5nA typ)
Break Before Make Switching
Single Supply Operation Possible
Extended Plastic Temperature Range (−40°C to +85°C)
TTL/CMOS Compatible
Available in 16-Lead DIP/SOIC and 20-Lead PLCC Packages
Superior Second Source:
ADG211A Replaces DG211
ADG212A Replaces DG212

SWITCHES SHOWN FOR A LOGIC "1" INPUT

5

GENERAL DESCRIPTION

The ADG211A and ADG212A are monolithic CMOS devices comprising four independently selectable switches. They are designed on an enhanced LC^2MOS process which gives an increased signal handling capability of ±15V. These switches also feature high switching speeds and low R_{ON}.

The ADG211A and ADG212A consist of four SPST switches. They differ only in that the digital control logic is inverted. In multiplexer applications, all switches exhibit break-before-make switching action when driven simultaneously. Inherent in the design is low charge injection for minimum transients when switching the digital inputs.

PRODUCT HIGHLIGHTS

1. Extended Signal Range:
   These switches are fabricated on an enhanced LC^2MOS process, resulting in high breakdown and an increased analog signal range of ±15V.
2. Single Supply Operation:
   For applications where the analog signal is unipolar (0V to 15V), the switches can be operated from a single +15V supply.
3. Low Leakage:
   Leakage currents in the range of 500pA make these switches suitable for high precision circuits. The added feature of Break before Make allows for multiple outputs to be tied together for multiplexer applications while keeping leakage errors to a minimum.

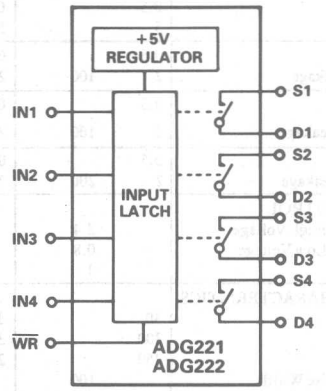
TERMINOLOGY

R_{ON}	Ohmic resistance between terminals OUT and S
R_{ON} Match	Difference between the R_{ON} of any two channels
I_S (OFF)	Source terminal leakage current when the switch is off
I_D (OFF)	Drain terminal leakage current when the switch is off
I_D (ON)	Leakage current that flows from the closed switch into the body
V_D (V_S)	Analog voltage on terminal D, S
C_S (OFF)	Switch input capacitance "OFF" condition
C_D (OFF)	Switch output capacitance "OFF" condition
C_{IN}	Digital input capacitance
C_D, C_S (ON)	Input or output capacitance when the switch is on
t_{ON}	Delay time between the 50% and 90% points of the digital input and switch "ON" condition
t_{OFF}	Delay time between the 50% and 90% points of the digital input and switch "OFF" condition
t_{OPEN}	"OFF" time measured between 50% points of both switches, which are connected as a multiplexer, when switching from one address state to another
V_{INL}	Maximum Input Voltage for a Logic Low
V_{INH}	Minimum Input Voltage for a Logic High
I_{INL} (I_{INH})	Input current of the digital input
V_{DD}	Most positive voltage supply
V_{SS}	Most negative voltage supply
V_L	Logic supply voltage
I_{DD}	Positive supply current
I_{SS}	Negative supply current



LC²MOS Quad SPST Switches

ADG221/ADG222

FEATURES

- 44V Supply Maximum Rating
- ±15V Analog Signal Range
- Low R_{ON} (60Ω)
- Low Leakage (0.5nA)
- Break Before Make Switching
- Extended Plastic Temperature Range (−40°C to +85°C)
- Low Power Dissipation (25.5mW)
- µP, TTL, CMOS Compatible
- Available in 16-Lead DIP/SOIC and 20-Lead PLCC/LCCC Packages
- Surface Mount Packages
- Superior DG221 Replacement

FUNCTIONAL BLOCK DIAGRAM

5

GENERAL DESCRIPTION

The ADG221 and ADG222 are monolithic CMOS devices comprising four independently selectable switches. On-chip latches facilitate microprocessor interfacing. They are designed on an enhanced LC²MOS process which gives an increased signal handling capability of ±15V. These switches also feature high switching speeds and low R_{ON}.

The ADG221 and ADG222 consist of four SPST switches. They differ only in that the digital control logic is inverted. All devices exhibit break before make switching action. Inherent in the design is low charge injection for minimum transients when switching the digital inputs.

PRODUCT HIGHLIGHTS

1. Easily Interfaced:
   Digital inputs are latched with a $\overline{WR}$ signal for microprocessor interfacing. A 5V regulated supply is internally generated permitting wider tolerances on the supplies without affecting the TTL digital input switching levels.
2. Single Supply Operation:
   For applications where the analog signal is unipolar (0V to 15V), the switches can be operated from a single +15V supply.
3. Low Leakage:
   Leakage currents in the range of 500pA make these switches suitable for high precision circuits. The added feature of Break before Make allows for multiple outputs to be tied together for multiplexer applications while keeping leakage errors to a minimum.

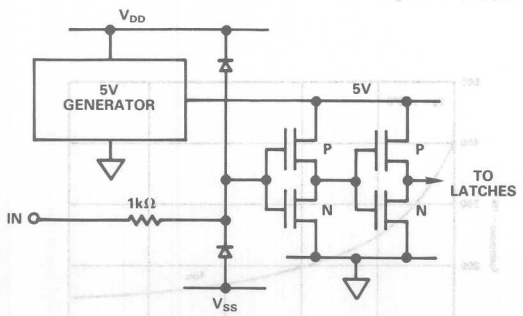

Figure 1. Typical Digital Input Cell

TIMING AND CONTROL SEQUENCE

Figure 2 shows the timing sequence for latching the switch digital inputs (IN1 – IN4). The latches are level sensitive and, therefore, while $\overline{WR}$ is held low the latches are transparent and the switches respond to the digital inputs. The digital inputs are latched on the rising edge of $\overline{WR}$.

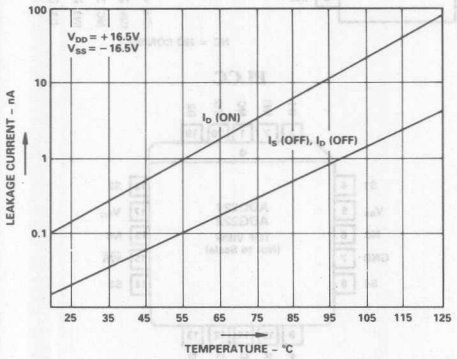
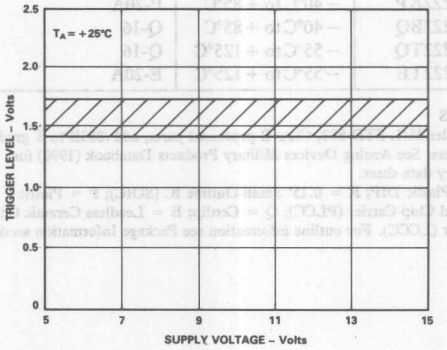
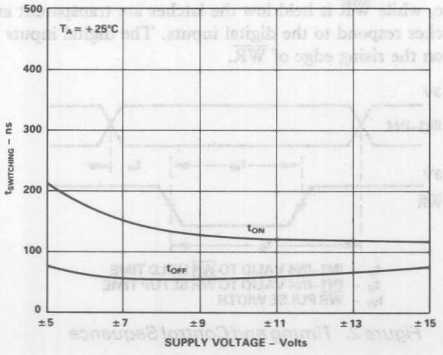
ADG221/ADG222—Typical Performance Characteristics



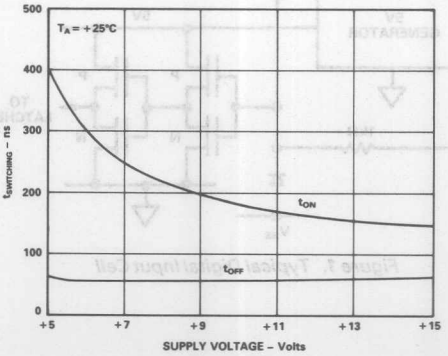
The switches are guaranteed functional with reduced single or dual supplies down to 4.5V.



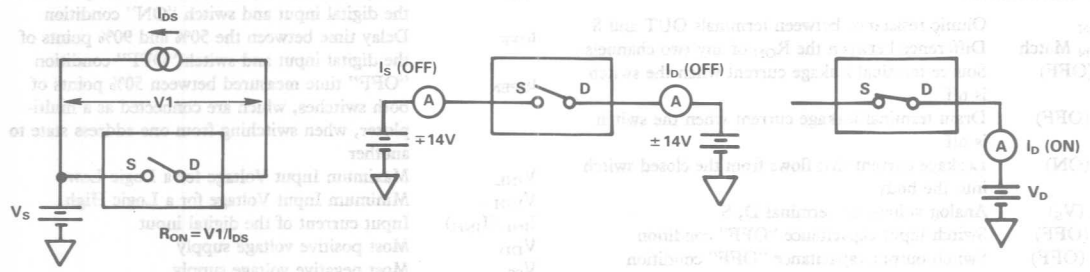
R_{ON} as a Function of V_D (V_S): Dual Supply Voltage



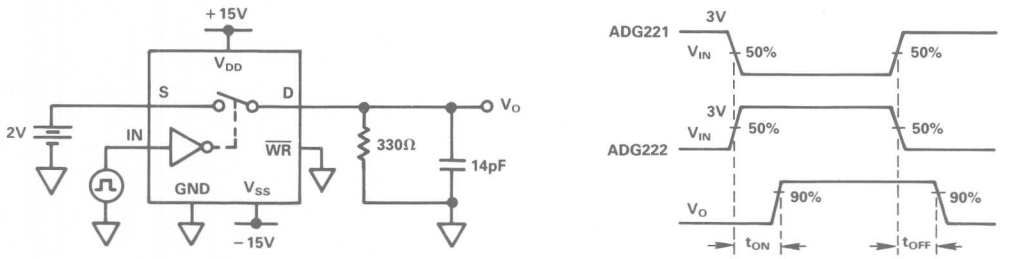
R_{ON} as a Function of V_D (V_S): Single Supply Voltage



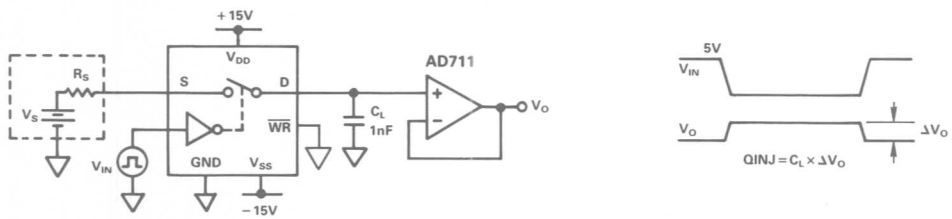
Leakage Current as a Function of Temperature (Note: Leakage Currents Reduce as the Supply Voltages Reduce)



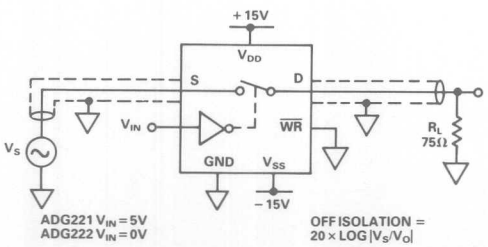
Trigger Level vs. Power Supply Voltage: Dual or Single Supply Voltage



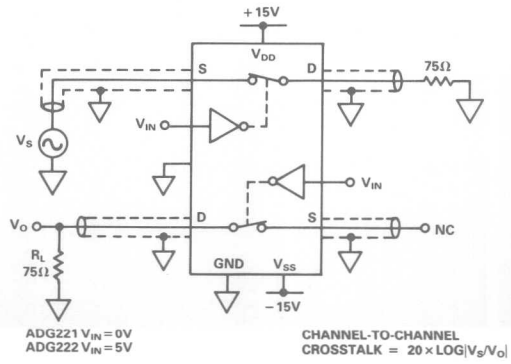
Switching Times vs. Supply Voltage (Dual Supply)



Switching Times vs. Supply Voltage (Single Supply)



Test Circuit 1 *Test Circuit 2* *Test Circuit 3*



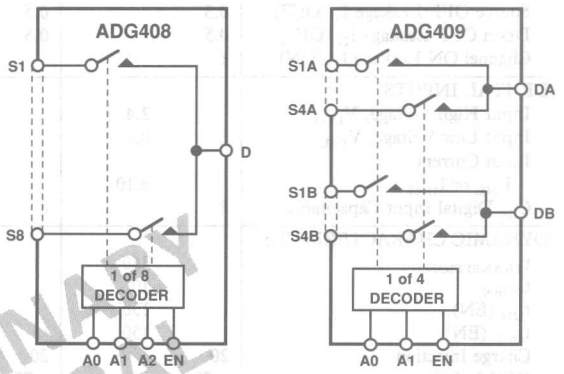
Test Circuit 4

Test Circuit 5. Charge Injection

Test Circuit 6. Off Isolation

Test Circuit 7. Channel-to-Channel Crosstalk

R_{ON}	Ohmic resistance between terminals OUT and S
R_{ON} Match	Difference between the R_{ON} of any two channels
I_S (OFF)	Source terminal leakage current when the switch is off
I_D (OFF)	Drain terminal leakage current when the switch is off
I_D (ON)	Leakage current that flows from the closed switch into the body
V_D (V_S)	Analog voltage on terminal D, S
C_S (OFF)	Switch input capacitance "OFF" condition
C_D (OFF)	Switch output capacitance "OFF" condition
C_{IN}	Digital input capacitance
C_D, C_S (ON)	Input or output capacitance when the switch is on
t_{OFF}	Delay time between the 50% and 90% points of the digital input and switch "OFF" condition
t_{OPEN}	"OFF" time measured between 50% points of both switches, which are connected as a multiplexer, when switching from one address state to another
V_{INL}	Maximum Input Voltage for a Logic Low
V_{INH}	Minimum Input Voltage for a Logic High
I_{INL} (I_{INH})	Input current of the digital input
V_{DD}	Most positive voltage supply
V_{SS}	Most negative voltage supply
I_{DD}	Positive supply current
I_{SS}	Negative supply current



LC²MOS 4/8 Channel High Performance Analog Multiplexers

ADG408/ADG409

FEATURES
- 44 V Supply Maximum Ratings
- V_{SS} to V_{DD} Analog Signal Range
- Low On Resistance (<100 Ω)
- Low Power Dissipation (<2.2 mW)
- Fast Switching
- Latch Up Proof
- Plug-In Replacement for DG408/DG409

APPLICATIONS
- Audio and Video Routing
- Automatic Test Equipment
- Data Acquisition Systems
- Battery Powered Systems
- Sample Hold Systems
- Communication Systems

FUNCTIONAL BLOCK DIAGRAMS

PRELIMINARY TECHNICAL DATA

5

GENERAL DESCRIPTION

The ADG408 and ADG409 are monolithic CMOS analog multiplexers comprising 8 single channels and 4 differential channels, respectively. The ADG408 switches one of 8 inputs to a common output as determined by the 3 bit binary address lines A0, A1, A2. The ADG409 switches one of 4 differential inputs to a common differential output as determined by the 2 bit binary address lines A0 and A1. An EN input on both devices is used to enable or disable the device. When disabled, all channels are switched OFF.

The ADG408/ADG409 are designed on an enhanced LC²MOS, trench isolated process which provides low power dissipation yet gives high switching speed and low on resistance. Each channel conducts equally well in both directions when ON and has an input signal range which extends to the supplies. In the OFF condition signal levels up to the supplies are blocked. All channels exhibit break-before-make switching action preventing momentary shorting when switching channels. Trench isolation gives all the benefits of dielectric isolation and ensures no latch up even under extreme overvoltage conditions. Inherent in the design is low charge injection for minimum transients when switching the digital inputs.

The ADG408/ADG409 are improved replacements for the DG408/DG409 analog multiplexers.

PRELIMINARY TECHNICAL DATA

GENERAL DESCRIPTION

The ADG411 and ADG412 are monolithic CMOS devices comprising four independently selectable switches. They are designed on an enhanced LC²MOS, trench isolated process which provides low power dissipation yet gives high switching speed and low on resistance. Trench isolation gives all the benefits of dielectric isolation and ensures no latch-up even under extreme over-voltage conditions. The on resistance profile is very flat over the full analog input range ensuring good linearity and low distortion when switching audio signals. High switching speed also makes the parts suitable for video signal switching. CMOS construction ensures ultralow power dissipation making the parts ideally suited for portable and battery powered instruments.

Both the ADG411 and the ADG412 contain four independent SPST switches. They differ only in that the digital control logic is inverted. Each switch conducts equally well in both directions when ON and has an input signal range which extends to the supplies. In the OFF condition signal levels up to the supplies are blocked. All switches exhibit break before make switching action for use in multiplexer applications. Inherent in the design is low charge injection for minimum transients when switching the digital inputs.

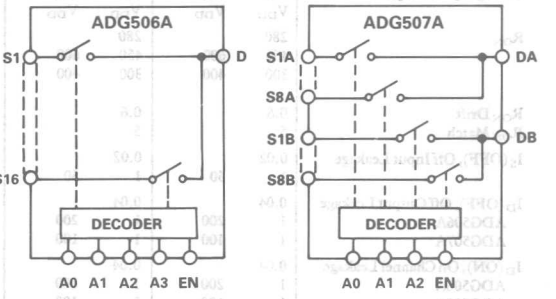
ANALOG DEVICES



CMOS 8/16 Channel Analog Multiplexers

ADG506A/ADG507A

FEATURES

- 44V Supply Maximum Rating
- V_{SS} to V_{DD} Analog Signal Range
- Single/Dual Supply Specifications
- Wide Supply Ranges (10.8V to 16.5V)
- Extended Plastic Temperature Range (−40°C to +85°C)
- Low Power Dissipation (28mW max)
- Low Leakage (20pA typ)
- Available in 28-Lead DIP, SOIC, PLCC and LCCC Packages
- Superior Alternative to:
  - DG506A, HI-506
  - DG507A, HI-507

FUNCTIONAL BLOCK DIAGRAMS

5

GENERAL DESCRIPTION

The ADG506A and ADG507A are CMOS monolithic analog multiplexers with 16 channels and dual 8 channels respectively. The ADG506A switches one of 16 inputs to a common output depending on the state of four binary addresses and an enable input. The ADG507A switches one of 8 differential inputs to a common differential output depending on the state of three binary addresses and an enable input. Both devices have TTL and 5V CMOS logic compatible digital inputs.

The ADG506A and ADG507A are designed on an enhanced LC^2MOS process which gives an increased signal capability of V_{SS} to V_{DD} and enables operation over a wide range of supply voltages. The devices can comfortably operate anywhere in the 10.8V to 16.5V single or dual supply range. These multiplexers also feature high switching speeds and low R_{ON}.

PRODUCT HIGHLIGHTS

1. Single/Dual Supply Specifications with a Wide Tolerance:
   The devices are specified in the 10.8V to 16.5V range for both single and dual supplies.
2. Extended Signal Range:
   The enhanced LC^2MOS processing results in a high breakdown and an increased analog signal range of V_{SS} to V_{DD}.
3. Break-Before-Make Switching:
   Switches are guaranteed break-before-make so that input signals are protected against momentary shorting.
4. Low Leakage:
   Leakage currents in the range of 20pA make these multiplexers suitable for high precision circuits.

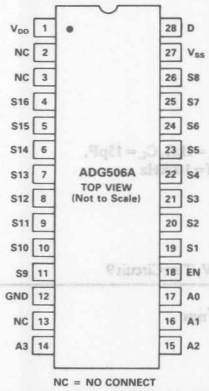
Commercial (K Version)	−40°C to +85°C
Industrial (B Version)	−40°C to +85°C
Extended (T Version)	−55°C to +125°C
Storage Temperature Range	−65°C to +150°C
Lead Temperature (Soldering, 10secs)	+300°C

NOTE

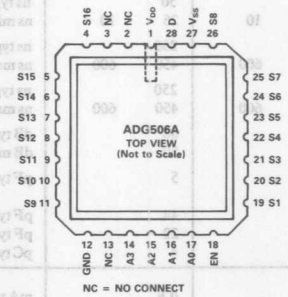
[1]Overvoltage at A, EN, S or D will be clamped by diodes. Current should be limited to the Maximum Rating above.

*COMMENT: Stresses above those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. This is a stress rating only and functional operation of the device at these or any other conditions above those indicated in the operational sections of this specification is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

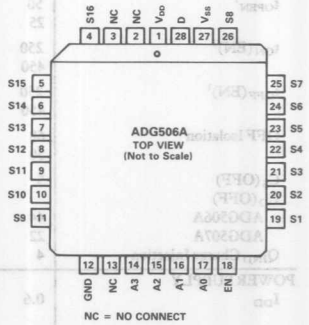


CAUTION

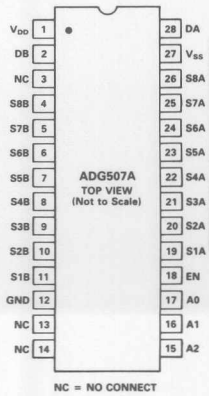
ESD (Electro-Static-Discharge) sensitive device. The digital control inputs are diode protected; however, permanent damage may occur on unconnected devices subject to high energy electrostatic fields. Unused devices must be stored in conductive foam or shunts. The protective foam should be discharged to the destination socket before devices are removed.

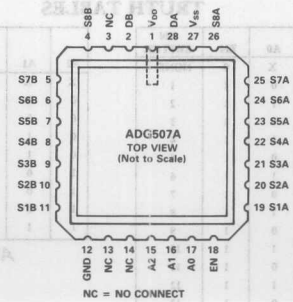


PIN CONFIGURATIONS

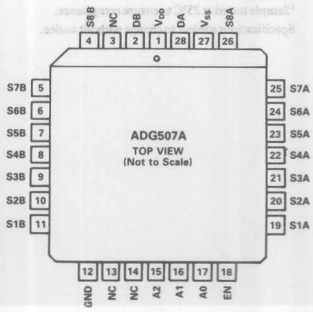


DIP, SOIC

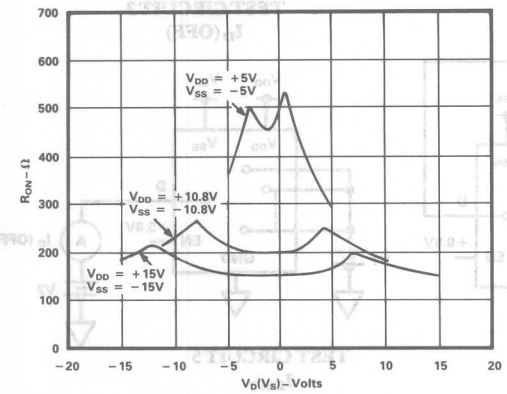


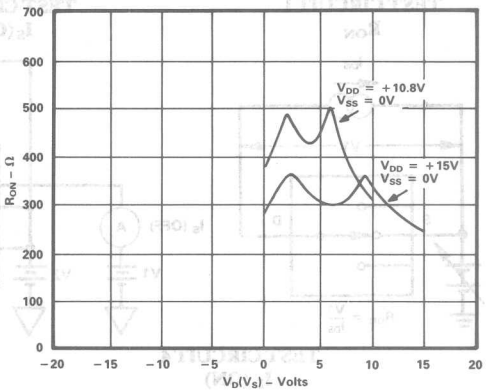


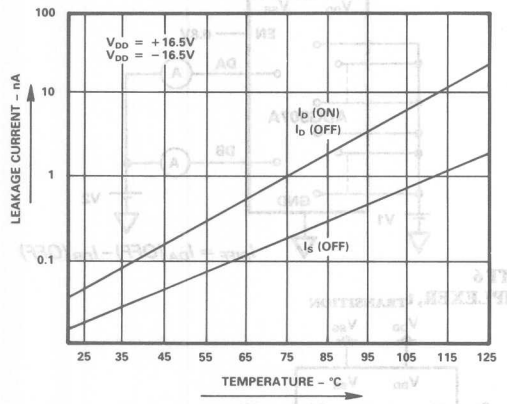
LCCC



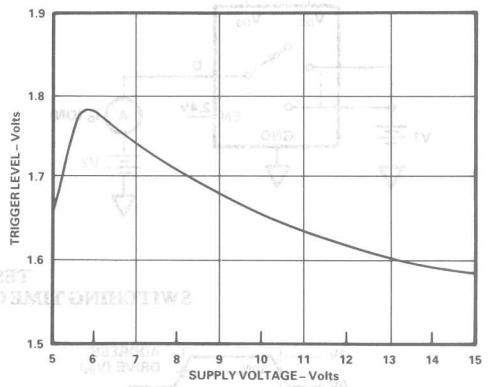
PLCC



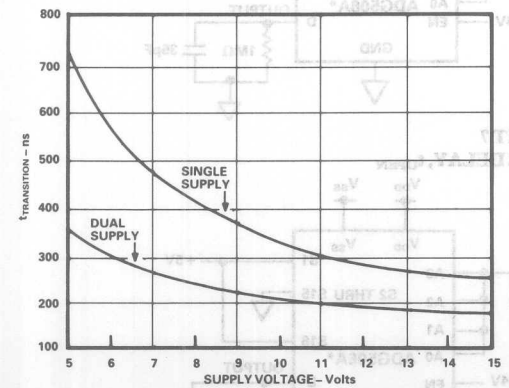




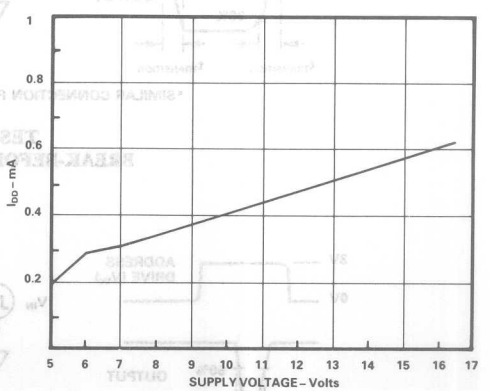
The multiplexers are guaranteed functional with reduced single or dual supplies down to 4.5V.



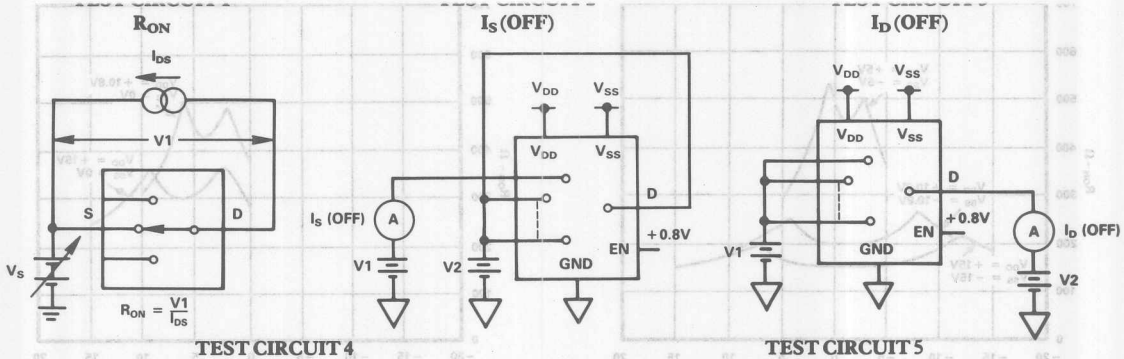
R_{ON} as a Function of $V_D(V_S)$: Dual Supply Voltage, T_A = +25°C



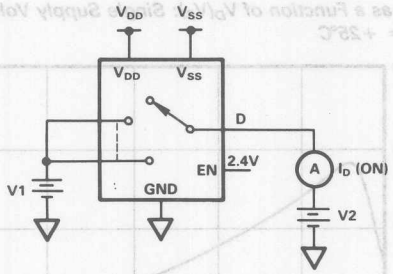
R_{ON} as a Function of $V_D(V_S)$: Single Supply Voltage, T_A = +25°C



Leakage Current as a Function of Temperature (Note: Leakage Currents Reduce as the Supply Voltages Reduce)



Trigger Levels vs. Power Supply Voltage, Dual or Single Supply, T_A = +25°C



$t_{TRANSITION}$ vs. Supply Voltage: Dual and Single Supplies, T_A = +25°C (Note: For V_{DD} and $|V_{SS}| < 10V$; V1 = V_{DD}/V_{SS}, V2 = V_{SS}/V_{DD}. See Test Circuit 6)

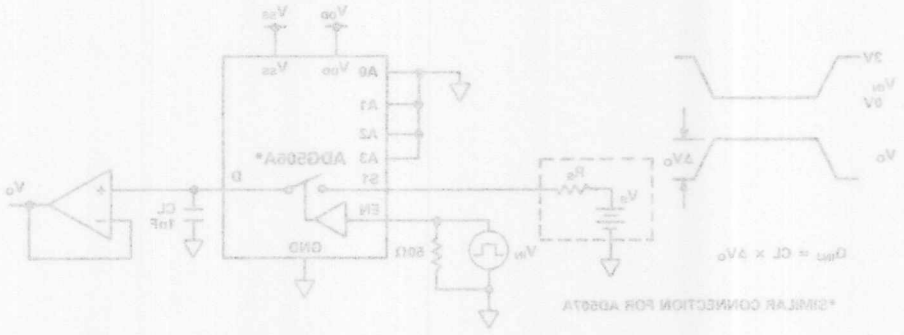
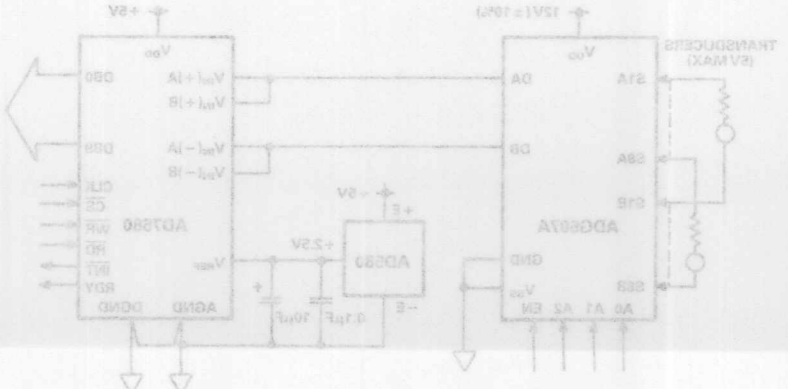
SINGLE SUPPLY AUTOMATIVE APPLICATION

The excellent performance of the multiplexers under single supply conditions makes the ADG506A/ADG507A suitable in applications, such as automotive and disc drives, where only positive power supply voltages are normally available. The following application circuit shows the ADG507A connected as an 8-channel differential multiplexer in an automotive, data acquisition application circuit.



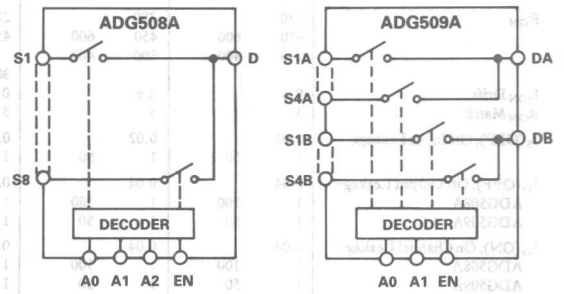
The AD7580 is a 10-bit successive approximation ADC which has an on-chip sample-hold amplifier and provides a conversion result in 20μs. The ADC has a differential analog inputs and is configured in the application circuit for a span of 2.5V over a common-mode range 0 to +5V. Wider common-mode ranges can be accomodated. See the AD7579/AD7580 data sheet for more details. The complete system operates from +12V (±10%) and +5V supplies. The analog input signals to the ADG507A contain information such as temperature, pressure, speed etc.



ADG507A in a Single Supply Automotive Data Acquisition Application.

TERMINOLOGY

R_{ON}	Ohmic resistance between terminals D and S
R_{ON} Match	Difference between the R_{ON} of any two channels
R_{ON} Drift	Change in R_{ON} versus temperature
I_S (OFF)	Source terminal leakage current when the switch is off
I_D (OFF)	Drain terminal leakage current when the switch is off
I_D (ON)	Leakage current that flows from the closed switch into the body
V_S (V_D)	Analog voltage on terminal S or D
C_S (OFF)	Channel input capacitance for "OFF" condition
C_D (OFF)	Channel output capacitance for "OFF" condition
C_{IN}	Digital input capacitance
t_{ON} (EN)	Delay time between the 50% and 90% points of the digital input and switch "ON" condition
t_{OFF} (EN)	Delay time between the 50% and 10% points of the digital input and switch "OFF" condition
$t_{TRANSITION}$	Delay time between the 50% and 90% points of the digital inputs and switch "ON" condition when switching from one address state to another
t_{OPEN}	"OFF" time measured between 50% points of both switches when switching from one address state to another
V_{INL}	Maximum input voltage for Logic "0"
V_{INH}	Minimum input voltage for Logic "1"
I_{INL} (I_{INH})	Input current of the digital input
V_{DD}	Most positive voltage supply
V_{SS}	Most negative voltage supply
I_{DD}	Positive supply current
I_{SS}	Negative supply current



CMOS
4/8 Channel Analog Multiplexers

ADG508A/ADG509A

FEATURES
- 44V Supply Maximum Rating
- V_{SS} to V_{DD} Analog Signal Range
- Single/Dual Supply Specifications
- Wide Supply Ranges (10.8V to 16.5V)
- Extended Plastic Temperature Range (−40°C to +85°C)
- Low Power Dissipation (28mW max)
- Low Leakage (20pA typ)
- Available in 16-Lead DIP/SOIC and 20-Lead PLCC/LCCC Packages
- Superior Alternative to:
  - DG508A, HI-508
  - DG509A, HI-509

FUNCTIONAL BLOCK DIAGRAMS

5

GENERAL DESCRIPTION

The ADG508A and ADG509A are CMOS monolithic analog multiplexers with 8 channels and dual 4 channels respectively. The ADG508A switches one of 8 inputs to a common output depending on the state of three binary addresses and an enable input. The ADG509A switches one of 4 differential inputs to a common differential output depending on the state of two binary addresses and an enable input. Both devices have TTL and 5V CMOS logic compatible digital inputs.

The ADG508A and ADG509A are designed on an enhanced LC^{2}MOS process which gives an increased signal capability of V_{SS} to V_{DD} and enables operation over a wide range of supply voltages. The devices can comfortably operate anywhere in the 10.8V to 16.5V single or dual supply range. These multiplexers also feature high switching speeds and low R_{ON}.

PRODUCT HIGHLIGHTS

1. Single/Dual Supply Specifications with a Wide Tolerance:
   The devices are specified in the 10.8V to 16.5V range for both single and dual supplies.
2. Extended Signal Range:
   The enhanced LC^{2}MOS processing results in a high breakdown and an increased analog signal range of V_{SS} to V_{DD}.
3. Break-Before-Make Switching:
   Switches are guaranteed break-before-make so that input signals are protected against momentary shorting.
4. Low Leakage:
   Leakage currents in the range of 20pA make these multiplexers suitable for high precision circuits.

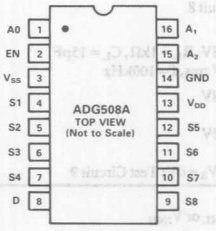
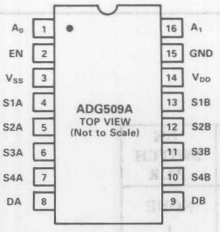
Storage Temperature Range . . . . . −65°C to +150°C

NOTE
[1]Overvoltage at A, EN, S or D will be clamped by diodes. Current should be limited to the Maximum Rating above.

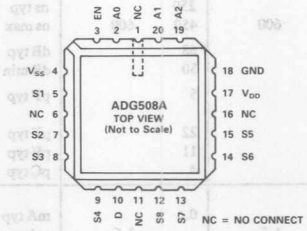
*COMMENT: Stresses above those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. This is a stress rating only and functional operation of the device at these or any other conditions above those indicated in the operational sections of this specification is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.



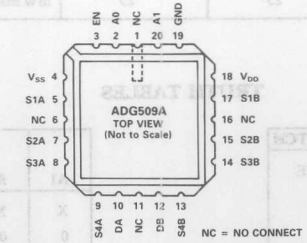
CAUTION



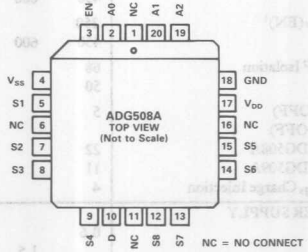
ESD (electrostatic discharge) sensitive device. The digital control inputs are diode protected; however, permanent damage may occur on unconnected devices subject to high energy electrostatic fields. Unused devices must be stored in conductive foam or shunts. The protective foam should be discharged to the destination socket before devices are removed.

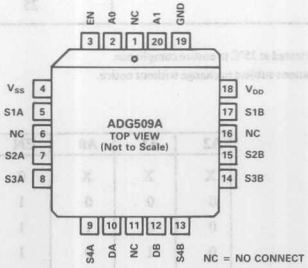


PIN CONFIGURATIONS

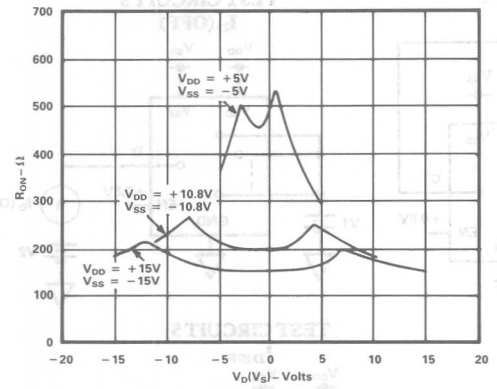


DIP, SOIC

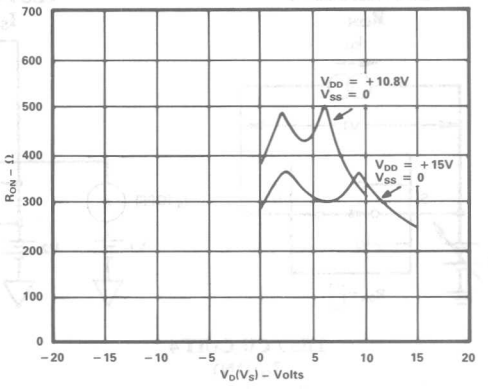


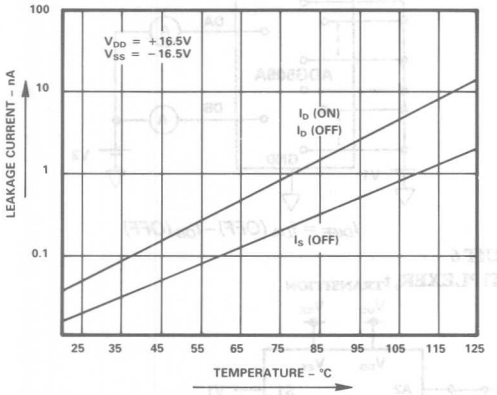


LCCC

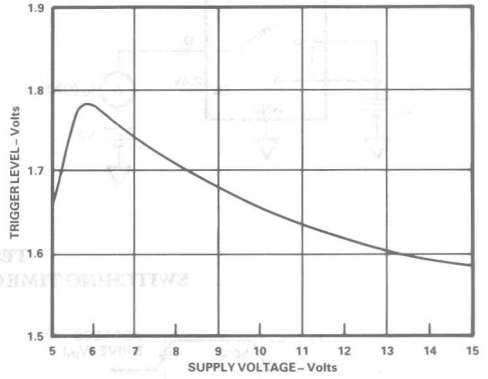


PLCC

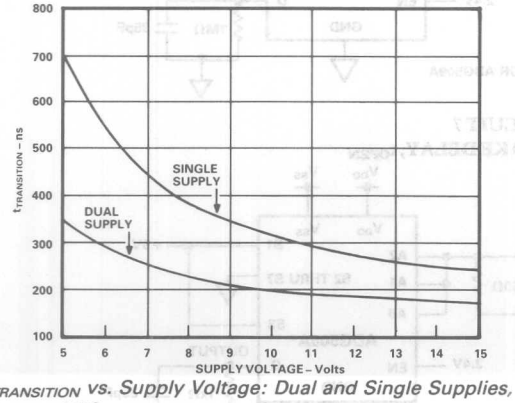




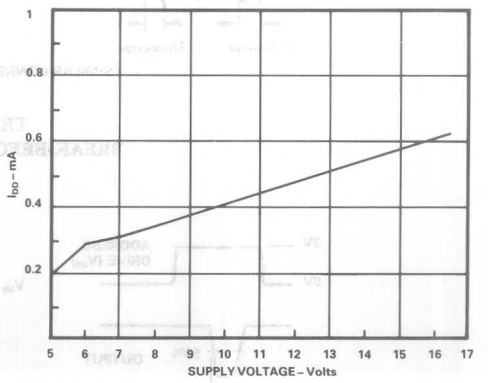
The multiplexers are guaranteed functional with reduced single or dual supplies down to 4.5V.



R_{ON} as a Function of $V_D(V_S)$: Dual Supply Voltage, T_A = +25°C



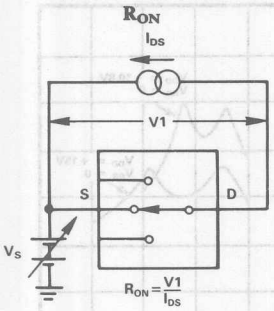
R_{ON} as a Function of $V_D(V_S)$: Single Supply Voltage, T_A = +25°C



Leakage Current as a Function of Temperature (Note: Leakage Currents Reduce as the Supply Voltages Reduce)

Trigger Levels vs. Power Supply Voltage, Dual or Single Supply, T_A = +25°C

$t_{TRANSITION}$ vs. Supply Voltage: Dual and Single Supplies, T_A = +25°C (Note: For V_{DD} and $|V_{SS}| < 10V$; V1 = V_{DD}/V_{SS}, V2 = V_{SS}/V_{DD}. See Test Circuit 6)



I_{DD} vs. Supply Voltage: Dual or Single Supply, T_A = +25°C

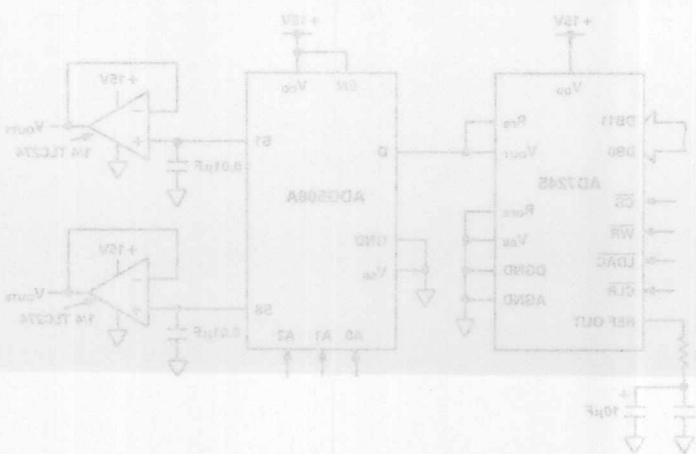
SINGLE SUPPLY OCTAL DAC APPLICATION

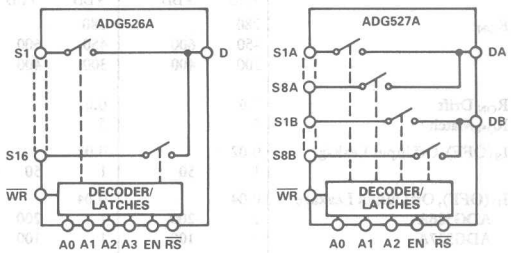


The following circuit shows the ADG508A connected as a demultiplexer to provide eight separate digitally programmable voltages (0 to +10V) from the AD7245. The AD7245 is a complete 12-bit, voltage output DAC with output amplifier and Zener voltage reference on a monolithic CMOS chip. The entire system operates from a single +15V power supply. The ADG508A is ideally suited for the application because it has both low charge injection and I_S (OFF) leakage current.

ADG508A in a Single-Supply Octal DAC Circuit

R_{ON}	Ohmic resistance between terminals D and S
R_{ON} Match	Difference between the R_{ON} of any two channels
R_{ON} Drift	Change in R_{ON} versus temperature
I_S (OFF)	Source terminal leakage current when the switch is off
I_D (OFF)	Drain terminal leakage current when the switch is off
I_D (ON)	Leakage current that flows from the closed switch into the body
V_S (V_D)	Analog voltage on terminal S or D
C_S (OFF)	Channel input capacitance for "OFF" condition
C_D (OFF)	Channel output capacitance for "OFF" condition
C_{IN}	Digital input capacitance
t_{ON} (EN)	Delay time between the 50% and 90% points of the digital input and switch "ON" condition
t_{OFF} (EN)	Delay time between the 50% and 10% points of the digital input and switch "OFF" condition
$t_{TRANSITION}$	Delay time between the 50% and 90% points of the digital inputs and switch "ON" condition when switching from one address state to another
t_{OPEN}	"OFF" time measured between 50% points of both switches when switching from one address state to another
V_{INL}	Maximum input voltage for Logic "0"
V_{INH}	Minimum input voltage for Logic "1"
I_{INL} (I_{INH})	Input current of the digital input
V_{DD}	Most positive voltage supply
V_{SS}	Most negative voltage supply
I_{DD}	Positive supply current
I_{SS}	Negative supply current

ANALOG DEVICES



CMOS Latched 8/16 Channel Analog Multiplexers

ADG526A/ADG527A

FEATURES

- 44V Supply Maximum Rating
- V_{SS} to V_{DD} Analog Signal Range
- Single/Dual Supply Specifications
- Wide Supply Ranges (10.8V to 16.5V)
- Microprocessor Compatible (100ns $\overline{WR}$ Pulse)
- Extended Plastic Temperature Range (−40°C to +85°C)
- Low Leakage (20pA typ)
- Low Power Dissipation (28mW max)
- Available in DIP, SOIC, PLCC and LCCC Packages
- Superior Alternative to:
  - DG526
  - DG527

FUNCTIONAL BLOCK DIAGRAMS

5

GENERAL DESCRIPTION

The ADG526A and ADG527A are CMOS monolithic analog multiplexers with 16 channels and dual 8 channels respectively. On-chip latches facilitate microprocessor interfacing. The ADG526A switches one of 16 inputs to a common output depending on the state of four binary addresses and an enable input. The ADG527A switches one of 8 differential inputs to a common differential output depending on the state of three binary addresses and an enable input. Both devices have TTL and 5V CMOS logic compatible digital inputs.

The ADG526A and ADG527A are designed on an enhanced LC^2MOS process which gives an increased signal capability of V_{SS} to V_{DD} and enables operation over a wide range of supply voltages. The devices can comfortably operate anywhere in the 10.8V to 16.5V single or dual supply range. These multiplexers also feature high switching speeds and low R_{ON}.

PRODUCT HIGHLIGHTS

1. Single/Dual Supply Specifications with a Wide Tolerance:
   The devices are specified in the 10.8V to 16.5V range for both single and dual supplies.
2. Easily Interfaced:
   The ADG526A and ADG527A can be easily interfaced with microprocessors. The $\overline{WR}$ signal latches the state of the Address control lines and the Enable line. The $\overline{RS}$ signal clears both the address and enable data in the latches resulting in no output (all switches off). $\overline{RS}$ can be tied to the microprocessor reset pin.
3. Extended Signal Range:
   The enhanced LC^2MOS processing results in a high breakdown and an increased analog signal range of V_{SS} to V_{DD}.
4. Break-Before-Make Switching:
   Switches are guaranteed break-before-make so that input signals are protected against momentary shorting.
5. Low Leakage:
   Leakage currents in the range of 20pA make these multiplexers suitable for high precision circuits.

TIMING DIAGRAMS

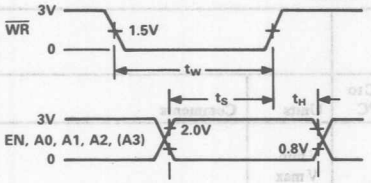

Figure 1.

Figure 1 shows the timing sequence for latching the switch address and enable inputs. The latches are level sensitive; therefore, while $\overline{WR}$ is held low, the latches are transparent and the switches respond to the address and enable inputs. This input data is latched on the rising edge of $\overline{WR}$.

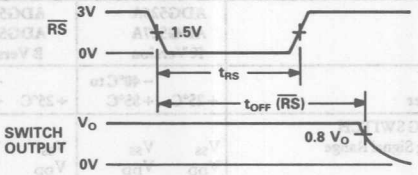

Figure 2.

Figure 2 shows the Reset Pulse Width, t_{RS}, and Reset Turn-off Time, t_{OFF} ($\overline{RS}$).

Note: All digital input signals rise and fall times measured from 10% to 90% of 3V. $t_R = t_F = 20ns$.

Power Dissipation (Any Package)	
Up to +75°C	470mW
Derates above +75°C by	6mW/°C
Operating Temperature	
Commerical (K Version)	−40°C to +85°C
Industrial (B Version)	−40°C to +85°C
Extended (T Version)	−55°C to +125°C
Storage Temperature Range	−65°C to +150°C
Lead Temperature (Soldering, 10sec)	+300°C

NOTE

[1]Overvoltage at A, EN, $\overline{WR}$, $\overline{RS}$, S or D will be clamped by diodes. Current should be limited to the maximum rating above.

*COMMENT: Stresses above those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. This is a stress rating only and functional operation of the device at these or any other conditions above those indicated in the operational sections of this specification is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

CAUTION:

ESD (electrostatic discharge) sensitive device. The digital control inputs are diode protected; however, permanent damage may occur on unconnected devices subject to high energy electrostatic fields. Unused devices must be stored in conductive foam or shunts. The protective foam should be discharged to the destination socket before devices are inserted.

ORDERING GUIDE

Model[1]	Temperature Range	Package Option[2]
ADG526AKN	−40°C to +85°C	N-28

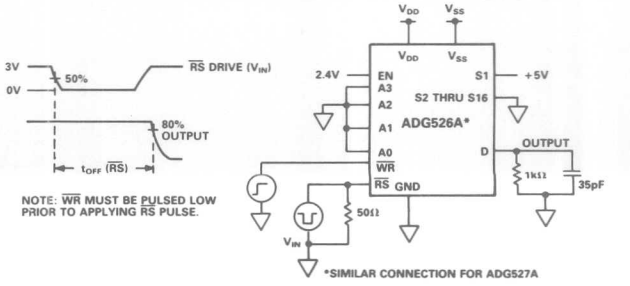
TEST CIRCUIT 8 ENABLE DELAY, t_{ON} (EN), t_{OFF} (EN)

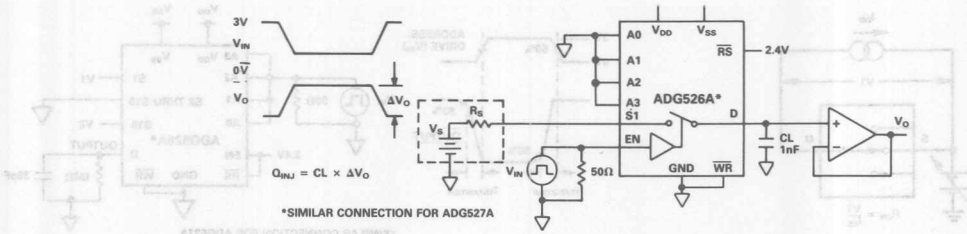
*SIMILAR CONNECTION FOR ADG527A



TEST CIRCUIT 9 WRITE TURN-ON TIME, t_{ON} ($\overline{WR}$)

NOTE: DEVICE MUST BE RESET PRIOR TO APPLYING WR PULSE

*SIMILAR CONNECTION FOR ADG527A



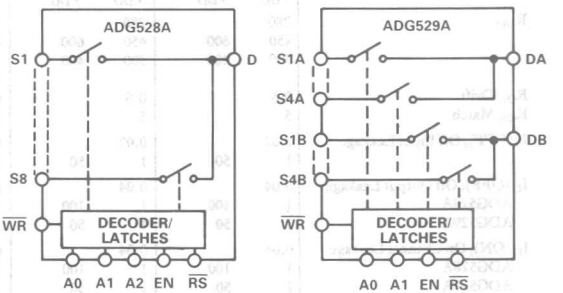
TEST CIRCUIT 10 RESET TURN-OFF TIME, t_{OFF} ($\overline{RS}$)

NOTE: WR MUST BE PULSED LOW PRIOR TO APPLYING RS PULSE.

*SIMILAR CONNECTION FOR ADG527A

5

TERMINOLOGY



R_{ON}	Ohmic resistance between terminals D and S
R_{ON} Match	Difference between the R_{ON} of any two channels
R_{ON} Drift	Change in R_{ON} versus temperature
I_S (OFF)	Source terminal leakage current when the switch is off
I_D (OFF)	Drain terminal leakage current when the switch is off
I_D (ON)	Leakage current that flows from the closed switch into the body
V_S (V_D)	Analog voltage on terminal S or D
C_S (OFF)	Channel input capacitance for "OFF" condition
C_D (OFF)	Channel output capacitance for "OFF" condition
C_{IN}	Digital input capacitance
t_{ON} (EN)	Delay time between the 50% and 90% points of the digital input and switch "ON" condition
t_{OFF} (EN)	Delay time between the 50% and 10% points of the digital input and switch "OFF" condition
$t_{TRANSITION}$	Delay time between the 50% and 90% points of the digital inputs and switch "ON" condition when switching from one address state to another
t_{OPEN}	"OFF" time measured between 50% points of both switches when switching from one address state to another
V_{INL}	Maximum input voltage for Logic "0"
V_{INH}	Minimum input voltage for Logic "1"
I_{INL} (I_{INH})	Input current of the digital input
V_{DD}	Most positive voltage supply
V_{SS}	Most negative voltage supply
I_{DD}	Positive supply current
I_{SS}	Negative supply current

Latched 4/8 Channel Analog Multiplexers

ADG528A/ADG529A

FEATURES
44V Supply Maximum Rating
V_{SS} to V_{DD} Analog Signal Range
Single/Dual Supply Specifications
Wide Supply Ranges (10.8V to 16.5V)
Microprocessor Compatible (100ns $\overline{WR}$ Pulse)
Extended Plastic Temperature Range (−40°C to +85°C)
Low Leakage (20pA typ)
Low Power Dissipation (28mW max)
Available in 16-Lead DIP and 20-Lead LCCC/PLCC Packages
Superior Alternative to:
DG528
DG529

FUNCTIONAL BLOCK DIAGRAMS

5

GENERAL DESCRIPTION

The ADG528A and ADG529A are CMOS monolithic analog multiplexers with 8 channels and dual 4 channels respectively. On-chip latches facilitate microprocessor interfacing. The ADG528A switches one of 8 inputs to a common output depending on the state of three binary addresses and an enable input. The ADG529A switches one of 4 differential inputs to a common differential output depending on the state of two binary addresses and an enable input. Both devices have TTL and 5V CMOS logic compatible digital inputs.

The ADG528A and ADG529A are designed on an enhanced LC^{2}MOS process which gives an increased signal capability of V_{SS} to V_{DD} and enables operation over a wide range of supply voltages. The devices can comfortably operate anywhere in the 10.8V to 16.5V single or dual supply range. These multiplexers also feature high switching speeds and low R_{ON}.

PRODUCT HIGHLIGHTS

1. Single/Dual Supply Specifications with a Wide Tolerance:
   The devices are specified in the 10.8V to 16.5V range for both single and dual supplies.
2. Easily Interfaced:
   The ADG528A and ADG529A can be easily interfaced with microprocessors. The $\overline{WR}$ signal latches the state of the address control lines and the enable line. The $\overline{RS}$ signal clears both the address and enable data in the latches resulting in no output (all switches off). $\overline{RS}$ can be tied to the microprocessor reset pin.
3. Extended Signal Range:
   The enhanced LC^{2}MOS processing results in a high breakdown and an increased analog signal range of V_{SS} to V_{DD}.
4. Break-Before-Make Switching:
   Switches are guaranteed break-before-make so that input signals are protected against momentary shorting.
5. Low Leakage:
   Leakage currents in the range of 20pA make these multiplexers suitable for high precision circuits.

ORDERING GUIDE

Model[1]	Temperature Range	Package Option[2]

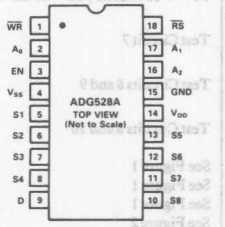
ABSOLUTE MAXIMUM RATINGS*

(T_A = +25°C unless otherwise noted)

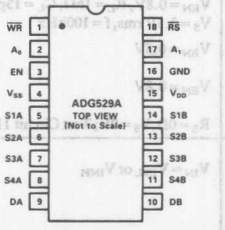
V_{DD} to V_{SS}	44V
V_{DD} to GND	25V
V_{SS} to GND	−25V
Analog Inputs[1]	
Voltage at S, D	V_{SS} −2V to V_{DD} +2V or 20mA, Whichever Occurs First
Continuous Current, S or D	20mA
Pulsed Current S or D	
1ms Duration, 10% Duty Cycle	40mA
Digital Inputs[1]	
Voltage at A, EN, $\overline{WR}$, $\overline{RS}$	V_{SS} −4V to V_{DD} +4V or 20mA, Whichever Occurs First
Power Dissipation (Any Package)	
Up to +75°C	470mW
Derates above +75°C by	6mW/°C
Operating Temperature	
Commerical (K Version)	−40°C to +85°C
Industrial (B Version)	−40°C to +85°C
Extended (T Version)	−55°C to +125°C
Storage Temperature Range	−65°C to +150°C
Lead Temperature (Soldering, 10sec)	+300°C

NOTE
[1]Overvoltage at A, EN, $\overline{WR}$, $\overline{RS}$, S or D will be clamped by diodes. Current should be limited to the maximum rating above.

*COMMENT: Stresses above those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. This is a stress rating only and functional operation of the device at these or any other conditions above those indicated in the operational sections of this specification is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.



CAUTION



ESD (electrostatic discharge) sensitive device. The digital control inputs are diode protected; however, permanent damage may occur on unconnected devices subject to high energy electrostatic fields. Unused devices must be stored in conductive foam or shunts. The protective foam should be discharged to the destination socket before devices are removed.

TIMING DIAGRAMS

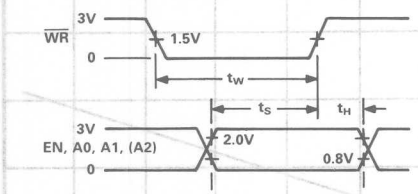

Figure 1

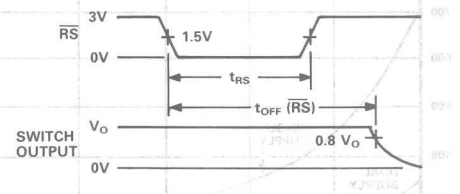
Figure 1 shows the timing sequence for latching the switch address and enable inputs. The latches are level sensitive; therefore, while $\overline{WR}$ is held low, the latches are transparent and the switches respond to the address and enable inputs. This input data is latched on the rising edge of $\overline{WR}$.



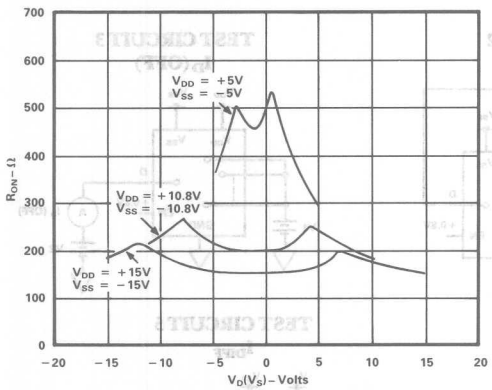


Figure 2

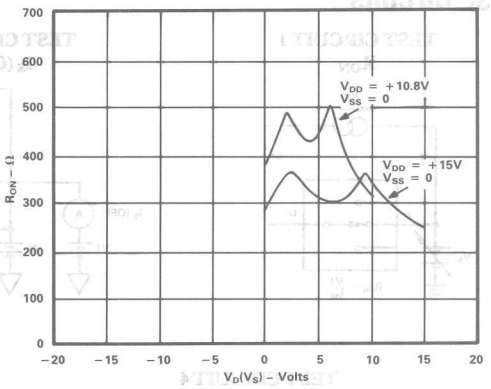
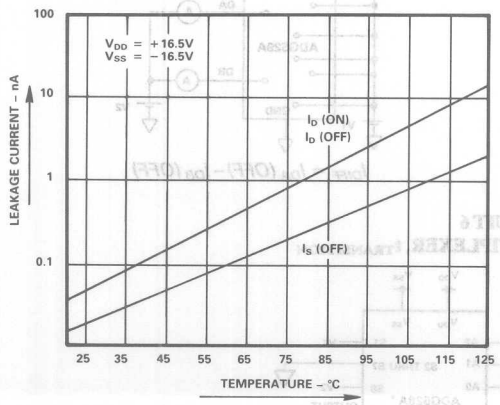
Figure 2 shows the Reset Pulse Width, t_{RS}, and Reset Turn-off Time, t_{OFF} ($\overline{RS}$).

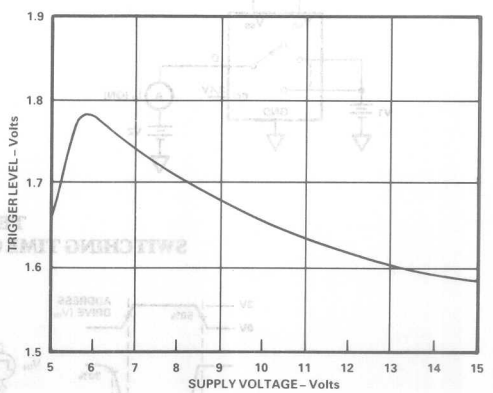


Note: All digital input signals rise and fall times measured from 10% to 90% of 3V. $t_R = t_F = 20ns$.

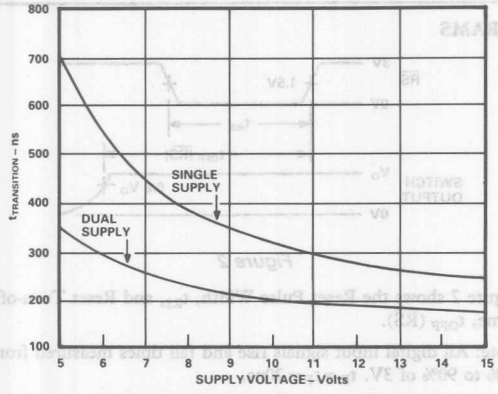
Typical Performance Characteristics



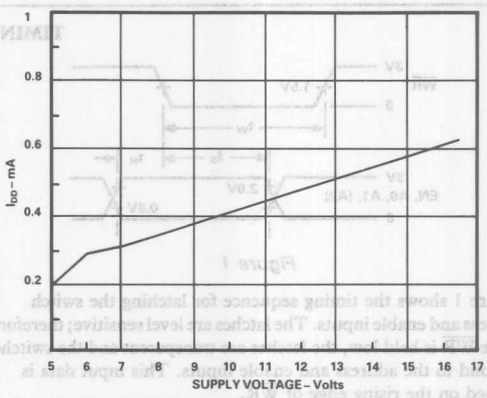
The multiplexers are guaranteed functional with reduced single or dual supplies down to 4.5V.



R_{ON} as a Function of $V_D(V_S)$: Dual Supply Voltage, T_A = +25°C

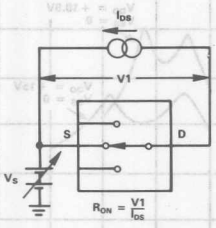


R_{ON} as a Function of $V_D(V_S)$: Single Supply Voltage, T_A = +25°C

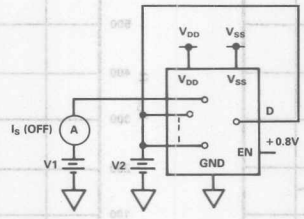


Leakage Current as a Function of Temperature (Note: Leakage Currents Reduce as the Supply Voltages Reduce)

Trigger Levels vs. Power Supply Voltage, Dual or Single Supply, T_A = +25°C



$t_{TRANSITION}$ vs. Supply Voltage: Dual and Single Supplies, T_A = +25°C
(Note: For V_{DD} and $|V_{SS}|$ < 10V; V1 = V_{DD}/V_{SS}, V2 = V_{SS}/V_{DD}. See Test Circuit 6)



I_{DD} vs. Supply Voltage: Dual or Single Supply, T_A = +25°C

TERMINOLOGY

R_{ON}	Ohmic resistance between terminals D and S
R_{ON} Match	Difference between the R_{ON} of any two channels
R_{ON} Drift	Change in R_{ON} versus temperature
I_S (OFF)	Source terminal leakage current when the switch is off
I_D (OFF)	Drain terminal leakage current when the switch is off
I_D (ON)	Leakage current that flows from the closed switch into the body
V_S (V_D)	Analog voltage on terminal S or D
C_S (OFF)	Channel input capacitance for "OFF" condition
C_D (OFF)	Channel output capacitance for "OFF" condition
C_{IN}	Digital input capacitance
t_{ON} (EN)	Delay time between the 50% and 90% points of the digital input and switch "ON" condition
t_{OFF} (EN)	Delay time between the 50% and 10% points of the digital input and switch "OFF" condition
$t_{TRANSITION}$	Delay time between the 50% and 90% points of the digital inputs and switch "ON" condition when switching from one address state to another
t_{OPEN}	"OFF" time measured between 50% points of both switches when switching from one address state to another
V_{INL}	Maximum input voltage for Logic "0"
V_{INH}	Minimum input voltage for Logic "1"
I_{INL} (I_{INH})	Input current of the digital input
V_{DD}	Most positive voltage supply
V_{SS}	Most negative voltage supply
I_{DD}	Positive supply current
I_{SS}	Negative supply current

8-Chan/Dual 4-Chan JFET Analog Multiplexers (Overvoltage & Power Supply Loss Protected)

MUX-08/MUX-24

FEATURES

- JFET Switches Rather Than CMOS
- Low "ON" Resistance ..... 220Ω Typ
- Highly Resistant to Static Discharge Damage
- No SCR Latch-Up Problems
- Digital Inputs Compatible With TTL and CMOS
- 125°C Temperature Tested Dice Available
- MUX-08 Pin Compatible With DG508, HI-508A, IH5108, IH6108, LF11508/12508/13508, AD7506
- MUX-24 Pin Compatible With DG509, HI-509A, IH5208, IH6208, LF11509/12509/13509, AD7507
- Available in Surface Mount Packages
- Available in Die Form

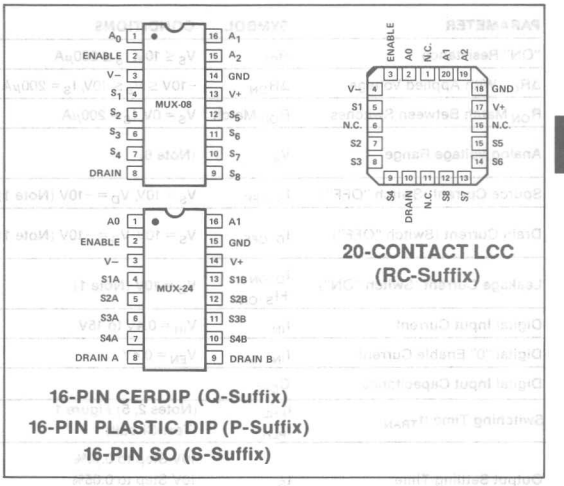
* For devices processed in total compliance to MIL-STD-883, add /883 after part number. Consult factory for 883 data sheet.

† Burn-in is available on commercial and industrial temperature range parts in CerDIP, plastic DIP, and TO-can packages.

†† For availability and burn-in information on SO and PLCC packages, contact your local sales office.

GENERAL DESCRIPTION

The MUX-08 is a monolithic eight-channel analog multiplexer which connects a single output to one of the eight analog inputs depending upon the state of a 3-bit binary address.

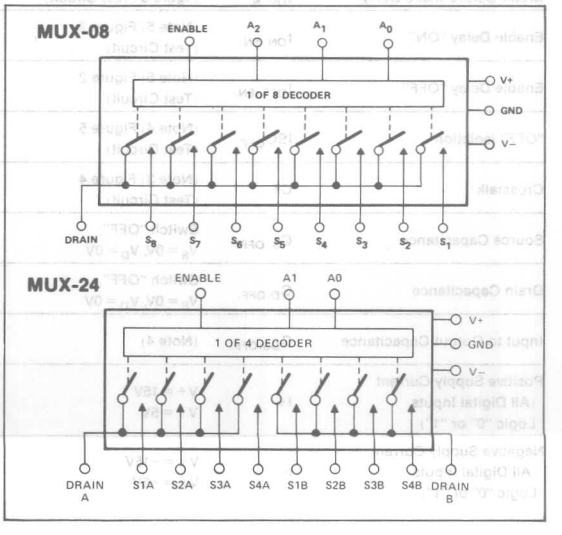


The MUX-24 is a monolithic four-channel differential analog multiplexer configured in a double pole, four-position (plus OFF) electronic switch array. A two-bit binary input address connects a pair of independent analog inputs from each four-channel input section to the corresponding pair of independent analog outputs.

All switches in the MUX-08/MUX-24 are turned OFF by applying logic "0" to the ENABLE pin, thereby providing a package select function.

Fabricated with Precision Monolithics' high performance Bipolar-JFET technology, these devices offer low, constant "ON" resistance, low leakage currents and fast settling time with low crosstalk to satisfy a wide variety of applications. These multiplexers do not suffer from latch-up or static charge blow-out problems associated with similar CMOS parts. The digital inputs are designed to operate from both TTL and CMOS levels while always providing a definite break-before-make action without the need for external pull-up resistors over the full operating temperature range.

For single sixteen-channel and dual eight-channel models, refer to the MUX-16/MUX-28 data sheet.



PIN CONNECTIONS

20-CONTACT LCC (RC-Suffix)

16-PIN CERDIP (Q-Suffix)
16-PIN PLASTIC DIP (P-Suffix)
16-PIN SO (S-Suffix)

FUNCTIONAL DIAGRAMS

ABSOLUTE MAXIMUM RATINGS (Note 1)

Operating Temperature Range
- MUX-08/24-AQ, BQ, BRC ..... –55°C to +125°C
- MUX-02/24-EQ, FQ ..... –25°C to +85°C
- MUX-08/24-EP ..... 0°C to +70°C
- MUX-08/24-FP, FS ..... –40°C to +85°C

Junction Temperature (T_J) ..... –65°C to +150°C
Storage Temperature Range ..... –65°C to +150°C
- P-Suffix ..... –65°C to +125°C

Lead Temperature (Soldering, 60 sec) ..... 300°C
Maximum Junction Temperature ..... 150°C
V+ Supply to V– Supply 36V
Logic Input Voltage ..... (–4V or V–) to V+ Supply
Analog Input Voltage ..... V– Supply –20V to V+ Supply +20V
Maximum Current Through Any Pin 25mA

PACKAGE TYPE	Θ_{JA} (Note 2)	Θ_{JC}	UNITS
16-Pin Hermetic DIP (Q)	100	16	°C/W
16-Pin Plastic DIP (P)	82	39	°C/W
20-Contact LCC (RC)	98	38	°C/W
16-Pin SO (S)	111	35	°C/W

NOTES:
1. Absolute maximum ratings apply to both DICE and packaged parts, unless otherwise noted.
2. Θ_{JA} is specified for worst case mounting conditions, i.e., Θ_{JA} is specified for device in socket for CerDIP, P-DIP, and LCC packages; Θ_{JA} is specified for device soldered to printed circuit board for SO package.

ELECTRICAL CHARACTERISTICS at V+ = +15V, V– = –15V and T_A = 25°C, unless otherwise noted.

Negative Supply Current	I−	All Digital Inputs Logic "0" or "1"		—	—	5	—	—	5	mA

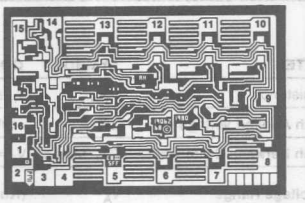
NOTES:



1. Conditions applied to leakage tests insure worst case leakages. Exceeding 11V on the analog input may cause an "OFF" channel to turn "ON".
2. $R_L = 10M\Omega$, $C_L = 10pF$.
3. Crosstalk is measured by driving channel 8 with channel 4 "ON". $R_L = 1M\Omega$, $C_L = 10pF$, $V_S = 5V$ RMS, f = 500kHz.
4. "OFF" isolation is measured by driving channel 8 with ALL channels "OFF". $R_L = 1k\Omega$, $C_L = 10pF$, $V_S = 5V$ RMS, f = 500kHz. C_{DS} is computed from the OFF isolation measurement.
5. Sample tested.
6. Guaranteed by leakage current and R_{ON} tests.
7. Leakage tests are performed only on military temperature grades at 125°C.

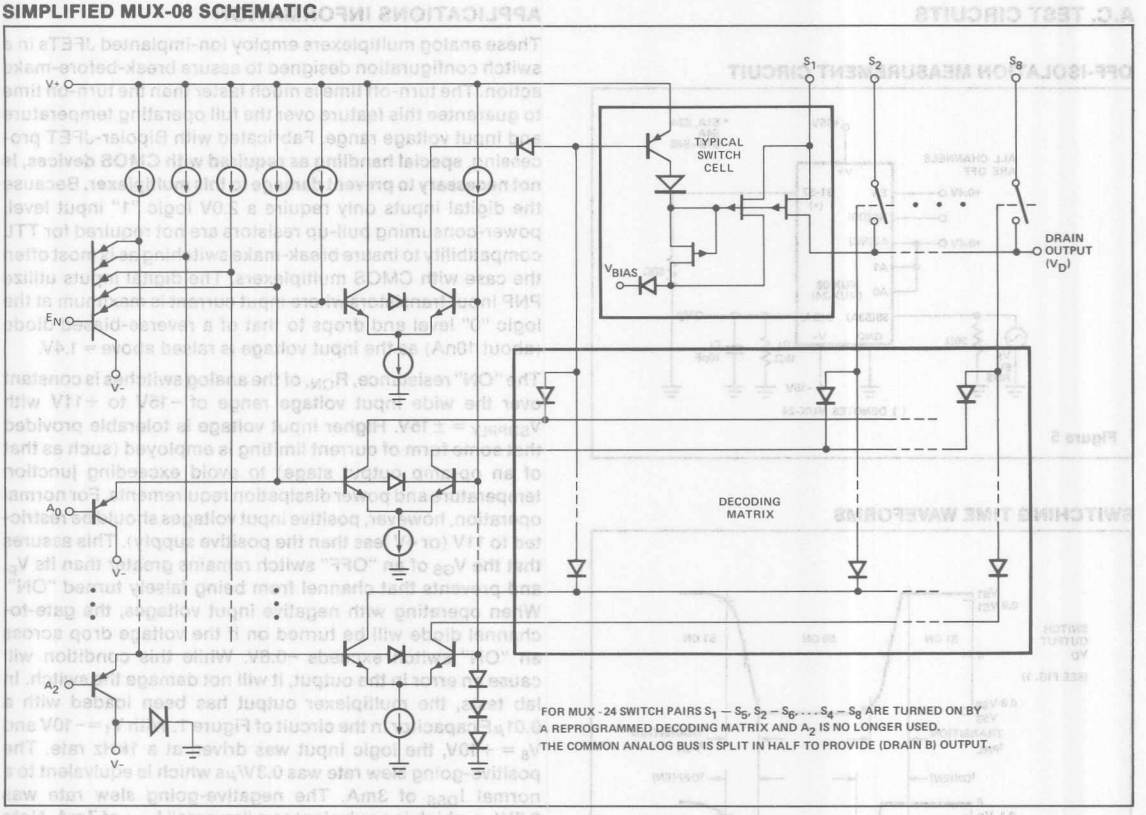
SWITCHING TIME WAVEFORMS

APPLICATIONS INFORMATION

These analog multiplexers employ ion-implanted JFETs in a switch configuration designed to assure break-before-make action. The turn-off time is much faster than the turn-on time to guarantee this feature over the full operating temperature and input voltage range. Fabricated with Bipolar-JFET processing, **special handling as required with CMOS devices, is not necessary to prevent damage to this multiplexer.** Because the digital inputs only require a 2.0V logic "1" input level, power-consuming pull-up resistors are not required for TTL compatibility to insure break-make switching as is most often the case with CMOS multiplexers. The digital inputs utilize PNP input transistors where input current is maximum at the logic "0" level and drops to that of a reverse-biased diode (about 10nA) as the input voltage is raised above ≈ 1.4V.

The "ON" resistance, R_{ON}, of the analog switches is constant over the wide input voltage range of −15V to +11V with $V_{SUPPLY} = \pm 15V$. Higher input voltage is tolerable provided that some form of current limiting is employed (such as that of an op-amp output stage) to avoid exceeding junction temperature and power dissipation requirements. For normal operation, however, positive input voltages should be restricted to 11V (or 4V less than the positive supply). This assures that the V_{GS} of an "OFF" switch remains greater than its V_p, and prevents that channel from being falsely turned "ON". When operating with negative input voltages, the gate-to-channel diode will be turned on if the voltage drop across an "ON" switch exceeds −0.6V. While this condition will cause an error in the output, it will not damage the switch. In lab tests, the multiplexer output has been loaded with a 0.01μF capacitor in the circuit of Figure 1. With $V_1 = -10V$ and $V_8 = +10V$, the logic input was driven at a 1kHz rate. The positive-going slew rate was 0.3V/μs which is equivalent to a normal I_{DSS} of 3mA. The negative-going slew rate was 0.7V/μs which is equivalent to a "reverse" I_{DSS} of 7mA. Note that when switch 1 is first turned "ON" it has a drop of −20V across its terminals. In spite of that fact, the current is limited to approximately twice its normal I_{DSS}.

CROSSTALK AND OFF-ISOLATION



Crosstalk and off-isolation performance is influenced by the type of package selected. Epoxy (P) packaged devices typically exhibit a 12dB improvement in off-isolation (f = 500kHz) performance when compared to ceramic (Q) packaged devices. Epoxy packaged devices typically exhibit a 15dB improvement in crosstalk (f = 500kHz) performance when compared to ceramic (Q) packaged devices.

SINGLE SUPPLY OPERATION OF JFET MULTIPLEXERS

PMI's JFET multiplexers will operate from a single positive supply voltage with the negative supply pin at ground potential. The analog signal range will include ground.

For complete single supply operation information, refer to application note, AN-32.

SIMPLIFIED MUX-08 SCHEMATIC

The simplified MUX-08/MUX-24 schematic shows that logic trip points are determined by two forward diode drops. An internal clamping diode between V– and ground prevents excessive current flow between V+ and ground in the event that V– becomes open circuit. The decoding matrix is accomplished by a programmed diode array. The switch cell consists of P channel JFET's with appropriate blocking diodes which ruggedizes the circuit's overvoltage and supply loss characteristics.

DIFFERENTIAL MULTIPLEXERS

One characteristic unique to differential multiplexers (MUX-24) is the ability to reject common-mode signals from becoming differential error signals. Common-mode rejection is a parameter which defines the amount of rejection in terms of dB. The MUX-24 exhibits a 106dB at 60Hz and 101dB at 400Hz of CMRR using the test circuit of Figure 6.

16-Channel/Dual 8-Channel JFET Analog Multiplexers (Overvoltage Protected)

MUX-16/MUX-28

FEATURES

- JFET Switches Rather Than CMOS
- Highly Resistant To Static Discharge Damage
- No SCR Latch-up Problems
- Low "ON" Resistance — 290Ω Typical
- Low Leakage Current
- Digital Inputs Compatible With TTL and CMOS
- Break-Before-Make Action
- 125° C Temperature-Tested Dice Available
- Overvoltage Protected
- Supply Loss Protection
- MUX-16 Pin Compatible With DG506, HI-506A, AD7506
- MUX-28 Pin Compatible With DG507, HI-507A, AD7507
- Available in Die Form

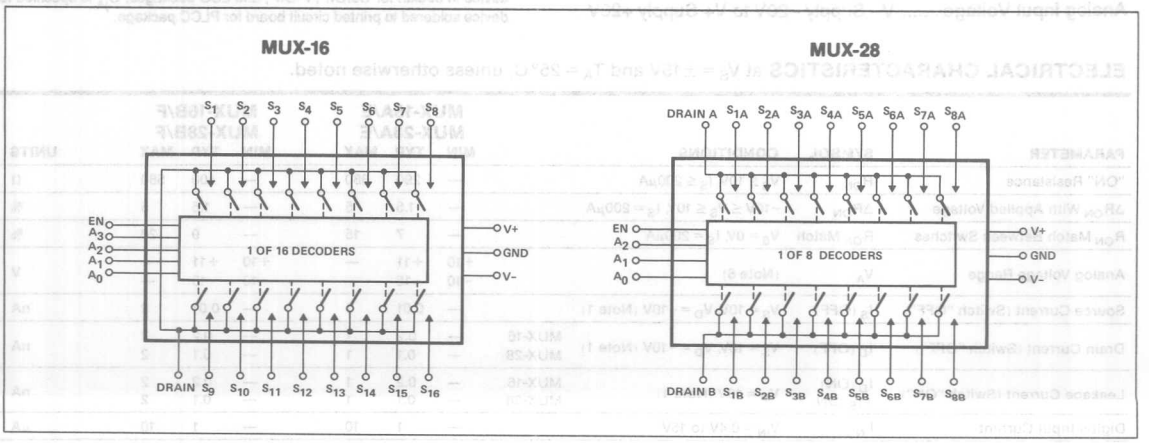
† Burn-in is available on commercial and industrial temperature range parts in CerDIP, plastic DIP, and TO-can packages.

GENERAL DESCRIPTION



The MUX-16 is a monolithic 16-channel analog multiplexer which connects a single output to 1 of the 16 analog inputs depending upon the state of a 4-bit binary address. Disconnection of the output is provided by a logical "0" at the ENABLE input, thereby providing a package selection function.

The MUX-28 is a monolithic 8-channel differential analog multiplexer configured in a double pole, 8-position (plus OFF) electronic switch array. A 3-bit binary input address connects a pair of independent analog inputs from each 8-channel input section to the corresponding pair of independent analog outputs. Disconnection of both inputs is provided by a logical "0" at the ENABLE input, thereby offering a package select function.

Fabricated with Precision Monolithics' high performance Bipolar-JFET technology, these devices offer low, constant "ON" resistance. Performance advantages include low leakage currents and fast settling time with low crosstalk to satisfy a wide variety of applications. These multiplexers do not suffer from latch-up or static discharge blow-out problems associated with similar CMOS parts. The digital inputs are designed to operate from both TTL and CMOS levels while always providing a definite break-before-make action without the need for external pull-up resistors. For single 8-channel and dual 4-channel models, refer to the MUX-08/MUX-24 data sheet.

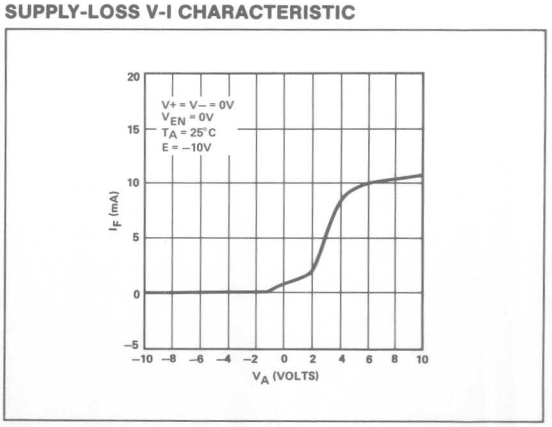
APPLICATIONS INFORMATION

These analog multiplexers employ ion-implanted JFETs in a switch configuration designed to assure break-before-make (B.B.M.) action. The turn-off time is much faster than the turn-on time to guarantee B.B.M. over the full operating temperature and input voltage range. Fabricated with JFET processing rather than CMOS, special handling is not necessary to prevent damage to this multiplexer. Because the digital inputs only require a 2.0V logic "1" input level, power-consuming pullup resistors are not required for TTL compatibility to insure break-before-make switching as is most often the case with CMOS multiplexers. The digital inputs utilize PNP input transistors where input current is maximum at the logic "0" level and drops to that of a reverse-biased diode (about 10nA) as the input voltage is raised above ≈ 1.4V.



The "ON" resistance, R_{ON} of the analog switches is constant over the wide input voltage range of −15V to +11V with $V_{SUPPLY} = \pm 15V$. The overvoltage and supply-loss V-I characteristics shown indicate typical performance when the multiplexer is subjected to abnormal signals. For normal operation, however, positive input voltages should be restricted to 11V (or 4V less than the positive supply). This assures that the V_{GS} of an OFF FET switch remains greater than its V_P, preventing that channel from being falsely turned ON.

When operating with negative input voltages, the gate-to-channel diode will be turned on if the voltage drop across an ON switch exceeds −0.6V. While this condition will cause an error in the output, it will not damage the switch. In lab tests, the multiplexer output has been loaded with a 0.01μF capacitor in the circuit of Figure 1. With $V_1 = -10V$ and $V_{16} = +10V$, the logic input was driven at a 1kHz rate. The positive-going slew rate was 0.3V/μSec which is equivalent to a normal I_{DSS} of 3mA. The negative-going slew rate was 0.7V/μsec which is equivalent to a "reverse" I_{DSS} of 7mA. Note that when switch one (1) is first turned ON it has a drop of −20V across its terminals. In spite of that fact, the current is limited to approximately twice its normal I_{DSS}.

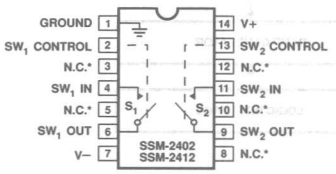
GENERAL DESCRIPTION

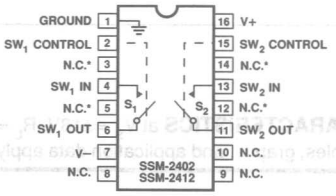
The SSM-2402/2412 are dual analog switches designed specifically for high-performance audio applications. Distortion and noise are negligible over the full audio operating range of 20Hz to 20kHz at signal levels of up to $10V_{RMS}$. The SSM-2402/2412 offer a monolithic integrated alternative to expensive and noisy relays or complex discrete JFET circuits. Unlike conventional general-purpose CMOS switches, the SSM-2402/2412 provide superb fidelity without audio "clicks" during switching.

Conventional TTL or CMOS logic can be used to control the switch state. No external pull-up resistors are needed. A "T" configuration provides superb OFF-isolation and true bilateral operation. The analog inputs and outputs are protected against overload and overvoltage.



An important feature is the guaranteed "break-before-make" for **all** units, even IC-to-IC. In large systems with multiple switching channels, all separate switching units must open before any switch goes into the ON-state. With the SSM-2402/2412, you can be certain that multiple circuits will all break-before-make.

The SSM-2402/2412 represent a significant step forward in audio switching technology. Distortion and switching noise are significantly reduced in the new SSM-2402/2412 bipolar-JFET switches relative to CMOS switching technology. Based on a new circuit topology that optimizes audio performance, the SSM-2402/2412 make use of a proprietary bipolar-JFET process with thin-film resistor network capability. Nitride capacitors, which are very area efficient, are used for the proprietary ramp generator that controls the switch resistance transition. Very wide bandwidth amplifiers control the gate-to-source voltage over the full audio operating range for each switch. The ON-resistance remains constant with changes in signal amplitude and frequency, thus distortion is very low, less than 0.01% Max.



The SSM-2402 is the first analog switch truly optimized for high-performance audio applications. For broadcasting and other switching applications which require a faster switching time, we recommend the SSM-2412 – a dual analog switch with one-third of the switching time of the SSM-2402.

NOTES:
1. "V_{IL}" is the Logic Control Input.
2. Although not recommended, using unbalanced supplies with the positive rail in excess of 20V will result in an increased digital input high threshold. The threshold is set to 9.3% of the positive supply voltage.
3. Current tested at $V_{IN} = 0V$. This is the worst case condition.
4. Guaranteed by R_{ON} test condition.
5. Turn-ON Time is measured from the time the logic input reaches the 50% point to the time the output reaches 50% of the final value.
6. Turn-OFF time is measured from the time the logic input reaches the 50% point to the time the output reaches 50% of the initial value.
7. Switch is guaranteed by design to provide break-before-make operation.
8. THD guaranteed by design and dynamic R_{ON} testing.

APPLICATIONS INFORMATION

FUNCTIONAL SECTIONS

Each half of the SSM-2402/2412 are made up of three major functional blocks:

1. **"T" Switch**
   Consists of JFET switches S_1 and S_2 in series as the main switches and switch S_3 as a shunt.

2. **Ramp Generator**
   Generates a ramp voltage on command of the Control Input (see Figure 1). A LOW-to-HIGH TTL input at Control Input initiates a ramp that goes from approximately –7V to +7V in 12ms for the SSM-2402, and 4ms for the SSM-2412. Conversely, a HIGH-to-LOW TTL transition at Control Input will cause a downward ramp from approximately +7V to –7V in 12ms for the SSM-2402, and 4ms for the SSM-2412. The Ramp Generator also supplies the +3V and –3V reference levels for Switch Control.

3. **Switch Control**
   The ramp from the Ramp Generator section is applied to two differential amplifiers (DA_1 and DA_2) in the Switch Control block. (See Simplified Schematic). One amplifier is referenced to –3V and the other is referenced to +3V. Switch Control Outputs are:

   – **Main Switch Control** – Drives two 0.25mA current sources that control the inverting inputs of each op amp. When ON, the current sources cause a gate-to-source voltage of approximately 2.5V which is sufficient to turn off S_1 and S_2. When the current sources from Main Switch Control are OFF, each op amp acts as a unity-gain follower ($V_{GS} = 0$) and both switches (S_1 and S_2) will be ON.

   – **Shunt Switch Control** – Controls the Shunt Switch of the "T" configuration.

SWITCH OPERATION

To see how the SSM-2402/2412 switches work, first consider an OFF-to-ON transition. The Control Input is initially LOW and the Ramp Output is at approximately –7V. The Main Switch Control is HIGH which drives current sources Q_3 and Q_4 to 0.25mA each. These currents generate 2.5V gate-to-source back bias for each JFET switch (S_1 and S_2) which holds them OFF.

The Shunt Switch Control is negative which holds the shunt JFET S_3 ON. Undesired feedthrough signals in the series JFET switches S_1 and S_2 are shunted to the negative supply rail through S_3.

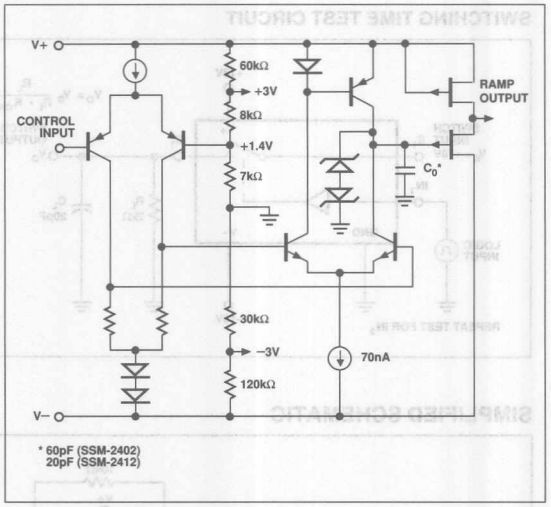

FIGURE 1: *RAMP Generator*

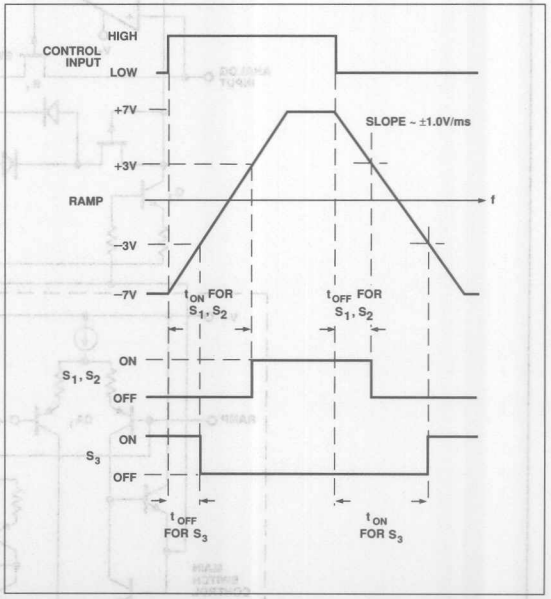

FIGURE 2: *Switch Control*

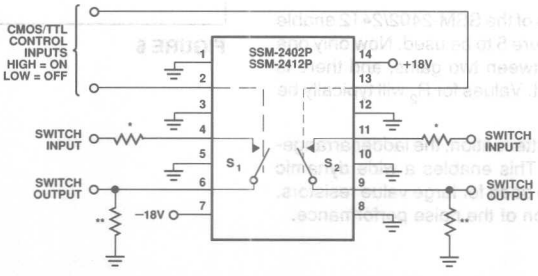
When the Control Input goes from LOW to HIGH, the Ramp Generator slews in the positive direction as shown in Figure 2. When the ramp goes more positive than –3V, the Shunt Switch Control is pulled positive by differential amplifier DA_2 which thereby puts shunt switch S_3 into the OFF state. Note that S_1 and S_2 are still OFF, so at this time all three switches in the "T" are OFF.

When the Ramp Output reaches +3V, and the drive for the Main Switch Control output is gated OFF by differential amplifier DA_1, current sources Q_3 and Q_4 go to the OFF state and the V_{GS} of each main switch goes to zero. The high-speed op amp followers provide essentially zero gate-to-source voltage over the full audio signal range; this in turn assures a constant low impedance in the ON state over the full audio signal range. Total time to turn on the SSM-2402 switch is approximately 10.0ms and 3.5ms for the SSM-2412.

In systems using a large number of separate switches, there are advantages to having faster switching into OFF state than into the ON state. Break-before-make can be maintained at the system level. To see how the SSM-2402/2412 guarantee break-before-make, consider the ON-to-OFF transition.

A Control Input LOW initiates the ON-to-OFF transition. The Ramp Generator integrates down from approximately +7V towards –7V. As the ramp goes through +3V, the comparator controlling the Main Switches (S_1 and S_2) goes HIGH and turns on current sources Q_3 and Q_4 which thereby puts S_1 and S_2 into the OFF state. At this time, all switches in the "T" are OFF. When the ramp integrates down to –3V, the Shunt Switch Control changes state and pulls shunt switch S_3 into the ON state. This completes the ON-to-OFF transistion; S_1 and S_2 are OFF, and S_3 is ON to shunt away any undesired feedthrough. Note though that the ON-to-OFF time for main switches S_1 and S_2 is only the time interval required for the ramp to go from +7V to +3V, about 4ms for the SSM-2402, and 1.5ms for the SSM-2412. The time to turn on is about 2.5 times as long as the time to turn off.

The SSM-2402/2412 are much more than a simple single solid-state switches. The "T" configuration provides superb OFF-isolation through shunting of feedthrough via shunt switch S_3. Break-before-make is inherent in the design. The ramp provides a controlled gating action that softens the ON/OFF transitions. Distortion is minimized by holding zero gate-to-source voltage for the two main FET switches, S_1 and S_2, using the two op amp followers. Figure 3 shows a distortion comparison between the SSM-2402 and a typical CMOS switch. In summary, the SSM-2402/2412 are designed specifically for high-performance audio system usage.



OVERVOLTAGE PROTECTION

The SSM-2402/2412 are designed to guarantee correct operation with inputs of up to ±14.2V with ±18V supplies. The switch input should never be forced to go beyond the supply rails. In the OFF condition, if the inputs exceeds +14.2V, there is a risk of turning the respective input pass FET "ON." When the input voltage rises to within 3.8V of the positive supply, the op amp follower saturates and will not be able to maintain the full 2.5V of back bias on the gate-to-source junction. Under this condition, current will flow from the input through the shunt FET to the negative supply. This current is substantial, but is limited by the FET I_{DSS}. Although this current will not damage the device, there is a danger of also turning on the output pass FET, especially if the output is close to the negative rail.

This risk of signal "breakthrough" for inputs above +14.2V can be eliminated by using a source resistor of 100-500Ω in series with the analog input to provide additional current limiting.

Near the negative supply, transistors Q_3 and Q_4 saturate and can no longer keep the switch OFF. Signal breakthrough cannot happen, but the danger here is latch-up via a path to V– through the shunt FET. Additional circuitry (not shown) has been incorporated to turn OFF the shunt FET under these conditions, and the potential for latch-up is thereby eliminated.

TYPICAL CONFIGURATION

* OPTIONAL INPUT RESISTORS
SEE SECTION ON OVERVOLTAGE PROTECTION

** OPTIONAL LOAD RESISTORS
LOWER VALUES WILL MINIMIZE "CLICKS" BUT WITH A $10V_{RMS}$ INPUT
IT IS RECOMMENDED THAT THEY BE GREATER THAN 2kΩ

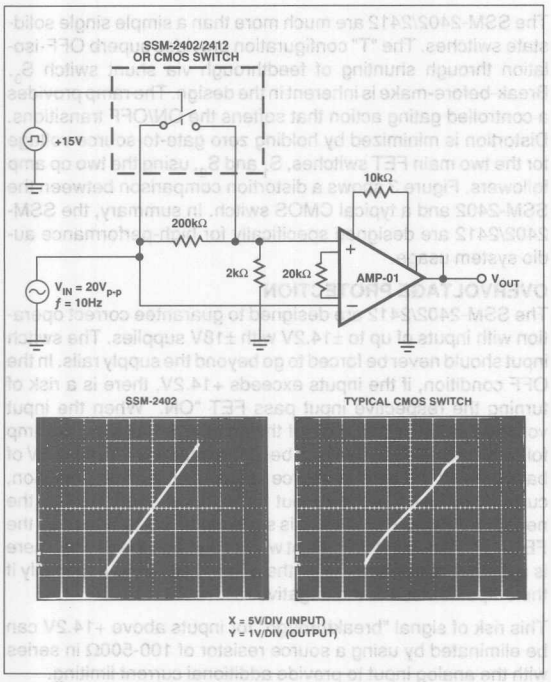


FIGURE 3: *Comparison of the SSM-2402 and Typical CMOS Switch for Distortion*

DIGITALLY-CONTROLLED ATTENUATOR

Figure 4 shows the usual approach to digitally-controlled attenuation. With S_1 closed, the signal passes unattenuated to the output. With S_1 open and S_2 closed, the signal is attenuated by R_1 and R_2. The advantage of this configuration is that the attenuator current does not have to flow through the switches. The disadvantage is that the output is undefined during the switching period, which can be several milliseconds.

The low distortion characteristics of the SSM-2402/2412 enable the alternate arrangement of Figure 5 to be used. Now only one switch is required to change between two gains, and there is always a signal path to the output. Values for R_2 will typically be in the low kilohm range.

For more gain steps and higher attenuation, the ladder arrangement of Figure 6 can be used. This enables a wide dynamic range to be achieved without the need for large value resistors, which would result in degradation of the noise performance.

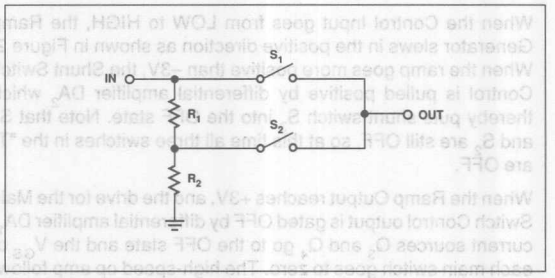

FIGURE 4

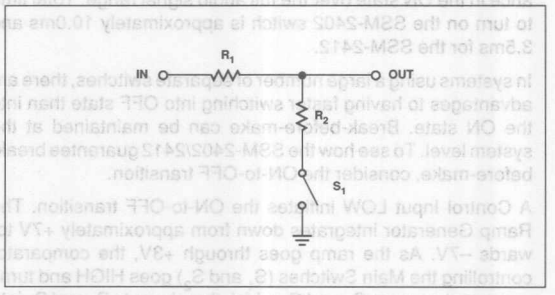

FIGURE 5

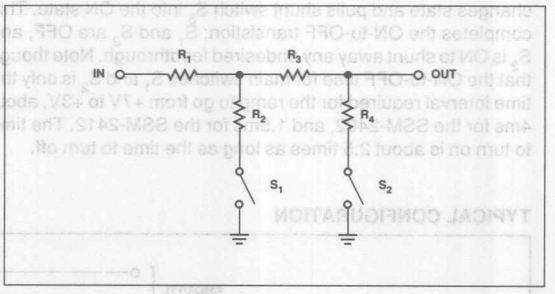

FIGURE 6

HIGH-PERFORMANCE STEREO ROUTING SWITCHER

The SSM-2402 Dual Audio Switch comprises the nucleus for this 16 channels-to-one high performance stereo audio routing switcher, which features negligible noise and low distortion over the frequency range of 20Hz to 20kHz. This performance is achieved even while driving 600Ω loads at signal levels up to +30dBu.

The SSM-2402 affords a much simplified electrical design and printed circuit board layout, along with reduced manufacturing cost, when compared with discrete JFET circuits of similar performance. The electrical performance of the design described is vastly superior to CMOS switch designs, which are more prone to failure resulting from electrical static discharge.

The switching control of the SSM-2402 may be activated by conventional mechanical switches or 5 volt TTL or CMOS logic circuits. The application shown utilizes a simple mechanical control switch for illustration purposes only. Many diverse X/Y control schemes, destination control, or computer controlled designs can be utilized.

The "T" configuration of the SSM-2402 switch provides excellent ON-OFF isolation. The SSM-2402 also features 7ms ramped turn on and 4ms ramped turn off for click-free switching. Additionally, the switch has a break-before-make switching sequence. Both features become significant in large audio switching systems where the audio path can pass through multiple switching elements. Such controlled switching is very important in large systems used in broadcast program switching or in production work.

The application circuit design also employs the SSM-2015 balanced input amplifier (Figure 7). The input impedance is high (≈100kΩ), balanced or unbalanced. The input circuit incorporates a single pole RFI filter with a cutoff frequency set at 145kHz. In addition, the input circuit attenuates the signal by 25dB and extends the common-mode input voltage range to ±98 volts peak, with common-mode rejection greater than 70dB from 20Hz to 20kHz. The SSM-2015 is set to produce a 15dB gain. The signal drive level into the SSM-2402 switch is then +10dBu with a +20dBu input level and +14dBu peak, well within

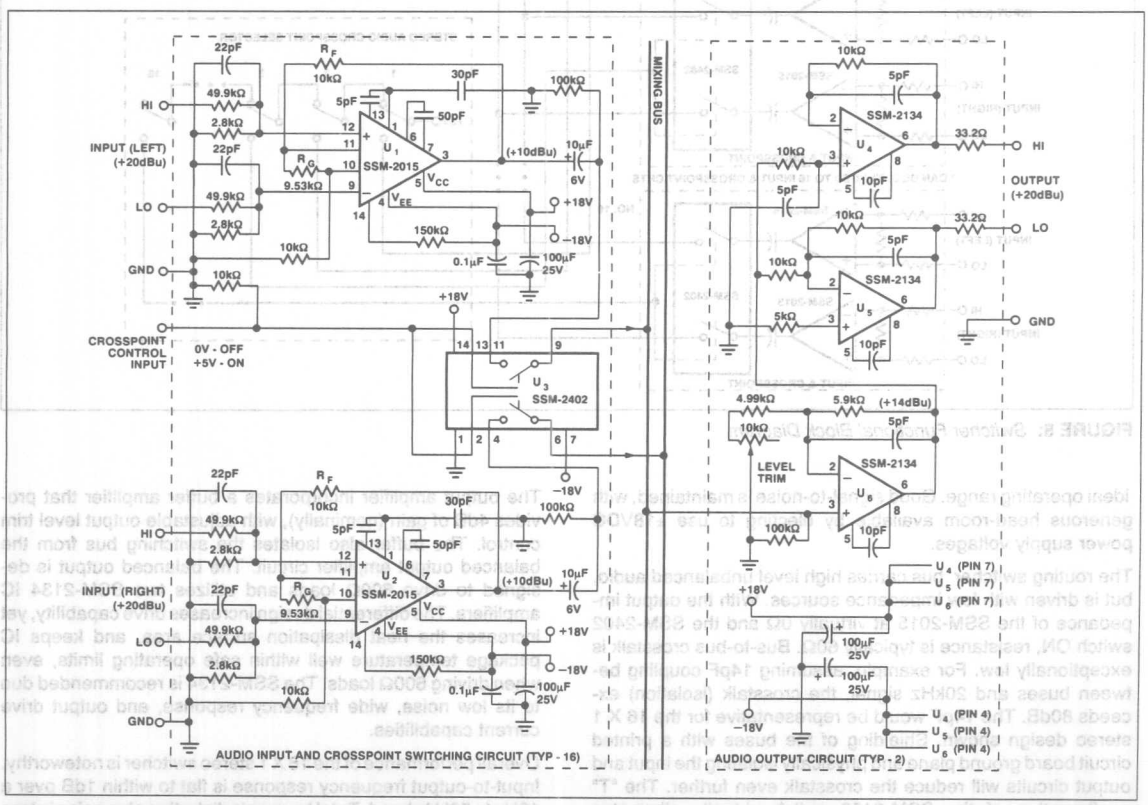

FIGURE 7: *Switcher Schematic*

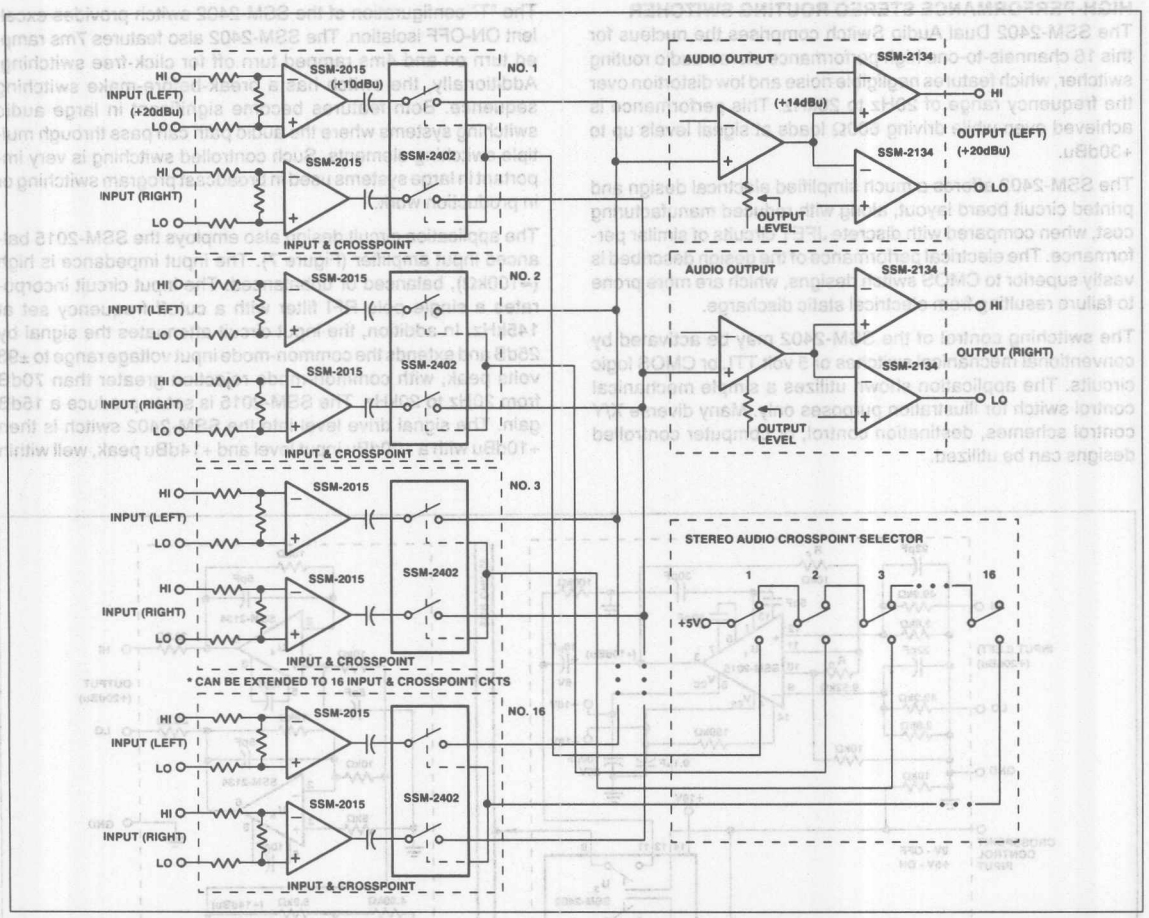

FIGURE 8: *Switcher Functional Block Diagram*

ideal operating range. Good signal-to-noise is maintained, with generous head-room available by electing to use ±18VDC power supply voltages.

The routing switcher bus carries high level unbalanced audio, but is driven with low impedance sources. With the output impedance of the SSM-2015 at virtually 0Ω and the SSM-2402 switch ON, resistance is typically 60Ω. Bus-to-bus crosstalk is exceptionally low. For example, assuming 14pF coupling between buses and 20kHz signal, the crosstalk (isolation) exceeds 80dB. The 14pF would be representative for the 16 X 1 stereo design shown. Shielding of the buses with a printed circuit board ground plane and physically isolating the input and output circuits will reduce the crosstalk even further. The "T" configuration of the SSM-2402 switch virtually eliminates crosstalk between the various input signal sources.

The output amplifier incorporates a buffer amplifier that provides 4dB of gain (nominally), with adjustable output level trim control. The buffer also isolates the switching bus from the balanced output amplifier circuit. The balanced output is designed to drive 600Ω loads and utilizes two SSM-2134 IC amplifiers. The differential design increases drive capability, yet increases the heat dissipation surface area, and keeps IC package temperature well within safe operating limits, even when driving 600Ω loads. The SSM-2134 is recommended due to its low noise, wide frequency response, and output drive current capabilities.

Overall performance of the 16 X 1 stereo switcher is noteworthy. Input-to-output frequency response is flat to within 1dB over a 10Hz to 50kHz band. Total harmonic distortion plus noise is less than 0.03%, from 20Hz to 20kHz. SMPTE intermodulation distortion is less than 0.02%. The use of ±18VDC power supplies produces a +30dBm clip level, even when driving 600Ω loads.

TABLE 1: Circuit Performance Specifications

Max Input Level	+30dBu
Input Impedance, Unbalanced	100kΩ
Input Impedance, Balanced	200kΩ
Common-Mode Rejection (20Hz to 20kHz)	>70dB
Common-Mode Voltage Limit	±98V Peak
Max Output Level	+30dBu/dBm
Output Impedance	67Ω
Gain Control Range	±2dB
Output Voltage Slew Rate	6V/μs
Frequency Response (±0.05dB)	20Hz to 20kHz
Frequency Response (±0.5dB)	10Hz to 50kHz

- "Clickless" Bilateral Audio Switching
- Four SPST Switches in a 16-Pin Package
- Ultralow THD+N: 0.0009% @ 1 kHz (V_{IN} = 2 V rms, R_L = 100 kΩ)
- Low Charge Injection: 35 pC
- High OFF Isolation: 100 dB
- Low ON Resistance: 28 Ω
- Low Supply Current: 900 μA
- Single or Dual Supply Operation: +11 V to +24 V or ±5.5 V to ±12 V
- Guaranteed Break-Before-Make
- TTL and CMOS Compatible Logic Inputs
- Low Cost-Per-Switch

PIN CONNECTIONS

NC = NO CONNECT

PRELIMINARY TECHNICAL DATA

GENERAL DESCRIPTION

The SSM-2404 integrates four SPST analog switches in a single 16-pin package. Developed specifically for high performance audio applications, distortion and noise are negligible over the full operating range of 20 Hz to 20 kHz. With very low charge injection of 35 pC, "clickless" audio switching is possible, even under the most demanding conditions.

Switch control is realized by conventional TTL or CMOS logic. Guaranteed "break-before-make" operation assures that all switches in a large system will open before any switch reaches the ON state.

Single or dual supply operation is possible. Additional features include 100 dB OFF isolation, 28 Ω ON resistance, and a wide signal handling range. Although optimized for virtual ground switching, the SSM-2404 maintains good audio performance even under low load impedance conditions.

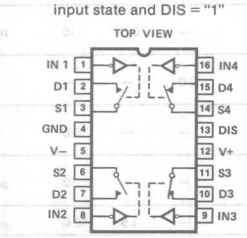
Quad SPST JFET Analog Switch



SW-06

FEATURES

- **Two Normally Open and Two Normally Closed SPST Switches with Disable**
- **Switches can be Easily Configured as a Dual SPDT or a DPDT**
- **Highly Resistant to Static Discharge Destruction**
- **Higher Resistance to Radiation Than Analog Switches Designed with MOS Devices**
- **Guaranteed R_{ON} Matching ..... 10% Max**
- **Guaranteed Switching Speeds ..... T_{ON} = 500ns Max**
  T_{OFF} = 400ns Max
- **Guaranteed Break-Before-Make Switching**
- **Low "ON" Resistance ..... 80Ω Max**
- **Low R_{ON} Variation from Analog Input Voltage 5%**
- **Low Total Harmonic Distortion 0.01%**
- **Low Leakage Currents at High Temperature:**
  T_A = 125° C ..... 100nA Max
  T_A = 85° C ..... 30nA Max
- **Digital Inputs TTL/CMOS Compatible and Independent of V+**
- **Improved Specifications and Pin Compatible to LF-11333/13333**
- **Dual or Single Power Supply Operation**
- **Available in Die Form**

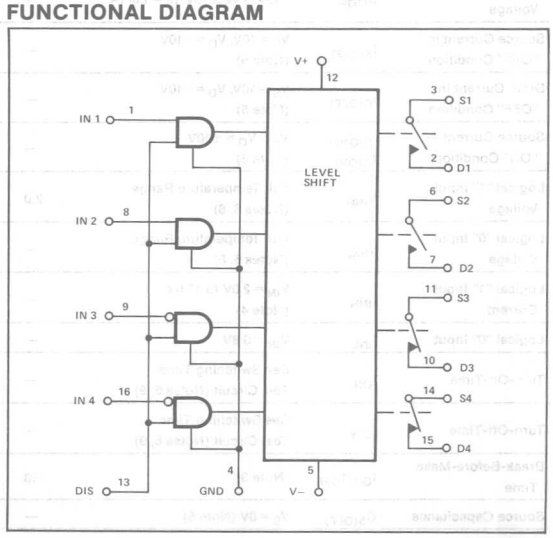
GENERAL DESCRIPTION



The SW-06 is a four channel single-pole, single-throw analog switch that employs both bipolar and ion-implanted FET devices. The SW-06 FET switches use bipolar digital logic inputs which are more resistant to static electricity than CMOS devices. Ruggedness and reliability are inherent in the SW-06 design and construction technology.

Increased reliability is complemented by excellent electrical specifications. Potential error sources are reduced by minimizing "ON" resistance and controlling leakage currents at high temperatures. The switching FET exhibits minimal R_{ON} variation over a 20V analog signal range and with power supply voltage changes. Operation from a single positive power supply voltage is possible. With V+ = 36V, V– = 0V, the analog signal range will extend from ground to +32V.

PNP logic inputs are TTL and CMOS compatible to allow the SW-06 to upgrade existing designs. The logic "0" and logic "1" input currents are at micro-ampere levels reducing loading on CMOS and TTL logic.

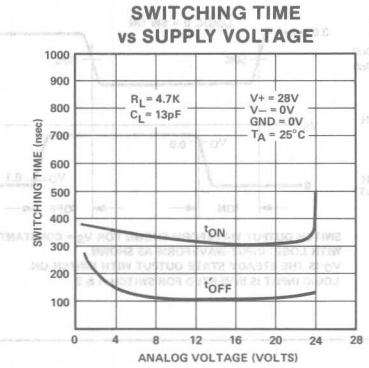
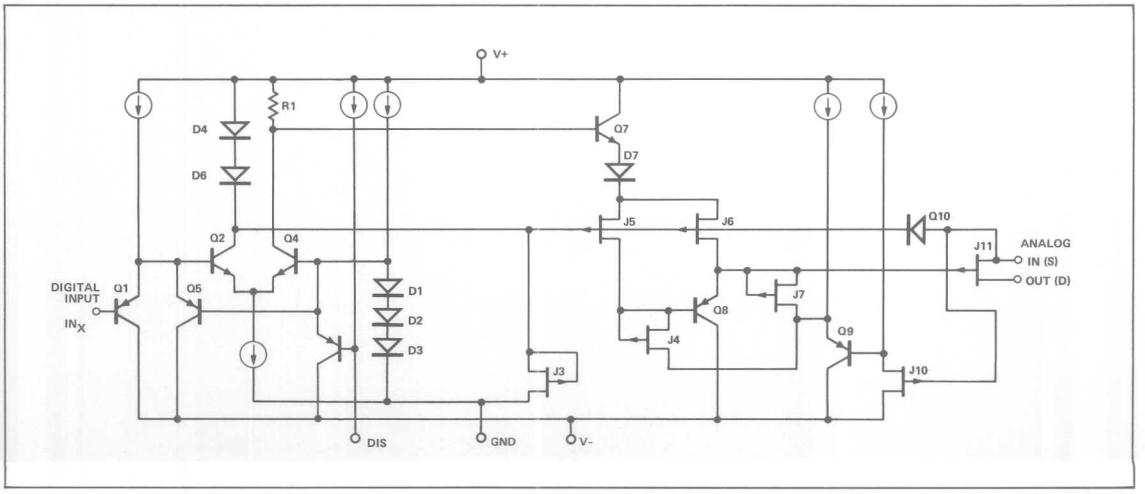
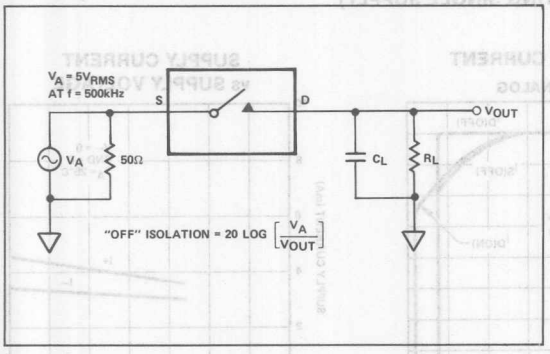
OVERVOLTAGE CHARACTERISTICS



TYPICAL PERFORMANCE CHARACTERISTICS (OPERATING SINGLE SUPPLY)





NOTE: These single-supply-operation characteristic curves are valid when the negative power supply V– is tied to the logic ground reference pin "GND". TTL input compatibility is still maintained when "GND" is the same potential as the TTL ground. t'_{OFF} is measured from 50% of logic input waveform to 0.9 V_O. The analog voltage range extends from 0 to V+ –4V, the switch will no longer respond to logic control when V_A is within 4 volts of V+.

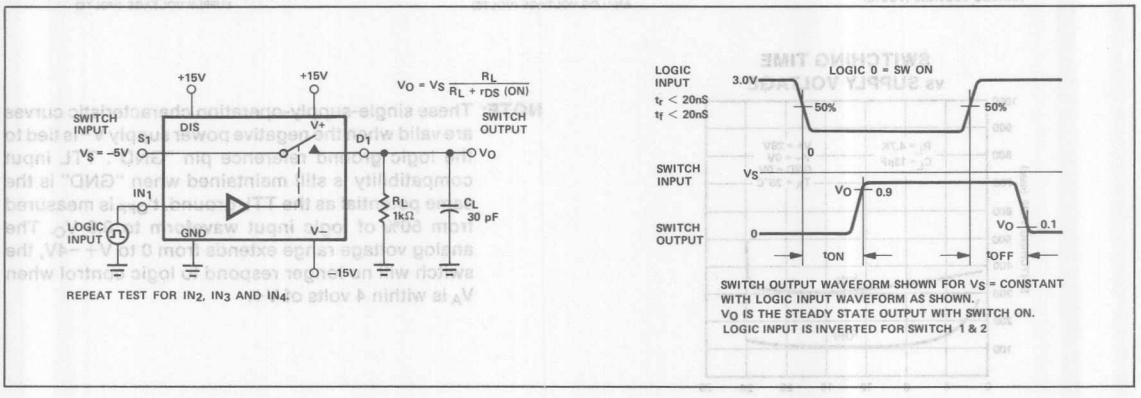
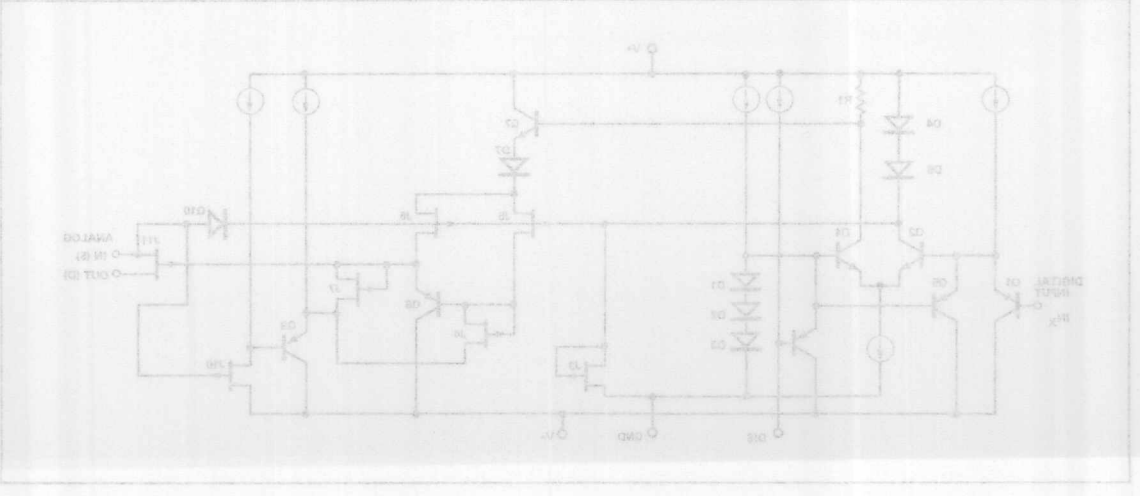
SW-06



OFF ISOLATION TEST CIRCUIT



CROSSTALK TEST CIRCUIT

SWITCHING TIME TEST CIRCUIT

ANALOG CURRENT

The analog switches in the ON state are JFETs biased in their triode region and act as switches for analog current up to the I_A specification (see plot of I_{DS} vs V_{DS}). Some applications require pulsed currents exceeding the I_A spec. For example, an integrator reset switch discharging a shunt capacitor will produce a peak current of $I_{A(PEAK)} = V_{CAP}/R_{DS(ON)}$. In this application, it is best to connect the source to the most positive end of the capacitor, thereby achieving the lowest switch resistance and fastest reset times. The switch can easily handle any amount of capacitor discharge current subject only to the maximum heat dissipation of the package and the maximum operating junction temperature from which repetition rates can be established.

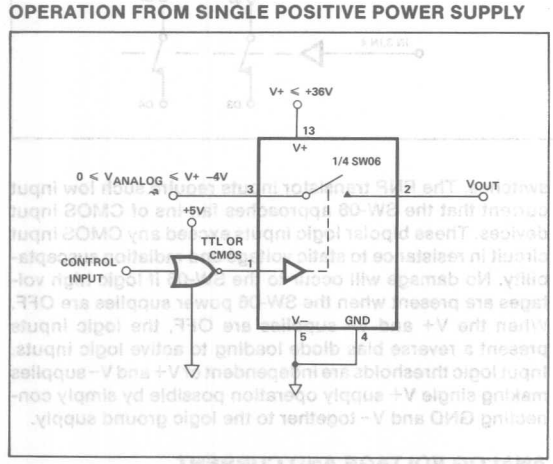
SWITCHING

Switching time t_{ON} and t_{OFF} characteristics are plotted versus V_{ANALOG} and temperature. In all cases, t_{OFF} is designed faster than t_{ON} to insure a break-before-make interval for SPDT and DPDT applications. The disable input (DIS) has the same switching times (t_{ON} and t_{OFF}) as the logic inputs (IN_X).

Switching transients occurring at the source and drain contacts results from AC coupling of the switching FETs gate-to-source and gate-to-drain coupling capacitance. The switch turn ON will cause a negative going spike to occur and the turn OFF will cause a positive spike to occur. These spikes can be reduced by additional capacitance loading, lower values of R_L, or switching an additional switch (with its extra contact floating) to the opposite state connected to the spike sensitive node.

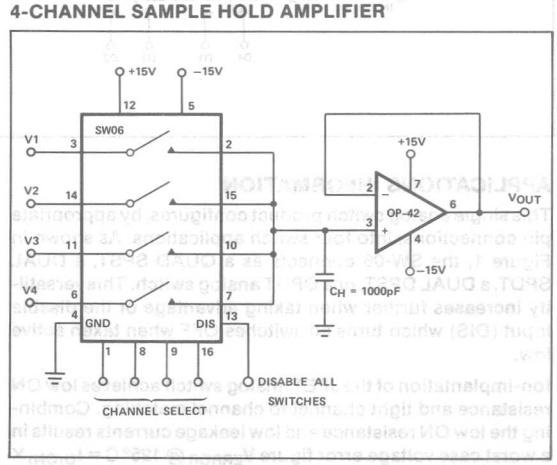
DISABLE NODE

This TTL compatible node is similar to the logic inputs IN_X but has an internal 2μA current source pull-up. If disable is left unconnected, it will assume the logic "1" state, then the state of the switches is controlled only by the logic inputs IN_X.

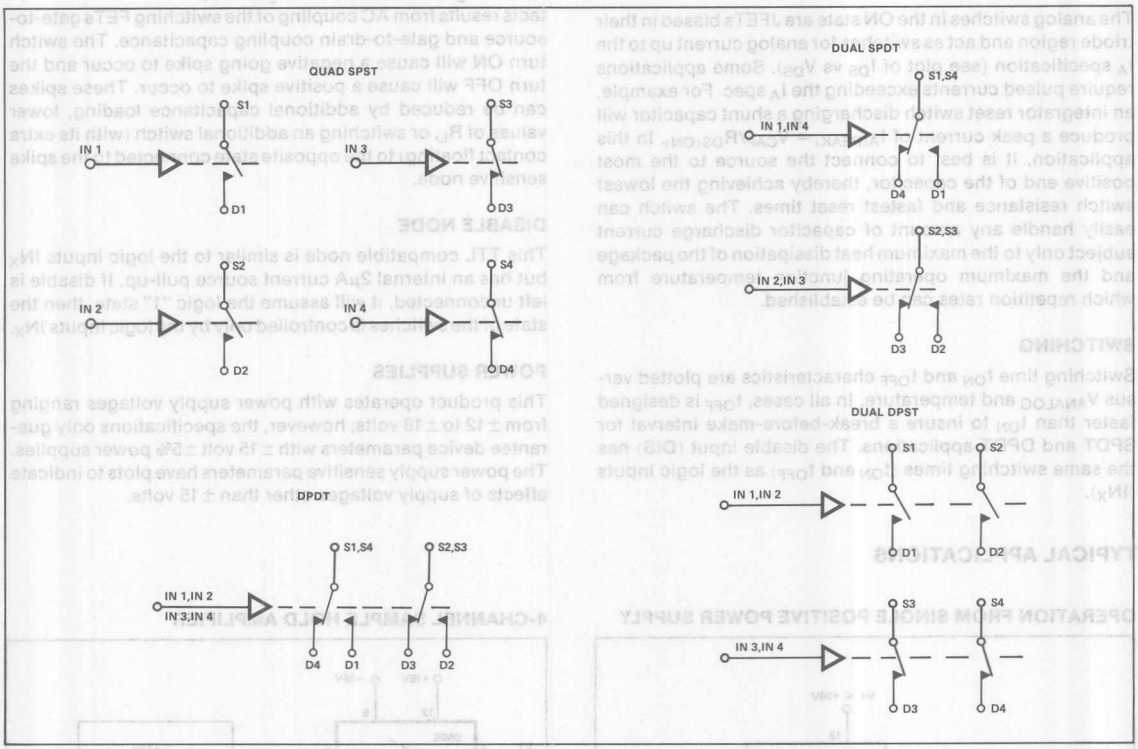


POWER SUPPLIES

This product operates with power supply voltages ranging from ±12 to ±18 volts; however, the specifications only guarantee device parameters with ±15 volt ±5% power supplies. The power supply sensitive parameters have plots to indicate effects of supply voltages other than ±15 volts.



5



TYPICAL APPLICATIONS

OPERATION FROM SINGLE POSITIVE POWER SUPPLY

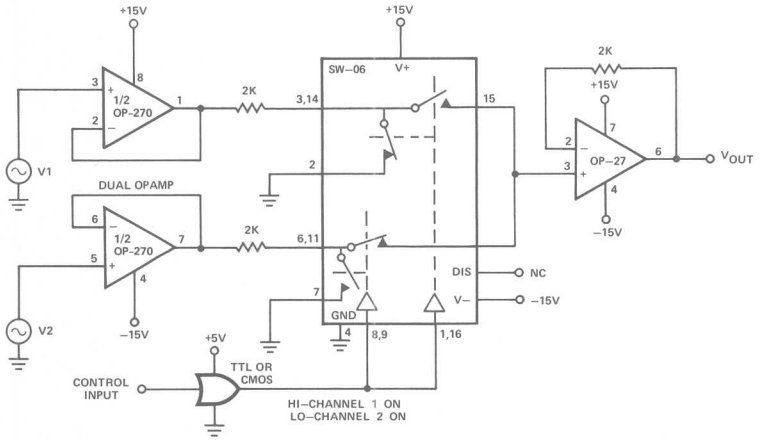
4-CHANNEL SAMPLE HOLD AMPLIFIER

APPLICATIONS INFORMATION

This single analog switch product configures, by appropriate pin connections, into four switch applications. As shown in Figure 1, the SW-06 connects as a QUAD SPST, a DUAL SPDT, a DUAL DPST, or a DPDT analog switch. This versatility increases further when taking advantage of the disable input (DIS) which turns all switches OFF when taken active low.

Ion-implantation of the JFET analog switch achieves low ON resistance and tight channel to channel matching. Combining the low ON resistance and low leakage currents results in a worst case voltage error figure V_{ERROR} @ 125° C = $I_{D(ON)} \times R_{SD(ON)} = 100nA \times 100\Omega = 11$ microvolts. This amount of error is negligible considering dissimilar-metal thermally-induced offsets will be in the 5 to 15 microvolt range.

LOGIC INPUTS

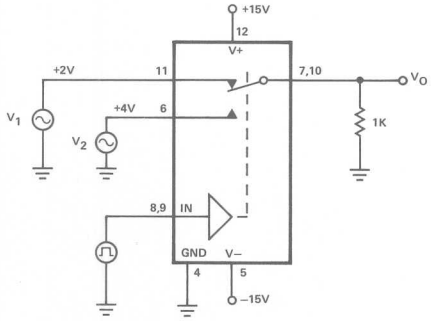


The logic inputs (IN_X) and disable input (DIS) are referenced to a TTL logic threshold value of two forward diode drops (1.4V at 25° C) above the GND terminal. These inputs use PNP transistors which draw maximum current at a logic "0" level and drops to a leakage current of a reverse biased diode as the logic input voltage raises above 1.4 volts. Any logic input voltage greater than 2.0 volts becomes logic "1", less than 0.8 volts becomes logic "0" resulting in full TTL noise immunity not available from similar CMOS input analog switches. The PNP transistor inputs require such low input current that the SW-06 approaches fan-ins of CMOS input devices. These bipolar logic inputs exceed any CMOS input circuit in resistance to static voltage and radiation susceptability. No damage will occur to the SW-06 if logic high voltages are present when the SW-06 power supplies are OFF. When the V+ and V− supplies are OFF, the logic inputs present a reverse bias diode loading to active logic inputs. Input logic thresholds are independent of V+ and V− supplies making single V+ supply operation possible by simply connecting GND and V− together to the logic ground supply.

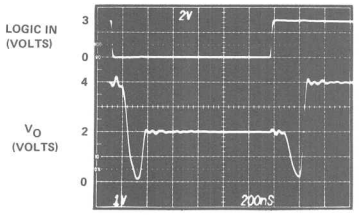
ANALOG VOLTAGE AND CURRENT

ANALOG VOLTAGE

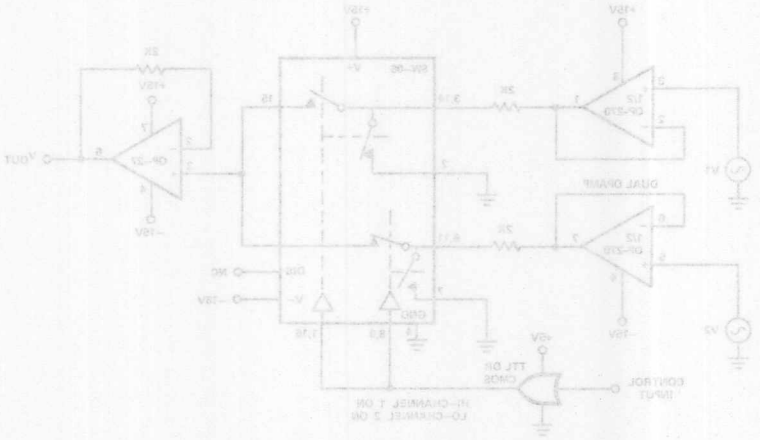
These switches have constant ON resistance for analog voltages from the negative power supply (V−) to within 4 volts of the positive power supply. This characteristic shown in the plots results in good total harmonic distortion, especially when compared to CMOS analog switches that have a 20 to 30 percent variation in ON resistance versus analog voltage. Positive analog input voltages should be restricted to 4 volts less than V+ assuring the switch remains open circuit in the OFF state. No increase in switch ON resistance occurs when operating at supply voltages less than ±15 volts (see plot). Small signals have a 3dB down frequency of 70MHz (see insertion loss versus frequency plot).



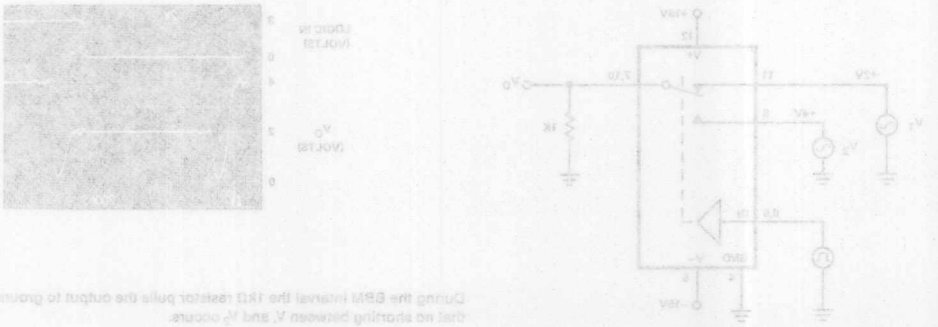
HIGH OFF ISOLATION SELECTOR SWITCH (Shunt-Series Switch)



THIS SWITCH ARRANGEMENT IMPROVES OFF ISOLATION BY 30dB



5



SINGLE POLE DOUBLE THROW SELECTOR SWITCH WITH BREAK-BEFORE-MAKE INTERVAL

During the BBM interval the 1kΩ resistor pulls the output to ground assuring that no shorting between V, and V_2 occurs.

Quad SPST JFET Analog Switches

SW-201/SW-202

FEATURES

SW-201

- **Normally "ON" for Logic 0 Input**
- **Improved Performance and Pin Compatible With DG-201, LF11201/13201, HI201, and IH201**

SW-202

- **Normally "OFF" For Logic 0 Input**
- **Improved Performance and Pin Compatible With LF11202/12202/13202 and IH202**

Both SW-201 and SW-202

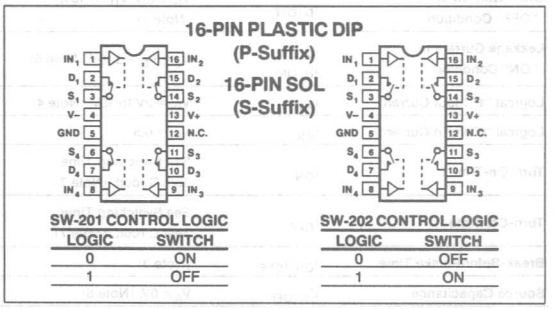
- **Highly Resistant to Static Discharge Destruction**
- **Guaranteed Break-Before-Make Switching ($t_{OFF} < t_{ON}$)**
- **Low "ON" Resistance ..... 80Ω Max**
- **Guaranteed R_{ON} Matching ..... 15% Max**
- **Low R_{ON} Variation from Analog Input Voltage 5%**
- **High Analog Current Operation ..... 10mA Min**
- **Low Leakage Currents at High Temperatures:**
  T_A = 125°C ..... 60nA Max
  T_A = 85°C ..... 30nA Max
- **Guaranteed Switching Speeds:**
  t_{ON} = 500ns Max t_{OFF} = 400ns Max
- **Digital Inputs are TTL and CMOS Compatible**
- **Dual or Single Supply Operation**
- **Available in Die Form**

ORDERING INFORMATION †

DIP PACKAGE	SWITCH CONFIGURATION NC	SWITCH CONFIGURATION NO	OPERATING TEMPERATURE RANGE
16-PIN EPOXY	SW201GP	SW202GP	XIND
16-PIN SOL	SW201GS	SW202GS	XIND

† Burn-in is available on commercial and industrial temperature range parts in CerDIP, plastic DIP, and TO-can packages.

GENERAL DESCRIPTION



The SW-201 and SW-202 each consist of four independent, single-pole, single-throw (SPST) analog switches, which may be independently digitally controlled. Each SW-201 switch is normally closed (NC), whereas each SW-202 is normally open (NO) when the corresponding digital control input is a zero. The SW-201 and SW-202 are otherwise identical.

The judicious combination of bipolar and FET devices in a single monolithic IC results in a product with performance characteristics and ruggedness that are superior to those of a similar circuit fabricated using CMOS technology.

Increased reliability is complemented by excellent electrical specifications. Potential error sources are reduced by minimizing "ON" resistance and controlling leakage currents at high temperatures. The switching FET exhibits minimal R_{ON} variation over a 20V analog signal range and with power supply voltage changes. Operation from a single positive power supply voltage is possible. With V+ = 36V, V− = 0V, the analog signal range will extend from ground to +32V.

The PNP logic inputs are TTL and CMOS compatible. Logic input currents are at micro-ampere levels which improves circuit fan in.

NOTES:

1. $V_A = 0V$, $I_D = 100\mu A$. Specified as a percentage of $R_{AVERAGE}$ where:
$$R_{AVERAGE} = \frac{R_{ON1} + R_{ON2} + R_{ON3} + R_{ON4}}{4}$$
2. Guaranteed by design.
3. Switch is guaranteed by design to provide break-before-make operation.
4. Current tested at $V_{IN} = 2V$. This is worst case condition.
5. Switch being tested ON or OFF as indicated, $V_{INH} = 2V$ or $V_{INL} = 0.8V$, per logic truth table.
6. Guaranteed by R_{ON} and leakage tests. For normal operation analog signal voltages should be restricted to less than (V+) −4V.
7. Sample tested.

APPLICATIONS INFORMATION

This analog switch employs ion-implanted JFETs in a switch configuration designed to assure break-before-make action. The turn-off time is much faster than the turn-on time to guarantee this feature over the full operating temperature and input voltage range. Fabricated with Bipolar-JFET processing rather than CMOS, special handling is not necessary to prevent damage to these switches. Because the digital inputs only require a 2V logic "1" input level, power-consuming pullup resistors are not required for TTL compatibility to insure break-before-make switching as is most often the case with CMOS switches. The digital inputs utilize PNP input transistors where input current is maximum at the logic "0" level and drops to that of a reverse-biased diode as the input voltage is raised above ≈ 1.4V.

The "ON" resistance, R_{ON}, of the analog switches is constant over the wide input voltage range of −15V to +11V with $V_{SUPPLY} = \pm 15V$. For normal operation, however, positive input voltages should be restricted to 11V (or 4V less than the positive supply). This assures that the V_{GS} of an OFF switch remains greater than its V_P, and prevents that channel from being falsely turned ON. Individual switches are "ON" without power applied.

Boldface Type: Product recommended for new design.

*New product since the publication of the most recent Databooks.

A voltage reference is used to provide an accurately known voltage which can be utilized in a circuit or system. For example, measurement systems rely on precision references in order to establish a basis for absolute measurement accuracy. Any reference inaccuracy will undermine the accuracy of the overall system. Thus, ideal references are characterized by accurately set (and traceable to recognized fundamental standards) constant output voltage, independent of temperature, load changes, input voltage variation and time.

TYPES OF REFERENCES

Some of the available IC reference circuits use the bandgap principle: the V_{BE} of any silicon transistor has a negative tempco of about 2 mV/°C, which can be extrapolated to approximately 1.2 volts at absolute zero (the *bandgap* voltage of silicon). Since identical transistors operating at constant current densities will have predictably different temperature coefficients of base emitter voltage, it is possible to arrange circuit elements so as to null out the temperature coefficients associated with the two phenomena and produce a constant voltage (usually 1.2 volts). This temperature-invariant voltage can be amplified and buffered to produce a standard voltage value, such as 2.5 V or 10.0 V. The following devices employ the bandgap architecture: AD580, AD581, AD584, AD589, AD680, REF01, REF02, REF03, REF05, REF10, and REF43.

Another popular form of reference circuit uses a selected low-drift Zener diode, followed by a buffer-amplifier as a precision-gain stage to provide a standard output voltage.

A buried-Zener design provides lower noise and drift than bandgap references. Laser trimming of thin-film resistors results in excellent accuracy and low drift versus temperature. This technique provides initial accuracy to ±1 mV and temperature drifts as low as 1.5 ppm in the AD588 (+10 V, +5 V, ±5 V tracking, −5 V and −10 V outputs) and the AD688 (±10 V tracking outputs). Similar reference designs with single voltage outputs (AD586 and AD587, +5 V and +10 V respectively) have accuracies and temperature coefficients that are nearly as good as the AD588 and AD688.

Several of the references allow the user to optionally connect a capacitor to a noise reduction pin on the IC which further reduces the noise output of the reference. In the AD586, the wideband noise (to 1 MHz) of 200 μV peak-to-peak (p–p) is reduced to 160 μV p–p by adding a 1 μF capacitor to the noise reduction point.

Many data converter ICs require a negative reference voltage, which in the past required an additional op amp to invert the output of a positive reference. The AD588 provides a ±5 V tracking output and the AD688 provides a ±10 V tracking output, while the REF-08 provides a −10 V or −10.24 V output.

Output current capability of the voltage reference must also be considered when selecting a reference. The amount of current that the reference must source, or sink, for the rest of the system affects which references are acceptable or which may need additional buffering.

Kelvin connections provide output sense and force connections, so that the actual voltage at the load is sensed and any IR drops in the leads are compensated. The AD588 and AD688 provide sense and force connections in their designs.

DEFINITION OF SPECIFICATIONS

Line Regulation
The change in output voltage due to a specified change in input voltage. It includes the effects of self-heating. Line Regulation is expressed in either percent per volt, parts-per-million per volt, or microvolts per volt change in input voltage.

Load Regulation
The change in output voltage for a specified change in load current. It includes the effects of self-heating. Load Regulation is expressed in either microvolts per milliampere, parts-per-million per milliampere, or ohms of dc output resistance.

Long-Term Stability
The change in output voltage versus time, specified in ppm/1000 hours.

Output Voltage Tolerance
The deviation from the nominal output voltage at 25°C with specified input voltage as measured by a device traceable to a recognized fundamental voltage standard.

Output Voltage Change with Temperature
The change in output voltage from the value at 25°C ambient; it is independent of variations in the other operating conditions. It may be expressed as either an error band or temperature coefficient. The error band (e.g., ±5 mV, −55°C to +125°C) is defined graphically in terms of a box (voltage vertically, temperature horizontally) whose diagonals extend from 25°C to T_{MAX} and 25°C to T_{MIN}, with a slope equal to the stated temperature coefficient. Thus, the total absolute error for a particular reference over its specified temperature range is equal to the output voltage tolerance at 25°C plus the error band.

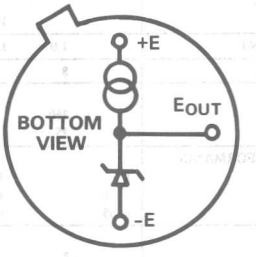
Output Temperature Coefficient
The ratio of output change with temperature variation to the specified temperature range expressed in ppm/°C.

Output Turn-On Settling Time
The time, from a cold start, for the reference output to settle within a specified error band. This definition relates only to the electrical turn-on time of the chip, and does not include thermal settling time which depends on the package, heat-sinking and load-current change.

Output Voltage Noise
The narrowband (0.1 Hz to 10 Hz) and wideband (to 1 MHz) random noise on the reference output. It may be measured in μV p–p or in nV/$\sqrt{\text{Hz}}$.

Quiescent Supply Current
The current required from the supply to operate the device with no load.

High Precision 2.5V IC Reference



AD580*

FEATURES

- Laser Trimmed to High Accuracy: 2.500V ±0.4%
- 3-Terminal Device: Voltage In/Voltage Out
- Excellent Temperature Stability: 10ppm/°C (AD580M, U)
- Excellent Long Term Stability: 250μV (25μV/Month)
- Low Quiescent Current: 1.5mA max
- Small, Hermetic IC Package: TO-52 Can
- MIL-STD-883 Compliant Versions Available

FUNCTIONAL BLOCK DIAGRAM

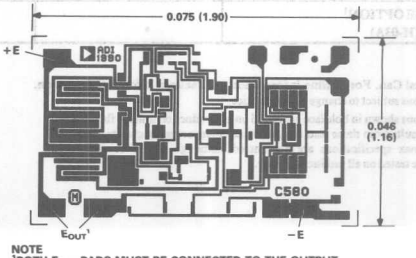
TO-52

PRODUCT DESCRIPTION

The AD580 is a three-terminal, low cost, temperature compensated, bandgap voltage reference which provides a fixed 2.5V output for inputs between 4.5V and 30V. A unique combination of advanced circuit design and laser-wafer-trimmed thin-film resistors provide the AD580 with an initial tolerance of ±0.4%, a temperature stability of better than 10ppm/°C and long-term stability of better than 250μV. In addition, the low quiescent current drain of 1.5mA max offers a clear advantage over classical zener techniques.

The AD580 is recommended as a stable reference for all 8-, 10- and 12-bit D-to-A converters that require an external reference. In addition, the wide input range of the AD580 allows operation with 5 volt logic supplies making the AD580 ideal for digital panel meter applications or whenever only a single logic power supply is available.

The AD580J, K, L and M are specified for operation over the 0 to +70°C temperature range; the AD580S, T and U are specified for operation over the extended temperature range of −55°C to +125°C.



*Protected by Patent Nos. 3,887,863; RE30, 586.

PRODUCT HIGHLIGHTS

1. Laser-trimming of the thin-film resistors minimizes the AD580 output error. For example, the AD580L output tolerance is ±10mV.
2. The three-terminal voltage in/voltage out operation of the AD580 provides regulated output voltage without any external components.
3. The AD580 provides a stable 2.5V output voltage for input voltages between 4.5V and 30V. The capability to provide a stable output voltage using a 5-volt input makes the AD580 an ideal choice for systems that contain a single logic power supply.
4. Thin film resistor technology and tightly controlled bipolar processing provide the AD580 with temperature stabilities to 10ppm/°C and long term stability better than 250μV.
5. The low quiescent current drain of the AD580 makes it ideal for CMOS and other low power applications.
6. The AD580 is available in versions compliant with MIL-STD-883. Refer to the Analog Devices Military Products Databook or current AD580/883B data sheet for detailed specifications.

AD580 CHIP DIMENSIONS AND PAD LAYOUT

Dimensions shown in inches and (mm).

NOTE
1BOTH E_{OUT} PADS MUST BE CONNECTED TO THE OUTPUT.

The AD580 is also available in chip form. Consult the factory for specifications and applications information.

THEORY OF OPERATION

The AD580 family (AD580, AD581, AD584, AD589) uses the "bandgap" concept to produce a stable, low-temperature-coefficient voltage reference suitable for high accuracy data-acquisition components and systems. The device makes use of the underlying physical nature of a silicon transistor base-emitter voltage in the forward-biased operating region. All such transistors have approximately a $-2mV/^{\circ}C$ temperature coefficient, unsuitable for use directly as a low TC reference; however, extrapolation of the temperature characteristic of any one of these devices to absolute zero (with emitter current proportional to absolute temperature) reveals that it will go to a V_{BE} of 1.205 volts at 0K, as shown in Figure 1. Thus, if a voltage could be developed with an opposing temperature coefficient to sum with V_{BE} to total 1.205 volts, a zero-TC reference would result and operation from a single, low-voltage supply would be possible. The AD580 circuit provides such a compensating voltage, V_1 in Figure 2, by driving two transistors at different current densities and amplifying the resulting V_{BE} difference (ΔV_{BE} – which now has a positive TC); the sum (V_Z) is then buffered and amplified up to 2.5 volts to provide a usable reference-voltage output. Figure 3 is the schematic diagram of the AD580.

The AD580 operates as a three-terminal reference, which means that no additional components are required for biasing or current setting. The connection diagram, Figure 4 is quite simple.

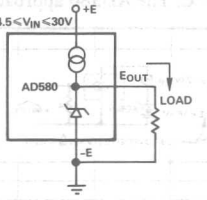

Figure 4. AD580 Connection Diagram

VOLTAGE VARIATION VS. TEMPERATURE

Some confusion exists in the area of defining and specifying reference voltage error over temperature. Historically, references are characterized using a maximum deviation per degree Centigrade; i.e., $10ppm/^{\circ}C$. However, because of the inconsistent nonlinearities in zener references (butterfly or "S" type characteristics), most manufacturers use a maximum limit error band approach to characterize their references. This technique measures the output voltage at 3 to 5 different temperatures and guarantees that the output voltage deviation will fall within the guaranteed error band at these discrete temperatures. This approach, of course, makes no mention or guarantee of performance at any other temperature within the operating temperature range of the device.

The consistent Voltage vs. Temperature performance of a typical AD580 is shown in Figure 5. Note that the characteristic is quasi-parabolic, not the possible "S" type characteristics of classical zener references. This parabolic characteristic permits a maximum output deviation specification over the device's full operating temperature range, rather than just at 3 to 5 discrete temperatures.

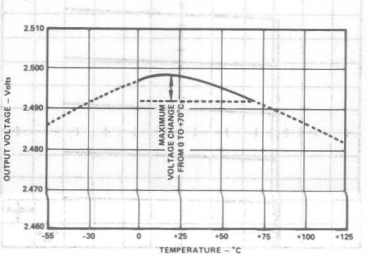

Figure 5. Typical AD580K Output Voltage vs. Temperature

6

The AD580M guarantees a maximum deviation of 1.75mV over the 0 to +70°C temperature range. This can be shown to be equivalent to 10ppm/°C average maximum; i.e. . .

$$\frac{1.75\text{mV max}}{70^\circ\text{C}} \times \frac{1}{2.5\text{V}} = 10\text{ppm}/^\circ\text{C max average}$$

The AD580 typically exhibits a variation of 1.5mV over the power supply range of 7 to 30 volts. Figure 6 is a plot of AD580 line rejection versus frequency.

NOISE PERFORMANCE

Figure 7 represents the peak-to-peak noise of the AD580 from 1Hz (3dB point) to a 3dB high end shown on the horizontal axis. Peak-to-peak noise from 1Hz to 1MHz is approximately 600μV.

THE AD580 AS A CURRENT LIMITER

The AD580 represents an excellent alternative to current limiter diodes which require factory-selection to achieve a desired current. This approach often results in temperature coefficients of 1%/°C. The AD580 approach is not limited to a specially selected factory set current limit; it can be programmed from 1 to 10mA with the insertion of a single external resistor. The approximate temperature coefficient of current limit for the AD580 used in this mode is 0.13%/°C for I_{LIM} = 1mA and 0.01%/°C for I_{LIM} = 13mA (see Figure 9). Figure 8 displays the high output impedance of the AD580 used as a current limiter for I_{LIM} = 1, 2, 3, 4, 5mA.

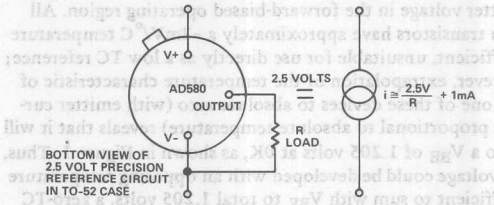

Figure 9. A Two-Component Precision Current Limiter

THE AD580 AS A LOW POWER, LOW VOLTAGE PRECISION REFERENCE FOR DATA CONVERTERS

The AD580 has a number of features that make it ideally suited for use with A/D and D/A data converters used in complex microprocessor-based systems. The calibrated 2.500 volt output minimizes user trim requirements and allows operation from a single low voltage supply. Low power consumption (1mA quiescent current) is commensurate with that of CMOS-type devices, while the low cost and small package complements the decreasing cost and size of the latest converters.

Figure 10 shows the AD580 used as a reference for the AD7542 12-bit CMOS DAC with complete microprocessor interface. The AD580 and the AD7542 are specified to operate from a single 5 volt supply; this eliminates the need to provide a +15 volt power supply for the sole purpose of operating a reference. The AD7542 includes three 4-bit data registers, a 12-bit DAC register, and address decoding logic; it may thus be interfaced directly to a 4-, 8- or 16-bit data bus. Only 8mA of quiescent current from the single +5 volt supply is required to operate the AD7542 which is packaged in a small 16-pin DIP. The AD544 output amplifier is also low power, requiring only 2.5mA quiescent current. Its laser-trimmed offset voltage preserves the ±1/2LSB linearity of the AD7542KN without user trims and it typically settles to ±1/2 LSB in less than 3μs. It will provide the 0 to –2.5 volt output swing from ±5 volt supplies.

BOTTOM VIEW

PRODUCT DESCRIPTION

The AD581 is a three-terminal, temperature compensated, monolithic band-gap voltage reference which provides a precise 10.00 volt output from an unregulated input level from 12 to 30 volts. Laser Wafer Trimming (LWT) is used to trim both the initial error at +25°C as well as the temperature coefficient, which results in high precision performance previously available only in expensive hybrids or oven-regulated modules. The 5mV initial error tolerance and 5ppm/°C guaranteed temperature coefficient of the AD581L represent the best performance combination available in a monolithic voltage reference.

The band-gap circuit design used in the AD581 offers several advantages over classical Zener breakdown diode techniques. Most important, no external components are required to achieve full accuracy and stability of significance to low power systems. In addition, total supply current to the device, including the output buffer amplifier (which can supply up to 10mA) is typically 750μA. The long-term stability of the band-gap design is equivalent or superior to selected Zener reference diodes.

The AD581 is recommended for use as a reference for 8-, 10- or 12-bit D/A converters which require an external precision reference. The device is also ideal for all types of A/D converters up to 14 bit accuracy, either successive approximation or integrating designs, and in general can offer better performance than that provided by standard self-contained references.

The AD581J, K, and L are specified for operation from 0 to +70°C; the AD581S, T, and U are specified for the −55°C to +125°C range. All grades are packaged in a hermetically-sealed three-terminal TO-5 metal can.

PRODUCT HIGHLIGHTS

1. Laser trimming of both initial accuracy and temperature coefficient results in very low errors over temperature without the use of external components. The AD581L has a maximum deviation from 10.000 volts of ±7.25mV from 0 to +70°C, while the AD581U guarantees ±15mV maximum total error without external trims from −55°C to +125°C.
2. Since the laser trimming is done on the wafer prior to separation into individual chips, the AD581 will be extremely valuable to hybrid designers for its ease of use, lack of required external trims, and inherent high performance.
3. The AD581 can also be operated in a two-terminal "Zener" mode to provide a precision negative 10 volt reference with just one external resistor to the unregulated supply. The performance in this mode is nearly equal to that of the standard three-terminal configuration.
4. Advanced circuit design using the band-gap concept allows the AD581 to give full performance with an unregulated input voltage down to 13 volts. With an external resistor, the device will operate with a supply as low as 11.4 volts.
5. The AD581 is available in versions compliant with MIL-STD-883. Refer to the Analog Devices Military Products Databook or current AD581/883B data sheet for detailed specifications.

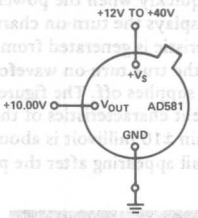
APPLYING THE AD581

The AD581 is easy to use in virtually all precision reference applications. The three terminals are simply primary supply, ground, and output, with the case grounded. No external components are required even for high precision applications; the degree of desired absolute accuracy is achieved simply by selecting the required device grade. The AD581 requires less than 1mA quiescent current from an operating supply range of 12 to 30 volts.



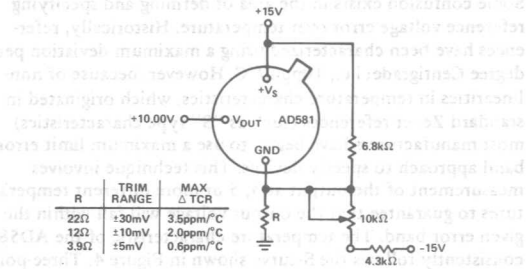


Figure 1. AD581 Pin Configuration (Top View)

An external fine trim may be desired to set the output level to exactly 10.000 volts within less than a millivolt (calibrated to a main system reference). System calibration may also require a reference slightly different from 10.00 volts. In either case, the optional trim circuit shown in Figure 2 can offset the output by up to ±30 millivolts (with the 22Ω resistor), if needed, with minimal effect on other device characteristics.

R	TRIM RANGE	MAX Δ TCR
22Ω	±30mV	3.5ppm/°C
12Ω	±10mV	2.0ppm/°C
3.9Ω	±5mV	0.6ppm/°C

Figure 2. Optional Fine Trim Configuration

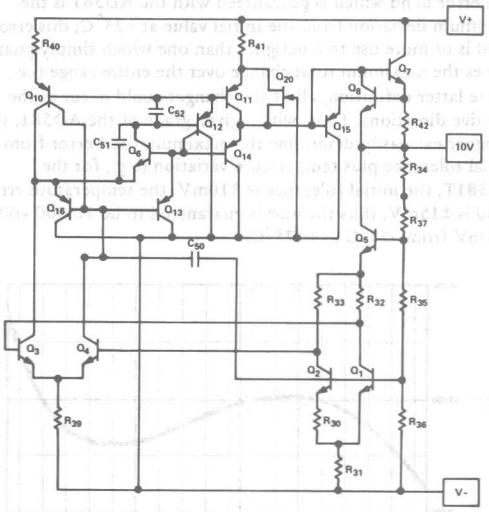

Figure 3. Simplified Schematic

reference voltage error over temperature. Historically, references have been characterized using a maximum deviation per degree Centigrade; i.e., 10ppm/°C. However, because of nonlinearities in temperature characteristics, which originated in standard Zener references (such as "S" type characteristics) most manufacturers have begun to use a maximum limit error band approach to specify devices. This technique involves measurement of the output at 3, 5 or more different temperatures to guarantee that the output voltage will fall within the given error band. The temperature characteristic of the AD581 consistently follows the S-curve shown in Figure 4. Three-point measurement of each device guarantees the error band over the specified temperature range.

The error band which is guaranteed with the AD581 is the maximum deviation from the initial value at +25°C; this error band is of more use to a designer than one which simply guarantees the maximum total change over the entire range (i.e., in the latter definition, all of the changes could occur in the positive direction). Thus, with a given grade of the AD581, the designer can easily determine the maximum total error from initial tolerance plus temperature variation (e.g., for the AD581T, the initial tolerance is ±10mV, the temperature error band is ±15mV, thus the unit is guaranteed to be 10.000 volts ±25mV from -55°C to +125°C).

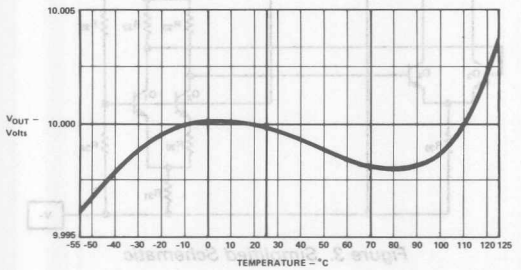

Figure 4. Typical Temperature Characteristic

OUTPUT CURRENT CHARACTERISTICS

The AD581 has the capability to either source or sink current and provide good load regulation in either direction, although it has better characteristics in the source mode (positive current into the load). The circuit is protected for shorts to either positive supply or ground. The output voltage vs. output current is displayed as negative current in the figure; sink current is positive. Note that the short circuit current (i.e., zero volts output) is about 28mA; when shorted to +15 volts, the sink current goes to about 20mA.

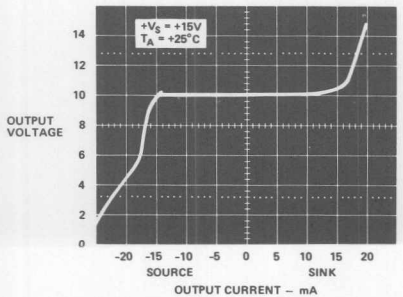

Figure 5. AD581 Output Voltage vs. Sink and Source Current

DYNAMIC PERFORMANCE

Many low power instrument manufacturers are becoming increasingly concerned with the turn-on characteristics of the components being used in their systems. Fast turn-on components often enable the end user to keep power off when not needed, and yet respond quickly when the power is turned on for operation. Figure 6 displays the turn-on characteristic of the AD581. This characteristic is generated from cold-start operation and represents the true turn-on waveform after an extended period with the supplies off. The figure shows both the coarse and fine transient characteristics of the device; the total settling time to within ±10 millivolt is about 180μs, and there is no long thermal tail appearing after the point.

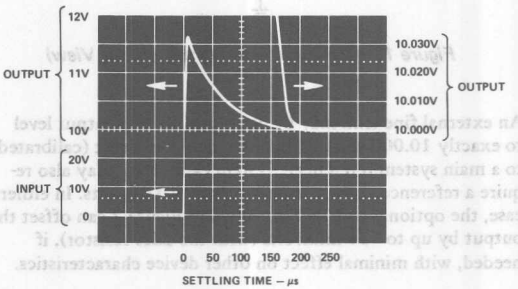

Figure 6. Output Settling Characteristic

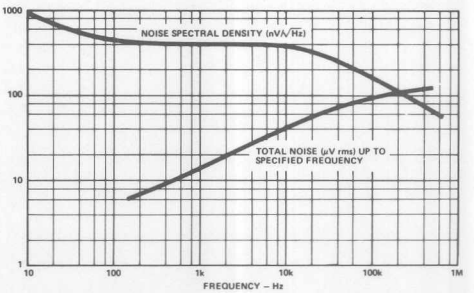

Figure 7. Spectral Noise Density and Total rms Noise vs. Frequency

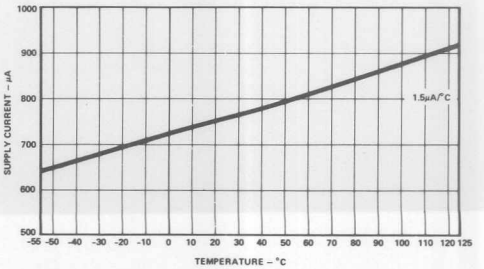

Figure 8. Quiescent Current vs. Temperature

darlington pnp devices to provide much greater output current capability. The circuit shown in Figure 9 delivers a precision 10 volt output with up to 4 amperes supplied to the load. The 0.1μF capacitor is required only if the load has a significant capacitive component. If the load is purely resistive, improved high frequency supply rejection results from removing the capacitor.

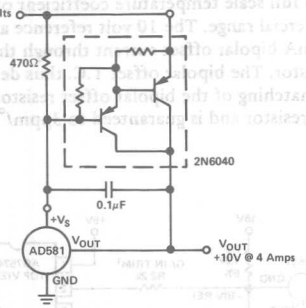

Figure 9. High Current Precision Supply

CONNECTION FOR REDUCED PRIMARY SUPPLY

While line regulation is specified down to 13 volts, the typical AD581 will work as specified down to 12 volts or below. The current sink capability allows even lower supply voltage capability such as operation from 12V ±5% as shown in Figure 10. The 560Ω resistor reduces the current supplied by the AD581 to a manageable level at full 5mA load. Note that the other bandgap references, without current sink capability, may be damaged by use in this circuit configuration.

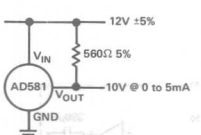

Figure 10. 12-Volt Supply Connection

THE AD581 AS A CURRENT LIMITER

The AD581 represents an alternative to current limiter diodes which require factory selection to achieve a desired current. This approach often results in temperature coefficients of 1%/°C. The AD581 approach is not limited to a defined set current limit; it can be programmed from 0.75 to 5mA with the insertion of a single external resistor. Of course, the minimum voltage required to drive the connection is 13 volts. The AD580, which is a 2.5 volt reference, can be used in this type of circuit with compliance voltage down to 4.5 volts.

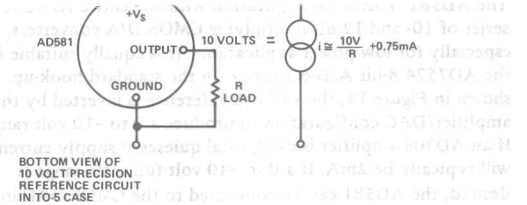

Figure 11. A Two-Component Precision Current Limiter

NEGATIVE 10-VOLT REFERENCE

The AD581 can also be used in a two-terminal "Zener" mode to provide a precision −10.00 volt reference. As shown in Figure 13, the V_{IN} and V_{OUT} terminals are connected together to the high supply (in this case, ground). The ground pin is connected through a resistor to the negative supply. The output is now taken from the ground pin instead of V_{OUT}. With 1mA flowing through the AD581 in this mode, a typical unit will show a 2mV increase in output level over that produced in the three-terminal mode. Note also that the effective output impedance in this connection increases from 0.2Ω typical to 2 ohms. It is essential to arrange the output load and the supply resistor, R_S, so that the net current through the AD581 is always between 1 and 5mA. For operation to +125°C, the net current should be between 2 and 5mA. The temperature characteristics and long-term stability of the device will be essentially the same as that of a unit used in the standard three-terminal mode.

The AD581 can also be used in a two-terminal mode to develop a positive reference. V_{IN} and V_{OUT} are tied together and to the positive supply through an appropriate supply resistor. The performance characteristics will be similar to those of the negative two-terminal connection. The only advantage of this connection over the standard three-terminal connection is that a lower primary supply can be used, as low as 10.5 volts. This type of operation will require considerable attention to load and primary supply regulation to be sure the AD581 always remains within its regulating range of 1 to 5mA (2 to 5mA for operation beyond +85°C).

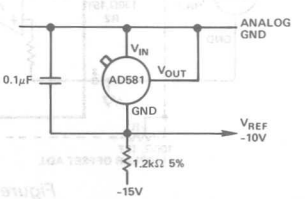

Figure 12. Two-Terminal −10 Volt Reference

6

10 VOLT REFERENCE WITH MULTIPLYING CMOS D/A OR A/D CONVERTERS

The AD581 is ideal for application with the entire AD7533 series of 10- and 12-bit multiplying CMOS D/A converters, especially for low power applications. It is equally suitable for the AD7574 8-bit A/D converter. In the standard hook-up, as shown in Figure 14, the +10 volt reference is inverted by the amplifier/DAC configuration to produce a 0 to −10 volt range. If an AD308 amplifier is used, total quiescent supply current will typically be 2mA. If a 0 to +10 volt full scale range is desired, the AD581 can be connected to the CMOS DAC in its −10 volt "Zener" mode, as shown in Figure 12 (the $-10V_{REF}$ output is connected directly to the $V_{REF\ IN}$ of the CMOS DAC). The AD581 will normally be used in the −10 volt mode with the AD7574 to give a 0 to +10 volt ADC range. This is shown in Figure 14. Bipolar output applications and other operating details can be found in the data sheets for the CMOS products.

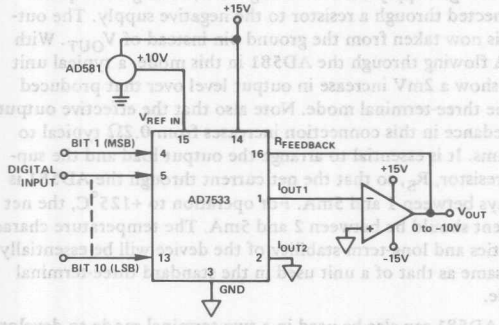

Figure 13. Low Power 10-Bit CMOS DAC Application

PRECISION 12-BIT D/A CONVERTER REFERENCE

The AD562, like most D/A converters, is designed to operate with a +10 volt reference element. In the AD562, this 10 volt reference voltage is converted into a reference current of approximately 0.5mA via the internal 19.95kΩ resistor (in series with the external 100Ω trimmer). The gain temperature coefficient of the AD562 is primarily governed by the temperature tracking of the 19.95kΩ resistor and the 5k/10k span resistors; this gain T.C. is guaranteed to 3ppm/°C. Thus, using the AD581L (at 5ppm/°C) as the 10 volt reference guarantees a maximum full scale temperature coefficient of 8ppm/°C over the commercial range. The 10 volt reference also supplies the normal 1mA bipolar offset current through the 9.95k bipolar offset resistor. The bipolar offset T.C. thus depends only on the T.C. matching of the bipolar offset resistor to the input reference resistor and is guaranteed to 3ppm/°C.

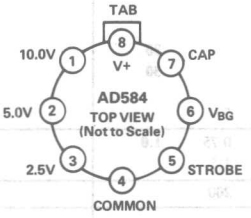
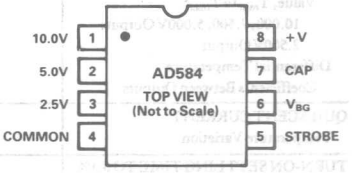
Pin Programmable Precision Voltage Reference



AD584*

FEATURES



- Four Programmable Output Voltages:
  - 10.000V, 7.500V, 5.000V, 2.500V
- Laser-Trimmed to High Accuracies
- No External Components Required
- Trimmed Temperature Coefficient:
  - 5ppm/°C max, 0 to +70°C (AD584L)
  - 15ppm/°C max, −55°C to +125°C (AD584T)
- Zero Output Strobe Terminal Provided
- Two Terminal Negative Reference Capability (5V & Above)
- Output Sources or Sinks Current
- Low Quiescent Current: 1.0mA max
- 10mA Current Output Capability
- MIL-STD-883 Compliant Versions Available

PIN CONFIGURATIONS

8-Pin TO-99

8-Pin DIP

PRODUCT DESCRIPTION

The AD584 is an eight-terminal precision voltage reference offering pin-programmable selection of four popular output voltages: 10.000V, 7.500V, 5.000V and 2.500V. Other output voltages, above, below or between the four standard outputs, are available by the addition of external resistors. Input voltage may vary between 4.5 and 30 volts.

Laser Wafer Trimming (LWT) is used to adjust the pin-programmable output levels and temperature coefficients, resulting in the most flexible high precision voltage reference available in monolithic form.

In addition to the programmable output voltages, the AD584 offers a unique strobe terminal which permits the device to be turned on or off. When the AD584 is used as a power supply reference, the supply can be switched off with a single, low-power signal. In the "off" state the current drain by the AD584 is reduced to about 100μA. In the "on" state the total supply current is typically 750μA including the output buffer amplifier.

The AD584 is recommended for use as a reference for 8-, 10- or 12-bit D/A converters which require an external precision reference. The device is also ideal for all types of A/D converters of up to 14 bit accuracy, either successive approximation or integrating designs, and in general can offer better performance than that provided by standard self-contained references.

The AD584J, K and L are specified for operation from 0 to +70°C; the AD584S and T are specified for the -55°C to +125°C range. All grades are packaged in a hermetically sealed eight-terminal TO-99 metal can; the AD584J and K are also available in an 8-pin plastic DIP.

*Protected by U.S. Patent No. 3,887,863; RE 30, 586

PRODUCT HIGHLIGHTS

1. The flexibility of the AD584 eliminates the need to design-in and inventory several different voltage references. Furthermore one AD584 can serve as several references simultaneously when buffered properly.
2. Laser trimming of both initial accuracy and temperature coefficient results in very low errors over temperature without the use of external components. The AD584LH has a maximum deviation from 10.000 volts of ±7.25mV from 0 to +70°C.
3. The AD584 can be operated in a two-terminal "Zener" mode at 5 volts output and above. By connecting the input and the output, the AD584 can be used in this "Zener" configuration as a negative reference.
4. The output of the AD584 is configured to sink or source currents. This means that small reverse currents can be tolerated in circuits using the AD584 without damage to the reference and without disturbing the output voltage (10V, 7.5V and 5V outputs).
5. The AD584 is available in versions compliant with MIL-STD-883. Refer to the Analog Devices Military Products Databook or current AD584/883B data sheet for detailed specifications.

Applying the AD584

APPLYING THE AD584

With power applied to pins 8 and 4 and all other pins open the AD584 will produce a buffered nominal 10.0V output between pins 1 and 4 (see Figure 1). The stabilized output voltage may be reduced to 7.5V, 5.0V or 2.5V by connecting the programming pins as follows:

OUTPUT VOLTAGE	PIN PROGRAMMING
7.5V	Join the 2.5V and 5.0V pins (2) and (3).
5.0V	Connect the 5.0V pin (2) to the output pin (1).
2.5V	Connect the 2.5V pin (3) to the output pin (1).

The options shown above are available without the use of any additional components. Multiple outputs using only one AD584, are also possible by simply buffering each voltage programming pin with a unity-gain noninverting op amp.

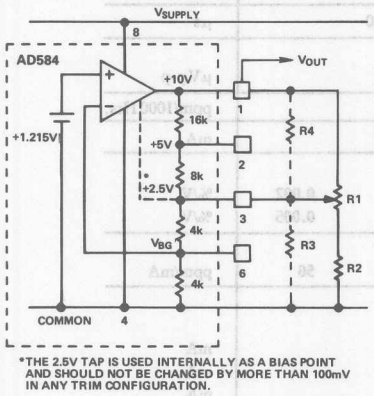

Figure 1. Variable Output Options

The AD584 can also be programmed over a wide range of output voltages, including voltages greater than 10V, by the addition of one or more external resistors. Figure 1 illustrates the general adjustment procedure, with approximate values given for the internal resistors of the AD584. The AD584 may be modeled as an op amp with a noninverting feedback connection, driven by a high stability 1.215 volt bandgap reference (see Figure 3 for schematic).

When the feedback ratio is adjusted with external resistors, the output amplifier can be made to multiply the reference voltage by almost any convenient amount, making popular outputs of 10.24V, 5.12V, 2.56V or 6.3V easy to obtain. The most general adjustment (which gives the greatest range and poorest resolution) uses R1 and R2 alone (see Figure 1). As R1 is adjusted to its upper limit the 2.5V pin 3 will be connected to the output, which will reduce to 2.5V. As R1 is adjusted to its lower limit, the output voltage will rise to a value limited by R2. For example, if R2 is about 6kΩ, the upper limit of the output range will be about 20V even for large values of R1. R2 should not be omitted; its value should be chosen to limit the output to a value which can be tolerated by the load circuits. If R2 is zero, adjusting R1 to its lower limit will result in a loss of control over the output voltage. If precision voltages are required to be set at levels other than the standard outputs, the 20% absolute tolerance in the internal resistor ladder must be accounted for.

Alternatively, the output voltage can be raised by loading the 2.5V tap with R3 alone. The output voltage can be lowered by connecting R4 alone. Either of these resistors can be a fixed resistor selected by test or an adjustable resistor. In all cases the resistors should have a low temperature coefficient to match the AD584 internal resistors, which have a negative T.C. less than 60ppm/°C. If both R3 and R4 are used, these resistors should have matched temperature coefficients.

When only small adjustments or trims are required, the circuit of Figure 2 offers better resolution over a limited trim range. The circuit can be programmed to 5.0V, 7.5V or 10V and adjusted by means of R1 over a range of about ±200mV. To trim the 2.5V output option, R2 (Figure 2) can be reconnected to the bandgap reference (pin 6). In this configuration, the adjustment should be limited to ±100mV in order to avoid affecting the performance of the AD584.

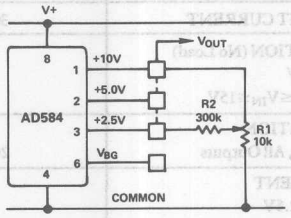

Figure 2. Output Trimming

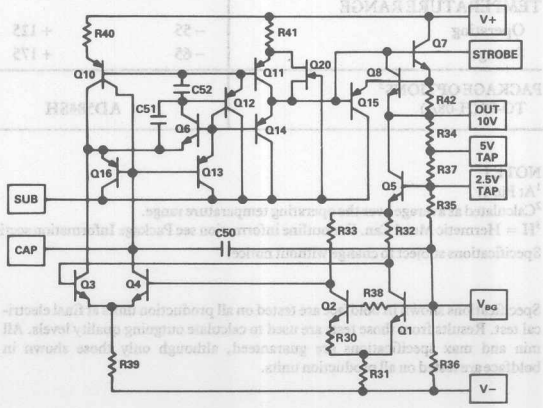

Figure 3. Schematic Diagram

PERFORMANCE OVER TEMPERATURE

Each AD584 is tested at three temperatures over the -55°C to +125°C range to ensure that each device falls within the Maximum Error Band (see Figure 4) specified for a particular grade (i.e., S and T grades); three-point measurement also guarantees performance within the error band from 0 to +70°C (i.e., J, K, or L grades). The error band guaranteed for the AD584 is the maximum deviation from the initial value at +25°C. Thus, given the grade of the AD584, the designer can easily determine the maximum total error from initial tolerance plus temperature variation. For example, for the AD584T, the initial tolerance is ±10mV and the error band is ±15mV. Hence, the unit is guaranteed to be 10.000 volts ±25mV from -55°C to +125°C.

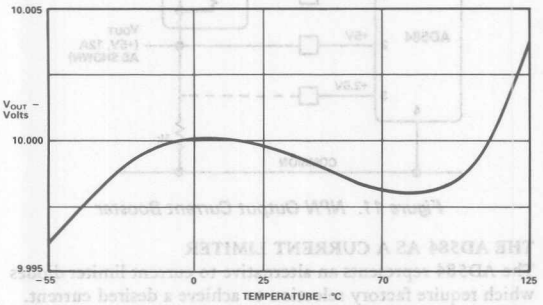

Figure 4. Typical Temperature Characteristic

OUTPUT CURRENT CHARACTERISTICS

The AD584 has the capability to either source or sink current and provide good load regulation in either direction, although it has better characteristics in the source mode (positive current into the load). The circuit is protected for shorts to either positive supply or ground. The output voltage vs. output current characteristics of the device is shown in Figure 5. Source current is displayed as negative current in the figure; sink current is positive. Note that the short circuit current (i.e., zero volts output) is about 28mA; when shorted to +15 volts, the sink current goes to about 20mA.

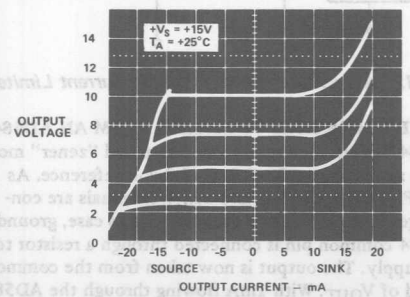

Figure 5. AD584 Output Voltage vs. Sink and Source Current

DYNAMIC PERFORMANCE

Many low power instrument manufacturers are becoming increasingly concerned with the turn-on characteristics of the components being used in their systems. Fast turn-on components often enable the end user to keep power off when not needed, and yet respond quickly when the power is turned on for operation. Figure 6 displays the turn-on characteristic of the AD584. Figure 6a is generated from cold-start operation and represents the true turn-on waveform after an extended period with the supplies off. The figure shows both the coarse and fine transient characteristics of the device; the total settling time to within ±10 millivolts is about 180μs, and there is no long thermal tail appearing after the point.

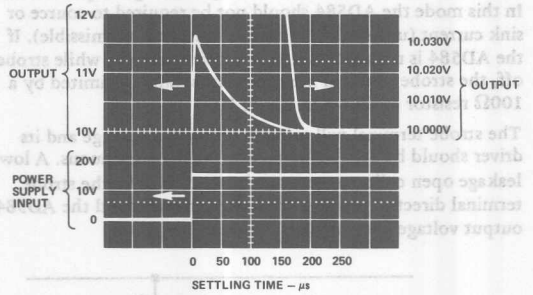

Figure 6. Output Settling Characteristic

NOISE FILTERING

The bandwidth of the output amplifier in the AD584 can be reduced to filter the output noise. A capacitor ranging between 0.01μF and 0.1μF connected between the Cap and V_{BG} terminals will further reduce the wideband and feedthrough noise in the output of the AD584, as shown in Figure 8. However, this will tend to increase the turn-on settling time of the device so ample warm-up time should be allowed.

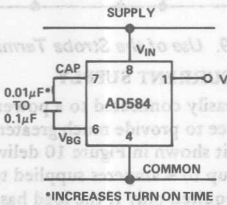

Figure 7. Additional Noise Filtering with an External Capacitor

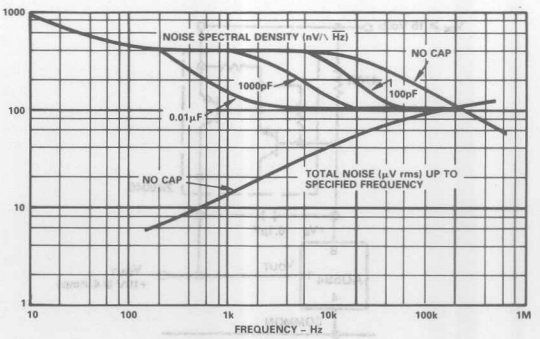

Figure 8. Spectral Noise Density and Total rms Noise vs. Frequency

AD584—Applications

USING THE STROBE TERMINAL

The AD584 has a strobe input which can be used to zero the output. This unique feature permits a variety of new applications in signal and power conditioning circuits.

Figure 9 illustrates the strobe connection. A simple NPN switch can be used to translate a TTL logic signal into a strobe of the output. The AD584 operates normally when there is no current drawn from pin 5. Bringing this terminal low, to less than 200mV, will allow the output voltage to go to zero. In this mode the AD584 should not be required to source or sink current (unless a 0.7V residual output is permissible). If the AD584 is required to sink a transient current while strobed off, the strobe terminal input current should be limited by a 100Ω resistor as shown in Figure 9.

The strobe terminal will tolerate up to 5μA leakage and its driver should be capable of sinking 500μA continuous. A low leakage open collector gate can be used to drive the strobe terminal directly, provided the gate can withstand the AD584 output voltage plus one volt.

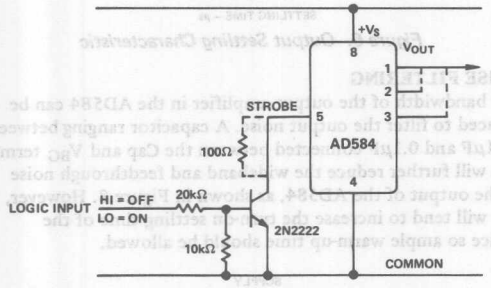

Figure 9. Use of the Strobe Terminal

PRECISION HIGH CURRENT SUPPLY

The AD584 can be easily connected to a power PNP or power Darlington PNP device to provide much greater output current capability. The circuit shown in Figure 10 delivers a precision 10 volt output with up to 4 amperes supplied to the load. The 0.1μF capacitor is required only if the load has a significant capacitive component. If the load is purely resistive, improved high frequency supply rejection results from removing the capacitor.

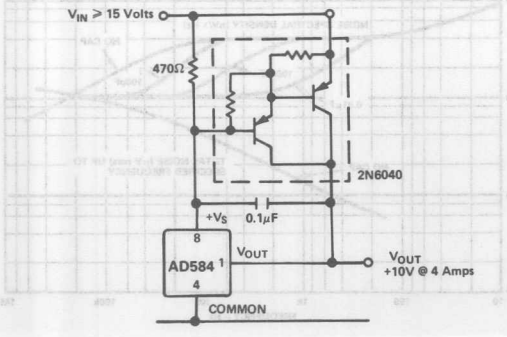

Figure 10. High Current Precision Supply

The AD584 can also use an NPN or Darlington NPN transistor to boost its output current. Simply connect the 10V output terminal of the AD584 to the base of the NPN booster and take the output from the booster emitter as shown in Figure 11. The 5.0V or 2.5V pin must connect to the actual output in this configuration. Variable or adjustable outputs (as shown in Figures 1 and 2) may be combined with +5.0V connection to obtain outputs above +5.0V.

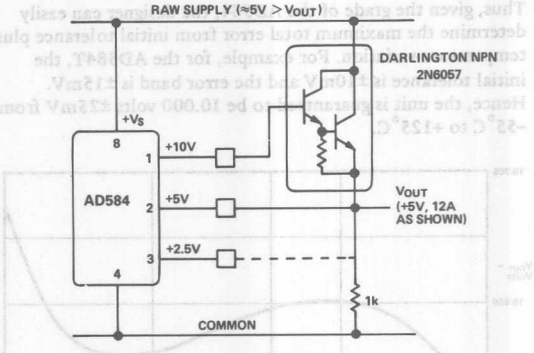

Figure 11. NPN Output Current Booster

THE AD584 AS A CURRENT LIMITER

The AD584 represents an alternative to current limiter diodes which require factory selection to achieve a desired current. Use of current limiting diodes often results in temperature coefficients of 1%/°C. Use of the AD584 in this mode is not limited to a set current limit; it can be programmed from 0.75 to 5mA with the insertion of a single external resistor (see Figure 12). Of course, the minimum voltage required to drive the connection is 5 volts.

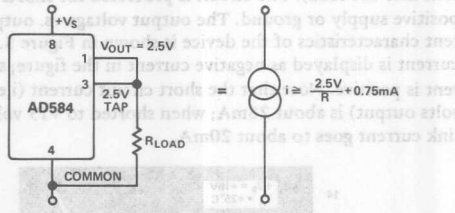

Figure 12. A Two-Component Precision Current Limiter

NEGATIVE REFERENCE VOLTAGES FROM AN AD584

The AD584 can also be used in a two-terminal "zener" mode to provide a precision –10, –7.5 or –5.0 volt reference. As shown in Figure 13, the V_{IN} and V_{OUT} terminals are connected together to the positive supply (in this case, ground). The AD584 common pin is connected through a resistor to the negative supply. The output is now taken from the common pin instead of V_{OUT}. With 1mA flowing through the AD584 in this mode, a typical unit will show a 2mV increase in output level over that produced in the three-terminal mode. Note also that the effective output impedance in this connection increases from 0.2Ω typical to 2Ω. It is essential to arrange the output load and the supply resistor, R_S, so that the net current through the AD584 is always between 1 and 5mA (between 2 and 5mA for operation beyond +85°C). The temperature characteristics and long-term stability of the

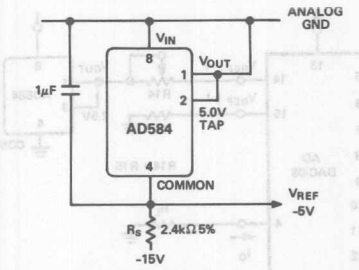

Figure 13. Two-Terminal -5 Volt Reference

device will be essentially the same as that of a unit used in the standard three-terminal mode.

The AD584 can also be used in a two-terminal mode to develop a positive reference. V_{IN} and V_{OUT} are tied together and to the positive supply through an appropriate supply resistor. The performance characteristics will be similar to those of the negative two-terminal connection. The only advantage of this connection over the standard three-terminal connection is that a lower primary supply can be used, as low as 0.5 volts above the desired output voltage. This type of operation will require considerable attention to load and primary supply regulation to be sure the AD584 always remains within its regulating range of 1 to 5mA (2 to 5mA for operation beyond 85°C).

10 VOLT REFERENCE WITH MULTIPLYING CMOS D/A OR A/D CONVERTERS

The AD584 is ideal for application with the entire AD7520 series of 10- and 12-bit multiplying CMOS D/A converters, especially for low power applications. It is equally suitable for the AD7574 8-bit A/D converter. In the standard hook-up as shown in Figure 14, the standard output voltages are inverted by the amplifier/DAC configuration to produce converted voltage ranges. For example, a +10V reference produces a 0 to -10V range. If an AD308 amplifier is used, total quiescent supply current will typically be 2mA. The AD584 will normally be used in the -10 volt mode with the AD7574 to give a 0 to +10 volt ADC range. This is shown in Figure 16. Bipolar output applications and other operating details can be found in the data sheets for the CMOS products.

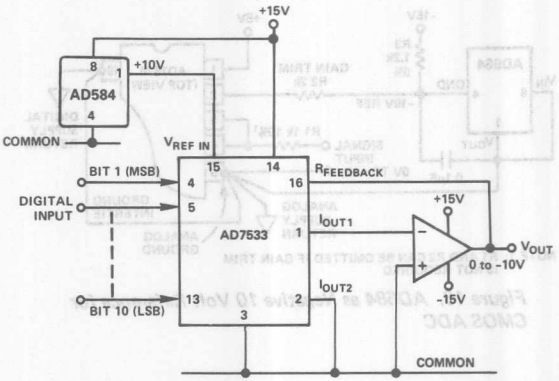

Figure 14. Low Power 10-Bit CMOS DAC Application

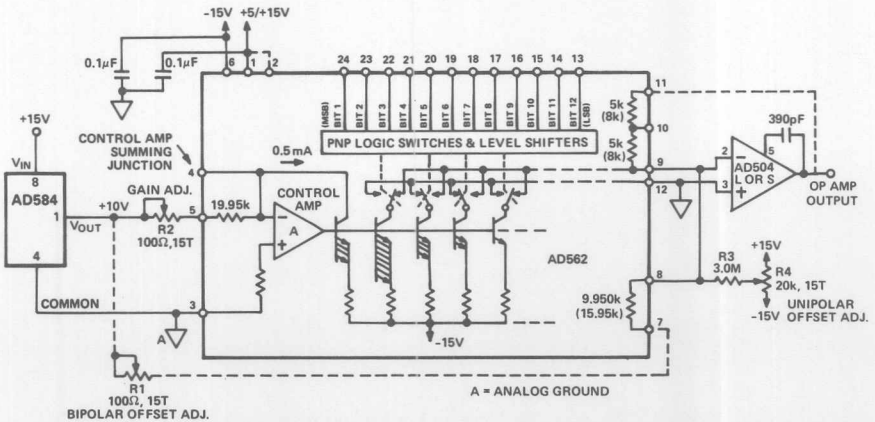
PRECISION D/A CONVERTER REFERENCE

The AD562, like many D/A converters, is designed to operate with a +10 volt reference element (Figure 15). In the AD562, this 10 volt reference voltage is converted into a reference current of approximately 0.5mA via the internal 19.95kΩ resistor (in series with the external 100Ω trimmer). The gain temperature coefficient of the AD562 is primarily governed by the temperature tracking of the 19.95kΩ resistor and the 5k/10k



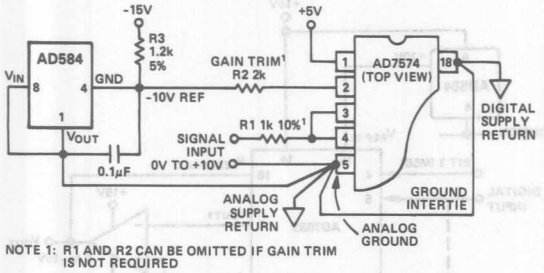


Figure 15. Precision 12-Bit D/A Converter

using the AD584L (at 5ppm/˚C) as the 10 volt reference guarantees a maximum full scale temperature coefficient of 8ppm/°C over the commercial range. The 10 volt reference also supplies the normal 1mA bipolar offset current through the 9.95k bipolar offset resistor. The bipolar offset T.C. thus depends only on the T.C. matching of the bipolar offset resistor to the input reference resistor and is guaranteed to 3ppm/°C. Figure 17 demonstrates the flexibility of the AD584 applied to another popular D/A configuration.

PRODUCT DESCRIPTION

The AD586 represents a major advance in the state-of-the-art in monolithic voltage references. Using a proprietary ion-implanted buried Zener diode and laser wafer trimming of high stability thin-film resistors, the AD586 provides outstanding performance at low cost.

The AD586 offers much higher performance than most other 5V references. Because the AD586 uses an industry standard pinout, many systems can be upgraded instantly with the AD586. The buried Zener approach to reference design provides lower noise and drift than bandgap voltage references. The AD586 offers a noise reduction pin which can be used to further reduce the noise level generated by the buried Zener.

The AD586 is recommended for use as a reference for 8-, 10-, 12-, 14- or 16-bit D/A converters which require an external precision reference. The device is also ideal for successive approximation or integrating A/D converters with up to 14 bits of accuracy and, in general, can offer better performance than the standard on-chip references.

The AD586J, K, L and M are specified for operation from 0 to +70°C, and the AD586S and T are specified for −55°C to +125°C operation. All grades, except for the AD586M, are packaged in an 8-pin cerdip package. The AD586J, K, L and M are available in an 8-pin plastic package. The AD586J and the AD586K are also available in an 8-pin plastic surface mount small outline (SO) package.

PRODUCT HIGHLIGHTS

1. Laser trimming of both initial accuracy and temperature coefficients results in very low errors over temperature without the use of external components. The AD586M has a maximum deviation from 5.000V of ±2.45mV between 0 and +70°C, and the AD586T guarantees ±7.5mV maximum total error between −55°C and +125°C.
2. For applications requiring higher precision, an optional fine-trim connection is provided.
3. Any system using an industry standard pinout reference can be upgraded instantly with the AD586.
4. Output noise of the AD586 is very low, typically 4μV p-p. A noise reduction pin is provided for additional noise filtering using an external capacitor.
5. The AD586 is available in versions compliant with MIL-STD-883. Refer to the Analog Devices Military Products Databook or current AD586/883B data sheet for detailed specifications.

Short-Circuit Current-to-Ground			60	mA

DIE LAYOUT

Die Size: 0.96 × 0.061 inches

NOTES

[1]Both V_{OUT} pads should be connected to the output.

Die Thickness: The standard thickness of Analog Devices Bipolar dice is 24 mils ± 2 mils.

Die Dimensions: The dimensions given have a tolerance of ± 2 mils.

Backing: The standard backside surface is silicon (not plated). Analog Devices does not recommend gold-backed dice for most applications.

Edges: A diamond saw is used to separate wafers into dice thus providing perpendicular edges half-way through the die. In contrast to scribed dice, this technique provides a more uniform die shape and size. The perpendicular edges facilitate handling (such as tweezer pick-up) while the uniform shape and size simplifies substrate design and die attach.

Top Surface: The standard top surface of the die is covered by a layer of glassivation. All areas are covered except bonding pads and scribe lines.

Surface Metalization: The metalization to Analog Devices bipolar dice is aluminum. Minimum thickness is 10,000Å.

Bonding Pads: All bonding pads have a minimum size of 4 mils by 4 mils. The passivation windows have 3.5 mils by 3.5 mils minimum.

6

an amplifier to buffer the output and several high stability thin-film resistors as shown in the block diagram in Figure 1. This design results in a high precision monolithic 5V output reference with initial offset of 2.5mV or less. The temperature compensation circuitry provides the device with a temperature coefficient of under 5 ppm/°C.

Using the bias compensation resistor between the Zener output and the noninverting input to the amplifier, a capacitor can be added at the NOISE REDUCTION pin (Pin 8) to form a low pass filter and reduce the noise contribution of the Zener to the circuit.

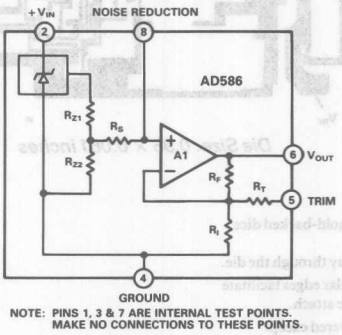

Figure 1. AD586 Functional Block Diagram

APPLYING THE AD586

The AD586 is simple to use in virtually all precision reference applications. When power is applied to Pin 2 and Pin 4 is grounded, Pin 6 provides a 5V output. No external components are required; the degree of desired absolute accuracy is achieved simply by selecting the required device grade. The AD586 requires less than 3mA quiescent current from an operating supply of +12V or +15V.

An external fine trim may be desired to set the output level to exactly 5.000V (calibrated to a main system reference). System calibration may also require a reference voltage that is slightly different from 5.000V, for example, 5.12V for binary applications. In either case, the optional trim circuit shown in Figure 2 can offset the output by as much as 300mV, if desired, with minimal effect on other device characteristics.

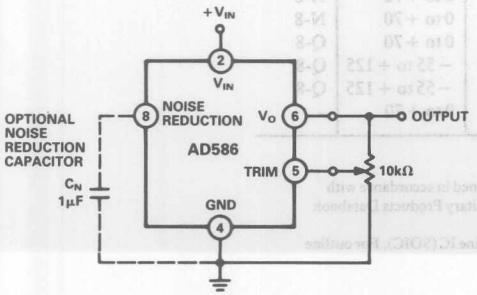

Figure 2. Optional Fine Trim Configuration

p-p over the 0.1Hz to 10Hz band. Noise in a 1MHz bandwidth is approximately 200μV p-p. The dominant source of this noise is the buried Zener which contributes approximately 100nV/$\sqrt{\text{Hz}}$. In comparison, the op amp's contribution is negligible. Figure 3 shows the 0.1Hz to 10Hz noise of a typical AD586. The noise measurement is made with a bandpass filter made of a 1-pole high-pass filter with a corner frequency at 0.1Hz and a 2-pole low-pass filter with a corner frequency at 12.6Hz to create a filter with a 9.922Hz bandwidth.

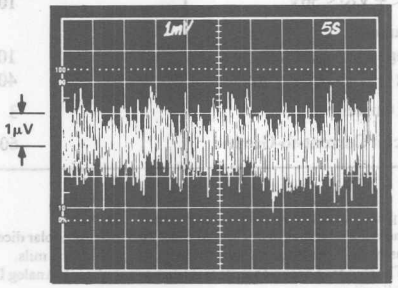

Figure 3. 0.1Hz to 10Hz Noise

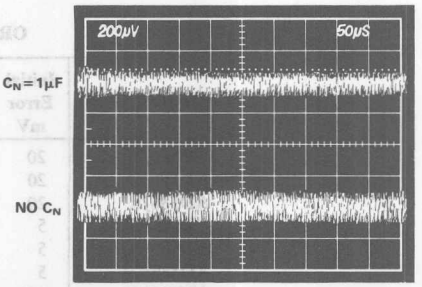
If further noise reduction is desired, an external capacitor may be added between the NOISE REDUCTION pin and ground as shown in Figure 2. This capacitor, combined with the 4kΩ R_S and the Zener resistances form a low-pass filter on the output of the Zener cell. A 1μF capacitor will have a 3dB point at 12Hz, and it will reduce the high-frequency (to 1MHz) noise to about 160μV p-p. Figure 4 shows the 1MHz noise of a typical AD586 both with and without a 1μF capacitor.



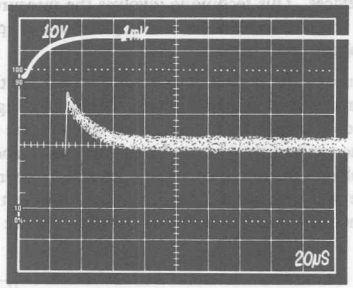


Figure 4. Effect of 1μF Noise Reduction Capacitor on Broadband Noise

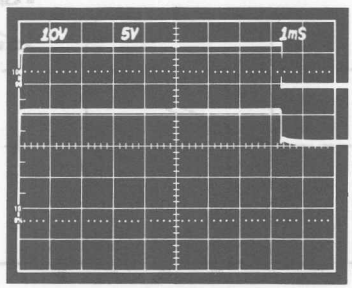
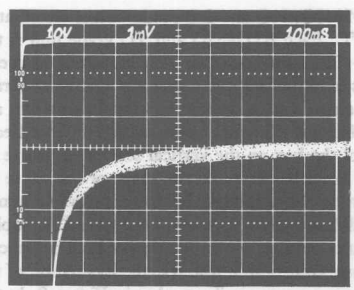


TURN-ON TIME

Upon application of power (cold start), the time required for the output voltage to reach its final value within a specified error band is defined as the turn-on settling time. Two components normally associated with this are: the time for the active circuits to settle, and the time for the thermal gradients on the chip to stabilize. Figure 5 shows the turn-on characteristics of the AD586. It shows the settling to be about 60μsec to 0.01%. Note the absence of any thermal tails when the horizontal scale is expanded to 1ms/cm in Figure 5b.



capacitor is used. When present, this capacitor acts as an additional load to the internal Zener diode's current source, resulting in a somewhat longer turn-on time. In the case of a 1μF capacitor, the initial turn-on time is approximately 400ms to 0.01% (see Figure 5c).

a. Electrical Turn-On

b. Extended Time Scale

c. Turn-On with 1μF C_N

Figure 5. Turn-On Characteristics

The output buffer amplifier is designed to provide the AD586 with static and dynamic load regulation superior to less complete references.

Many A/D and D/A converters present transient current loads to the reference, and poor reference response can degrade the converter's performance.

Figure 6 displays the characteristics of the AD586 output amplifier driving a 0 to 10mA load.

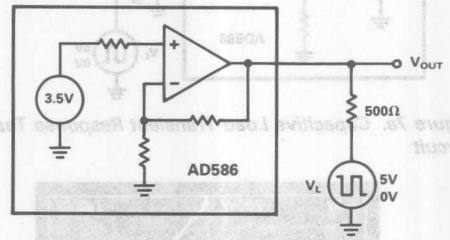


Figure 6a. Transient Load Test Circuit

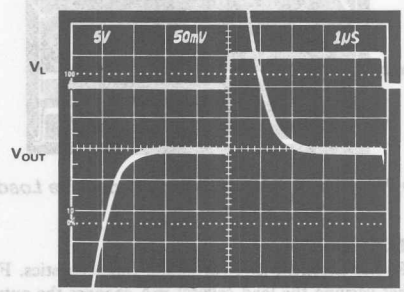

Figure 6b. Large-Scale Transient Response

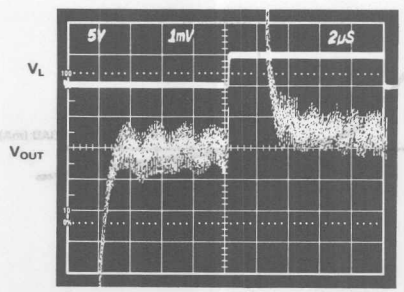

Figure 6c. Fine-Scale Settling for Transient Load

6

In some applications, a varying load may be both resistive and capacitive in nature, or the load may be connected to the AD586 by a long capacitive cable.

Figure 7 displays the output amplifier characteristics driving a 1000pF, 0 to 10mA load.

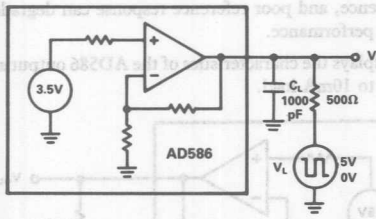

Figure 7a. Capacitive Load Transient Response Test Circuit

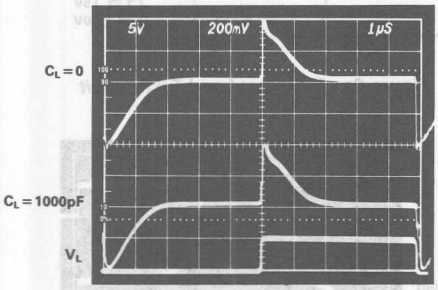

Figure 7b. Output Response with Capacitive Load

LOAD REGULATION

The AD586 has excellent load regulation characteristics. Figure 8 shows that varying the load several mA changes the output by a few μV. The AD586 has somewhat better load regulation performance sourcing current than sinking current.

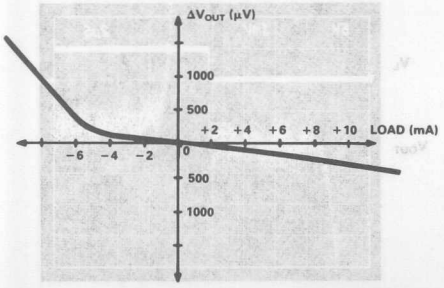

Figure 8. Typical Load Regulation Characteristics

TEMPERATURE PERFORMANCE

The AD586 is designed for precision reference applications where temperature performance is critical. Extensive temperature testing ensures that the device's high level of performance is maintained over the operating temperature range.

Some confusion exists in the area of defining and specifying reference voltage error over temperature. Historically, references have been characterized using a maximum deviation per degree Centrigrade; i.e., ppm/°C. However, because of nonlinearities in temperature characteristics which originated in standard Zener references (such as "S" type characteristics), most manufacturers have begun to use a maximum limit error band approach to specify devices. This technique involves the measurement of the output at three or more different temperatures to specify an output voltage error band.

Figure 9 shows the typical output voltage drift for the AD586L and illustrates the test methodology. The box in Figure 9 is bounded on the sides by the operating temperature extremes, and on the top and the bottom by the maximum and minimum output voltages measured over the operating temperature range. The slope of the diagonal drawn from the lower left to the upper right corner of the box determines the performance grade of the device.

$$\text{SLOPE} = \text{T.C.} = \frac{V_{max} - V_{min}}{(T_{max} - T_{min}) \times 5 \times 10^{-6}}$$

$$= \frac{5.0027 - 5.0012}{(70°C - 0) \times 5 \times 10^{-6}}$$

$$= 4.3\text{ppm/°C}$$

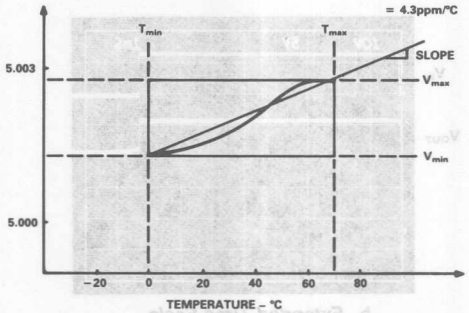

Figure 9. Typical AD586L Temperature Drift

Each AD586JQ, KQ and LQ grade unit is tested at 0, +25°C and +70°C. Each AD586SQ and TQ grade unit is tested at −55°C, +25°C and +125°C. This approach ensures that the variations of output voltage that occur as the temperature changes within the specified range will be contained within a box whose diagonal has a slope equal to the maximum specified drift. The position of the box on the vertical scale will change from device to device as initial error and the shape of the curve vary. The maximum height of the box for the appropriate temperature range and device grade is shown in Figure 10. Duplication of these results requires a combination of high accuracy and stable temperature control in a test system. Evaluation of the AD586 will produce a curve similar to that in Figure 9, but output readings may vary depending on the test methods and equipment utilized.

DEVICE GRADE	MAXIMUM OUTPUT CHANGE (mV)	
	0 TO +70°C	−55°C TO +125°C
AD586J	8.75	
AD586K	5.25	
AD586L	1.75	
AD586M	0.70	
AD586S		18.00
AD586T		9.00

Figure 10. Maximum Output Change in mV

NEGATIVE REFERENCE VOLTAGE FROM AN AD586

The AD586 can be used to provide a precision −5.000V output as shown in Figure 11. The V_{IN} pin is tied to at least a +6V supply, the output pin is grounded, and the AD586 ground pin is connected through a resistor, R_S, to a −15V supply. The −5V output is now taken from the ground pin (Pin 4) instead of V_{OUT}. It is essential to arrange the output load and the supply resistor R_S so that the net current through the AD586 is between 2.5mA and 10.0mA. The temperature characteristics and long-term stability of the device will be essentially the same as that of a unit used in the standard +5V output configuration.

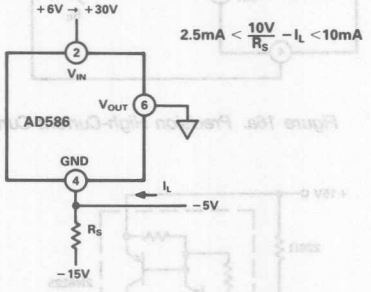

Figure 11. AD586 as a Negative 5V Reference

USING THE AD586 WITH CONVERTERS

The AD586 is an ideal reference for a wide variety of 8-, 12-, 14- and 16-bit A/D and D/A converters. Several representative examples follow.

5V REFERENCE WITH MULTIPLYING CMOS D/A OR A/D CONVERTERS

The AD586 is ideal for applications with 10- and 12-bit multiplying CMOS D/A converters. In the standard hookup, as shown in Figure 12, the AD586 is paired with the AD7545 12-bit multiplying DAC and the AD711 high-speed BiFET Op Amp. The amplifier DAC configuration produces a unipolar 0 to −5V output range. Bipolar output applications and other operating details can be found on the individual product data sheets.

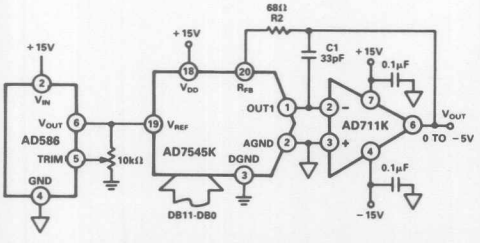

Figure 12. Low-Power 12-Bit CMOS DAC Application

The AD586 can also be used as a precision reference for multiple DACs. Figure 13 shows the AD586, the AD7628 dual DAC and the AD712 dual op amp hooked up for single supply operation to produce 0 to −5V outputs. Because both DACs are on the same die and share a common reference and output op amps, the DAC outputs will exhibit similar gain TCs.

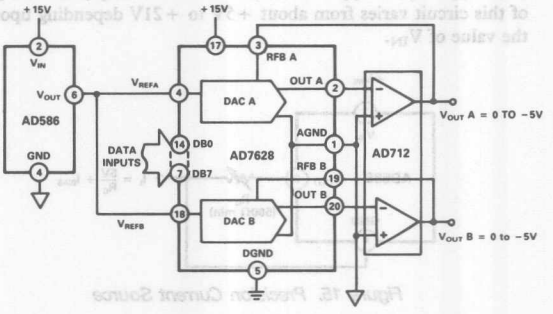

Figure 13. AD586 as a 5V Reference for a CMOS Dual DAC

STACKED PRECISION REFERENCES FOR MULTIPLE VOLTAGES

Often, a design requires several reference voltages. Three AD586s can be stacked, as shown in Figure 14, to produce +5.000V, +10.000V, and +15.000V outputs. This scheme can be extended to any number of AD586s as long as the maximum load current is not exceeded. This design provides the additional advantage of improved line regulation on the +5.0V output. Changes in V_{IN} of +18V to +50V produces an output change that is below the noise level of the references.

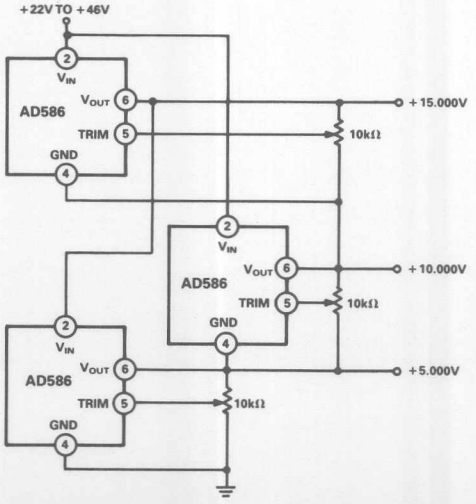

Figure 14. Multiple AD586s Stacked for Precision 5V, 10V and 15V Outputs

PRECISION CURRENT SOURCE

The design of the AD586 allows it to be easily configured as a current source. By choosing the control resistor R_C in Figure 15, you can vary the load current from the quiescent current (2mA typically) to approximately 10mA. The compliance voltage of this circuit varies from about +5V to +21V depending upon the value of V_{IN}.

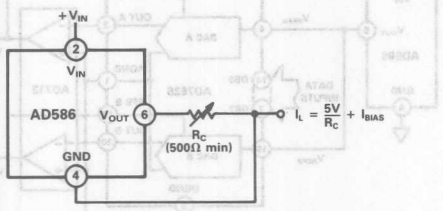

Figure 15. Precision Current Source

PRECISION HIGH CURRENT SUPPLY

For higher currents, the AD586 can easily be connected to a power PNP or power Darlington PNP device. The circuit in Figure 16 can deliver up to 4 amps to the load. The 0.1μF capacitor is required only if the load has a significant capacitive component. If the load is purely resistive, improved high-frequency supply rejection results can be obtained by removing the capacitor.

AD587

FEATURES

- Laser Trimmed to High Accuracy:
  10.000V ±5mV (L and U Grades)
- Trimmed Temperature Coefficient:
  5ppm/°C max, (L and U Grades)
- Noise Reduction Capability
- Low Quiescent Current: 4mA max
- Output Trim Capability
- MIL-STD-883 Compliant Versions Available

FUNCTIONAL BLOCK DIAGRAM

NOTE: PINS 1, 3 & 7 ARE INTERNAL TEST POINTS.
NO CONNECTIONS TO THESE POINTS.

PRODUCT DESCRIPTION

The AD587 represents a major advance in the state-of-the-art in monolithic voltage references. Using a proprietary ion-implanted buried Zener diode and laser wafer trimming of high stability thin-film resistors, the AD587 provides outstanding performance at low cost.

The AD587 offers much higher performance than most other 10V references. Because the AD587 uses an industry standard pinout, many systems can be upgraded instantly with the AD587. The buried Zener approach to reference design provides lower noise and drift than band-gap voltage references. The AD587 offers a noise reduction pin which can be used to further reduce the noise level generated by the buried Zener.

The AD587 is recommended for use as a reference for 8-, 10-, 12-, 14- or 16-bit D/A converters which require an external precision reference. The device is also ideal for successive approximation or integrating A/D converters with up to 14 bits of accuracy and, in general, can offer better performance than the standard on-chip references.

The AD587J, K and L are specified for operation from 0 to +70°C, and the AD587S, T and U are specified for −55°C to +125°C operation. All grades are available in 8-pin cerdip. The J and K versions are also available in an 8-pin Small Outline IC (SOIC) package for surface mount applications, while the J, K and L grades also come in an 8-pin plastic package.

PRODUCT HIGHLIGHTS

1. Laser trimming of both initial accuracy and temperature coefficients results in very low errors over temperature without the use of external components. The AD587L has a maximum deviation from 10.000V of ±8.5mV between 0 and +70°C, and the AD587U guarantees ±14mV maximum total error between −55°C and +125°C.
2. For applications requiring higher precision, an optional fine-trim connection is provided.
3. Any system using an industry standard pinout 10 volt reference can be upgraded instantly with the AD587.
4. Output noise of the AD587 is very low, typically 4μV p-p. A noise reduction pin is provided for additional noise filtering using an external capacitor.
5. The AD587 is available in versions compliant with MIL-STD-883. Refer to the Analog Devices Military Products Databook or current AD587/883B data sheet for detailed specifications.

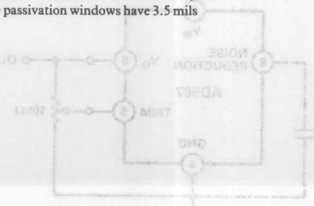
DIE LAYOUT

Die Size: 0.081 × 0.060 inches

NOTES
[1]Both V_{OUT} pads should be connected to the output.
[2]Sense and force grounds must be tied together.

Die Thickness: The standard thickness of Analog Devices Bipolar dice is 24 mils ± 2 mils.

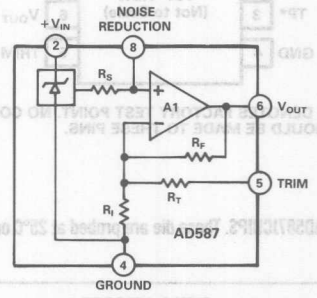
Die Dimensions: The dimensions given have a tolerance of ± 2 mils.



Backing: The standard backside surface is silicon (not plated). Analog Devices does not recommend gold-backed dice for most applications.

Edges: A diamond saw is used to separate wafers into dice thus providing perpendicular edges half-way through the die. In contrast to scribed dice, this technique provides a more uniform die shape and size. The perpendicular edges facilitate handling (such as tweezer pick-up) while the uniform shape and size simplifies substrate design and die attach.

Top Surface: The standard top surface of the die is covered by a layer of glassivation. All areas are covered except bonding pads and scribe lines.



Surface Metalization: The metalization to Analog Devices bipolar dice is aluminum. Minimum thickness is 10,000Å.

Bonding Pads: All bonding pads have a minimum size of 4 mils by 4 mils. The passivation windows have 3.5 mils by 3.5 mils minimum.

THEORY OF OPERATION

The AD587 consists of a proprietary buried Zener diode reference, an amplifier to buffer the output and several high stability thin-film resistors as shown in the block diagram in Figure 1. This design results in a high precision monolithic 10V output reference with initial offset of 5mV or less. The temperature compensation circuitry provides the device with a temperature coefficient of under 5ppm/°C.

NOTE: PINS 1, 3 & 7 ARE INTERNAL TEST POINTS. NO CONNECTIONS TO THESE POINTS.

Figure 1. AD587 Functional Block Diagram

A capacitor can be added at the NOISE REDUCTION pin (Pin 8) to form a low pass filter with R_S to reduce the noise contribution of the Zener to the circuit.

APPLYING THE AD587

The AD587 is simple to use in virtually all precision reference applications. When power is applied to Pin 2, and Pin 4 is grounded, Pin 6 provides a 10V output. No external components are required; the degree of desired absolute accuracy is achieved simply by selecting the required device grade. The AD587 requires less than 4mA quiescent current from an operating supply of +15V.

Fine trimming may be desired to set the output level to exactly 10.000V (calibrated to a main system reference). System calibration may also require a reference voltage that is slightly different from 10.000V, for example, 10.24V for binary applications. In either case, the optional trim circuit shown in Figure 2 can offset the output by as much as 300mV, if desired, with minimal effect on other device characteristics.

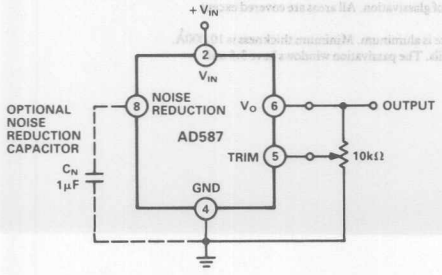


Figure 2. Optional Fine Trim Configuration

NOISE PERFORMANCE AND REDUCTION

The noise generated by the AD587 is typically less than 4μV p-p over the 0.1Hz to 10Hz band. Noise in a 1MHz bandwidth is approximately 200μV p-p. The dominant source of this noise is the buried Zener which contributes approximately 100nV/$\sqrt{\text{Hz}}$. In comparison, the op amp's contribution is negligible. Figure 3 shows the 0.1Hz to 10Hz noise of a typical AD587. The noise measurement is made with a bandpass filter made of a 1-pole high-pass filter with a corner frequency at 0.1Hz and a 2-pole low-pass filter with a corner frequency at 12.6Hz to create a filter with a 9.922Hz bandwidth.

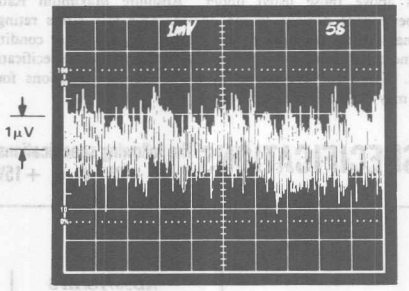

Figure 3. 0.1Hz to 10Hz Noise

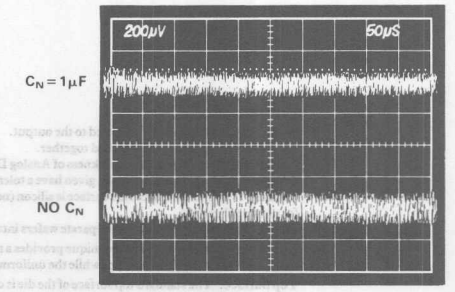
If further noise reduction is desired, an external capacitor may be added between the NOISE REDUCTION pin and ground as shown in Figure 2. This capacitor, combined with the 4kΩ R_S and the Zener resistances, form a low-pass filter on the output of the Zener cell. A 1μF capacitor will have a 3dB point at 40Hz, and it will reduce the high-frequency (to 1MHz) noise to about 160μV p-p. Figure 4 shows the 1MHz noise of a typical AD587 both with and without a 1μF capacitor.



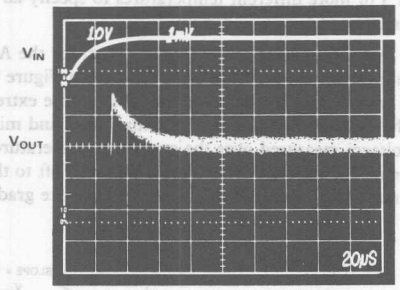


Figure 4. Effect of 1μF Noise Reduction Capacitor on Broadband Noise

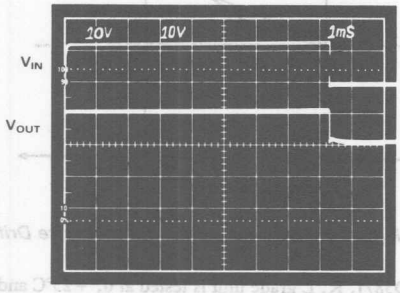
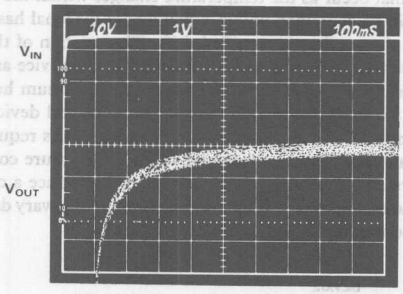


TURN-ON TIME

Upon application of power (cold start), the time required for the output voltage to reach its final value within a specified error band is defined as the turn-on settling time. Two components normally associated with this are: the time for the active circuits to settle, and the time for the thermal gradients on the chip to stabilize. Figure 5 shows the turn-on characteristics of the AD587. It shows the settling to be about 60μs to 0.01%. Note the absence of any thermal tails when the horizontal scale is expanded to 1ms/cm in Figure 5b.



Output turn-on time is modified when an external noise reduction capacitor is used. When present, this capacitor acts as an additional load to the internal Zener diode's current source, resulting in a somewhat longer turn-on time. In the case of a 1μF capacitor, the initial turn-on time is approximately 400ms to 0.01% (see Figure 5c).

DYNAMIC PERFORMANCE

The output buffer amplifier is designed to provide the AD587 with static and dynamic load regulation superior to less complete references.

Many A/D and D/A converters present transient current loads to the reference, and poor reference response can degrade the converter's performance.

Figure 6 displays the characteristics of the AD587 output amplifier driving a 0 to 10mA load.

LOAD REGULATION

The AD587 has excellent load regulation characteristics. Figure 8 shows that varying the load several mA changes the output by only a few μV.

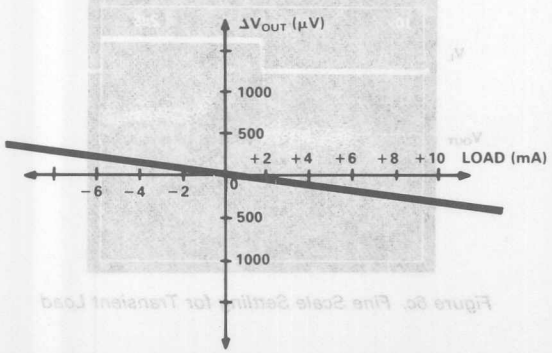

Figure 8. Typical Load Regulation Characteristics

TEMPERATURE PERFORMANCE

The AD587 is designed for precision reference applications where temperature performance is critical. Extensive temperature testing ensures that the device's high level of performance is maintained over the operating temperature range.

reference voltage error over temperature. Historically, references have been characterized using a maximum deviation per degree Centrigrade; i.e., ppm/°C. However, because of nonlinearities in temperature characteristics which originated in standard Zener references (such as "S" type characteristics), most manufacturers have begun to use a maximum limit error band approach to specify devices. This technique involves the measurement of the output at 3 or more different temperatures to specify an output voltage error band.

Figure 9 shows the typical output voltage drift for the AD587L and illustrates the test methodology. The box in Figure 9 is bounded on the sides by the operating temperature extremes, and on the top and the bottom by the maximum and minimum output voltages measured over the operating temperature range. The slope of the diagonal drawn from the lower left to the upper right corner of the box determines the performance grade of the device.

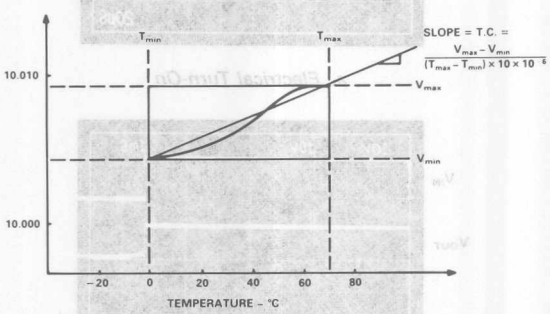

Figure 9. Typical AD587L Temperature Drift

Each AD587J, K, L grade unit is tested at 0, +25°C and +70°C. Each AD587S, T, and U grade unit is tested at −55°C, +25°C and +125°C. This approach ensures that the variations of output voltage that occur as the temperature changes within the specified range will be contained within a box whose diagonal has a slope equal to the maximum specified drift. The position of the box on the vertical scale will change from device to device as initial error and the shape of the curve vary. The maximum height of the box for the appropriate temperature range and device grade is shown in Figure 10. Duplication of these results requires a combination of high accuracy and stable temperature control in a test system. Evaluation of the AD587 will produce a curve similar to that in Figure 9, but output readings may vary depending on the test methods and equipment utilized.

DEVICE GRADE	MAXIMUM OUTPUT CHANGE – mV	
	0 TO +70°C	−55°C TO +125°C
AD587J	14.00	
AD587K	7.00	
AD587L	3.50

AD587T		18.00
AD587U		9.00

Figure 10. Maximum Output Change in mV

NEGATIVE REFERENCE VOLTAGE FROM AN AD587

The AD587 can be used to provide a precision −10.000V output as shown in Figure 11. The V_{IN} pin is tied to at least a +3.5V supply, the output pin is grounded, and the AD587 ground pin is connected through a resistor, R_S, to a −15V supply. The −10V output is now taken from the ground pin (Pin 4) instead of V_{OUT}. It is essential to arrange the output load and the supply resistor R_S so that the net current through the AD587 is between 2.5mA and 10.0mA. The temperature characteristics and long-term stability of the device will be essentially the same as that of a unit used in the standard +10V output configuration.

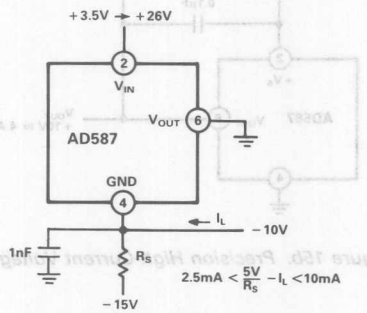

Figure 11. AD587 as a Negative 10V Reference

USING THE AD587 WITH CONVERTERS

The AD587 is an ideal reference for a wide variety of 8-, 12-, 14- and 16-bit A/D and D/A converters. Several representative examples follow.

10V REFERENCE WITH MULTIPLYING CMOS D/A OR A/D CONVERTERS

The AD587 is ideal for applications with 10- and 12-bit multiplying CMOS D/A converters. In the standard hookup, as shown in Figure 12, the AD587 is paired with the AD7545 12-bit multiplying DAC and the AD711 high-speed BiFET Op Amp. The amplifier DAC configuration produces a unipolar 0 to −10V output range. Bipolar output applications and other operating details can be found on the individual product data sheets.

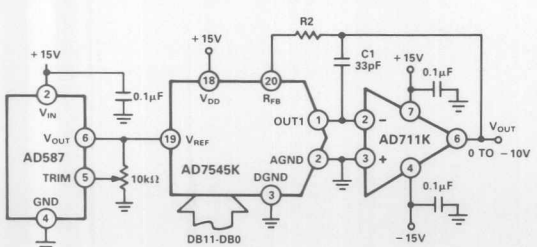

Figure 12. Low-Power 12-Bit CMOS DAC Application

The AD587 can also be used as a precision reference for multiple DACs. Figure 13 shows the AD587, the AD7628 dual DAC and the AD712 dual op amp hooked up for single supply operation to produce 0 to −10V outputs. Because both DACs are on the same die and share a common reference and output op amps; the DAC outputs will exhibit similar gain TCs.

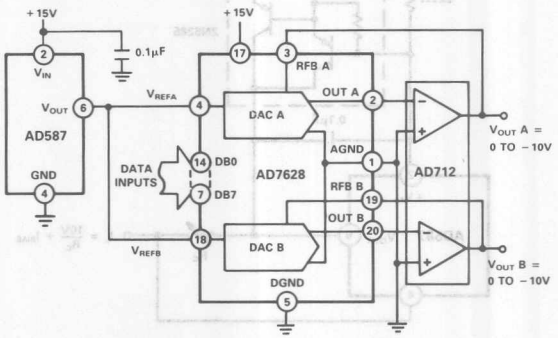

Figure 13. AD587 as a 10V Reference for a CMOS Dual DAC

PRECISION CURRENT SOURCE

The design of the AD587 allows it to be easily configured as a current source. By choosing the control resistor R_C in Figure 14, you can vary the load current from the quiescent current (2mA typically) to approximately 10mA.

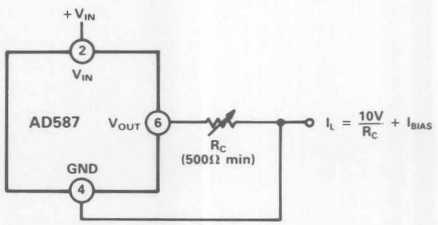

Figure 14. Precision Current Source

PRECISION HIGH CURRENT SUPPLY

For higher currents, the AD587 can easily be connected to a power PNP or power Darlington PNP device. The circuit in Figure 15 can deliver up to 4 amps to the load. The 0.1μF capacitor is required only if the load has a significant capacitive component. If the load is purely resistive, improved high-frequency supply rejection results can be obtained by removing the capacitor.

PRODUCT DESCRIPTION

The AD588 represents a major advance in the state-of-the-art in monolithic voltage references. Low initial error and low temperature drift give the AD588 absolute accuracy performance previously not available in monolithic form. The AD588 uses a proprietary ion-implanted buried Zener diode, and laser-wafer-drift-trimming of high stability thin-film resistors to provide outstanding performance at low cost.

The AD588 includes the basic reference cell and three additional amplifiers which provide pin-programmable output ranges. The amplifiers are laser-trimmed for low offset and low drift to maintain the accuracy of the reference. The amplifiers are configured to allow Kelvin connections to the load and/or boosters for driving long lines or high-current loads, delivering the full accuracy of the AD588 where it is required in the application circuit.

The low initial error allows the AD588 to be used as a system reference in precision measurement applications requiring 12-bit absolute accuracy. In such systems, the AD588 can provide a known voltage for system calibration in software and the low drift allows compensation for the drift of other components in a system. Manual system calibration and the cost of periodic recalibration can therefore be eliminated. Furthermore, the mechanical instability of a trimming potentiometer and the potential for improper calibration can be eliminated by using the AD588 in conjunction autocalibration software.

The AD588 is available in seven versions. The AD588 JQ and KQ grades are packaged in a 16-pin cerdip and are specified for 0 to +70°C operation. AD588AD and BD grades are packaged in a 16-pin side-brazed ceramic DIP and are specified for the –25°C to +85°C industrial temperature range. The ceramic AD588SD and TD grades are specified for the full military/aerospace temperature range. For military surface mount applications. the AD588SE and TE grades will also be available in 20-pin LCC packages.

*Covered by Patent Number 4,644,253

PRODUCT HIGHLIGHTS

1. The AD588 offers 12-bit absolute accuracy without any user adjustments. Optional fine-trim connections are provided for applications requiring higher precision. The fine-trimming does not alter the operating conditions of the Zener or the buffer amplifiers and thus does not increase the temperature drift.
2. Output noise of the AD588 is very low – typically 6μV p-p. A pin is provided for additional noise filtering using an external capacitor.
3. A precision ±5V tracking mode with Kelvin output connections is available with no external components. Tracking error is less than one millivolt and a fine-trim is available for applications requiring exact symmetry between the +5V and –5V outputs.
4. Pin strapping capability allows configuration of a wide variety of outputs: ±5V, +5V & +10V, –5V & –10V dual outputs or +5V, –5V, +10V, –10V single outputs.
5. Extensive temperature testing at –55°C, –25°C, 0, +25°C, +50°C, +70°C, +85°C and +125°C ensures that the specified temperature coefficient is truly representative of device performance.

NC = NO CONNECT

THEORY OF OPERATION

The AD588 consists of a buried Zener diode reference, amplifiers used to provide pin programmable output ranges, and associated thin-film resistors as shown in the block diagram of Figure 1. The temperature compensation circuitry provides the device with a temperature coefficient of 1.5ppm/°C or less.

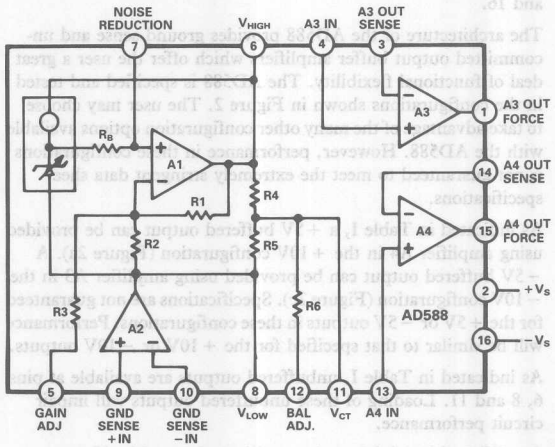

Figure 1. AD588 Functional Block Diagram

Amplifier A1 performs several functions. A1 primarily acts to amplify the Zener voltage from 6.5V to the required 10V output. In addition, A1 also provides for external adjustment of the 10V output through pin 5, the GAIN ADJUST. Using the bias compensation resistor between the Zener output and the non-inverting input to A1, a capacitor can be added at the NOISE REDUCTION pin (pin 7) to form a low pass filter and reduce the noise contribution of the Zener to the circuit. Two matched 10kΩ nominal thin film resistors (R4 & R5) divide the 10V output in half. Pin V_{CT} (pin 11) provides access to the center of the voltage span and pin 12 (BALANCE ADJUST) can be used for fine adjustment of this division.

Ground sensing for the circuit is provided by amplifier A2. The noninverting input (pin 9) senses the system ground which will be transferred to the point on the circuit where the inverting input (pin 10) is connected. This may be pin 6, 8 or 11. The output of A2 drives pin 8 to the appropriate voltage. Thus, if pin 10 is connected to pin 8, the V_{LOW} pin will be the same voltage as the system ground. Alternatively, if pin 10 is connected to the V_{CT} pin, it will be ground and pin 6 and pin 8 will be +5V and −5V respectively.

Amplifiers A3 and A4 are internally compensated and are used to buffer the voltages at pins 6, 8 and 11 as well as to provide a full Kelvin output. Thus, the AD588 has a full Kelvin capability by providing the means to sense a system ground and provide forced and sensed outputs referenced to that ground.

6

APPLYING THE AD588

The AD588 can be configured to provide +10V and −10V reference outputs as shown in Figures 2a and 2c respectively. It can also be used to provide +5V, −5V or a ±5V tracking reference as shown in Figure 2b. Table I details the appropriate pin connections for each output range. In each case, pin 9 is connected to system ground and power is applied to pins 2 and 16.

The architecture of the AD588 provides ground sense and uncommitted output buffer amplifiers which offer the user a great deal of functional flexibility. The AD588 is specified and tested in the configurations shown in Figure 2. The user may choose to take advantage of the many other configuration options available with the AD588. However, performance in these configurations is not guaranteed to meet the extremely stringent data sheet specifications.

As indicated in Table I, a +5V buffered output can be provided using amplifier A4 in the +10V configuration (Figure 2a). A −5V buffered output can be provided using amplifier A3 in the −10V configuration (Figure 2c). Specifications are not guaranteed for the +5V or −5V outputs in these configurations. Performance will be similar to that specified for the +10V or −10V outputs.

As indicated in Table I, unbuffered outputs are available at pins 6, 8 and 11. Loading of these unbuffered outputs will impair circuit performance.

Amplifiers A3 and A4 can be used interchangeably. However, the AD588 is tested (and the specifications are guaranteed) with the amplifiers connected as indicated in Figure 2 and Table I. When either A3 or A4 is unused, its output force and sense pins should be connected and the input tied to ground.

Two outputs of the same voltage may be obtained by connecting both A3 and A4 to the appropriate unbuffered output on pin 6, 8 or 11. Performance in these dual output configurations will typically meet data sheet specifications.

CALIBRATION

Generally, the AD588 will meet the requirements of a precision system without additional adjustment. Initial output voltage error of 1mV and output noise specs of 10μV p-p allow for accuracies of 12-16 bits. However, in applications where an even greater level of accuracy is required, additional calibration may be called for. Provision for trimming has been made through the use of the GAIN ADJUST and BALANCE ADJUST pins (pins 5 and 12 respectively).

The AD588 provides a precision 10V span with a center tap (V_{CT}) which is used with the buffer and ground sense amplifiers to achieve the voltage output configurations in Table I. GAIN ADJUST and BALANCE ADJUST can be used in any of these configurations to trim the magnitude of the span voltage and the position of the center tap within the span. The GAIN ADJUST should be performed first. Although the trims are not interactive within the device, the GAIN trim will move the BALANCE trim point as it changes the magnitude of the span.

Figure 2b. shows GAIN and BALANCE trims in a +5V and −5V tracking configuration. A 100kΩ 20-turn potentiometer is used for each trim. The potentiometer for GAIN trim is connected between pins 6 (V_{HIGH}) and 8 (V_{LOW}) with the wiper connected to pin 5 (GAIN ADJ). The potentiometer is adjusted to produce exactly 10V between pins 1 and 15, the amplifier outputs. The BALANCE potentiometer, also connected between pins 6 and 8 with the wiper to pin 12 (BAL ADJ), is then adjusted to center the span from +5V to −5V.

Trimming in other configurations works in exactly the same manner. When producing +10V and +5V, GAIN ADJ is used to trim +10V and BAL ADJ is used to trim +5V. In the −10V and −5V configuration, GAIN ADJ is again used to trim the magnitude of the span, −10V, while BAL ADJ is used to trim the center tap, −5V.

Range	Connect Pin 10 to Pin:	Unbuffered[1] Output on Pins −10V	−5V	0V	+5V	+10V	Buffered Output Connections	Buffered Output on Pins −10V	−5V	0V	+5V	+10V
+10V	8	–	–	8	11	6	11-13 & 14-15	–	–	–	15	–
							6-4 & 3-1	–	–	–	–	1
−5V or +5V	11	–	8	11	6	–	8-13 & 14-15	–	15	–	–	–
							6-4 & 3-1	–	–	–	1	–
−10V	6	8	11	6	–	–	8-13 & 14-15	15	–	–	–	–
							11-4 & 3-1	–	1	–	–	–
+5V	11	–	–	–	6	–	6-4 & 3-1	–	–	–	1	–
−5V		–	8	–	–	–	8-13 & 14-15	–	15	–	–	–

[1]"Unbuffered" outputs should not be loaded.

Table I. AD588 Connections

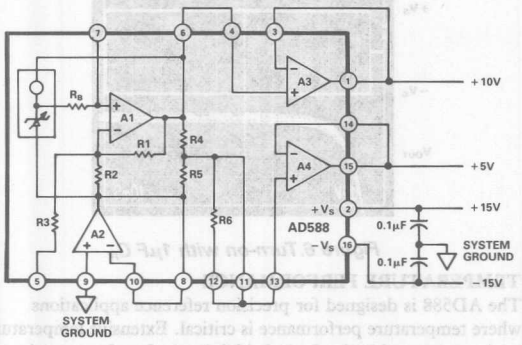

Figure 2a. +10V Output

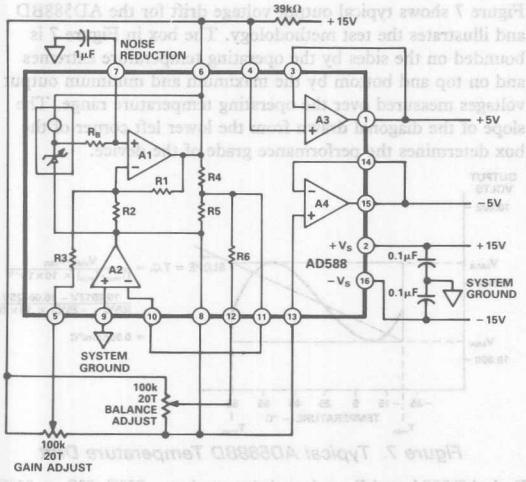

Figure 2b. +5V and –5V Outputs

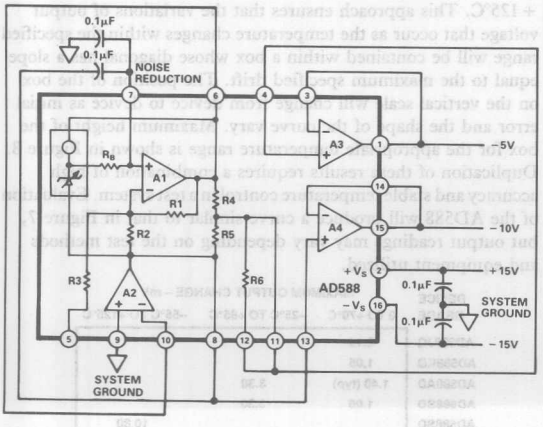

Figure 2c. –10V Output

In single output configurations, GAIN ADJ is used to trim outputs utilizing the full span (+10V or –10V) while BAL ADJ is used to trim outputs using half the span (+5V or –5V).

Input impedance on both the GAIN ADJUST and BALANCE ADJUST pins is approximately 150kΩ. The GAIN ADJUST trim network effectively attenuates the 10V across the trim potentiometer by a factor of about 1500 to provide a trim range of –3.5mV to +7.5mV with a resolution of approximately 550μV/turn (20 turn potentiometer). The BALANCE ADJUST trim network attenuates the trim voltage by a factor of about 1400, providing a trim range of ±4.5mV with resolution of 450μV/turn.

Trimming the AD588 introduces no additional errors over temperature so precision potentiometers are not required.

For single output voltage ranges, or in cases when BALANCE ADJUST is not required, pin 12 should be connected to pin 11. If GAIN ADJUST is not required, pin 5 should be left floating.

NOISE PERFORMANCE AND REDUCTION

The noise generated by the AD588 is typically less than 6μV p-p over the 0.1Hz to 10Hz band. Noise in a 1MHz bandwidth is approximately 600μV p-p. The dominant source of this noise is the buried Zener which contributes approximately 100nV/$\sqrt{\text{Hz}}$. In comparison, the op amp's contribution is negligible. Figure 3 shows the 0.1Hz to 10Hz noise of a typical AD588.

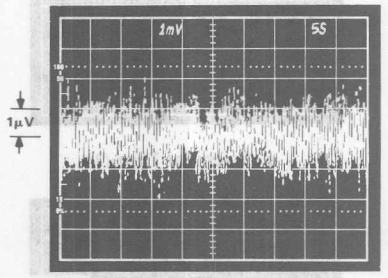

Figure 3. 0.1Hz to 10Hz Noise

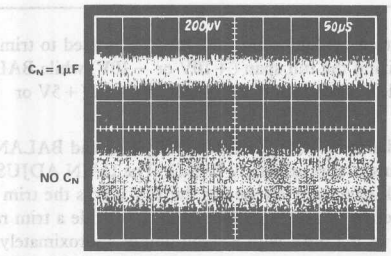
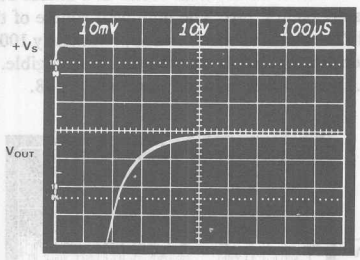
If further noise reduction is desired, an optional capacitor may be added between the NOISE REDUCTION pin and ground as shown in Figure 2b. This will form a low pass filter with the 4kΩ R_B on the output of the Zener cell. A 1μF capacitor will have a 3dB point at 40Hz and will reduce the high frequency (to 1MHz) noise to about 200μV p-p. Figure 4 shows the 1MHz noise of a typical AD588 both with and without a 1μF capacitor.

Note that a second capacitor is needed in order to implement the NOISE REDUCTION feature when using the AD588 in the –10V mode (Figure 2c.). The NOISE REDUCTION capacitor is limited to 0.1μF maximum in this mode.

6





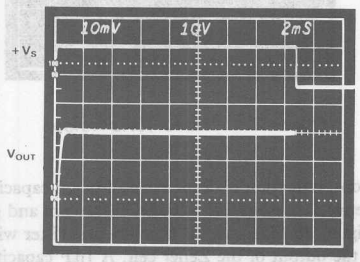


Figure 4. Effect of 1μF Noise Reduction Capacitor on Broadband Noise

TURN-ON TIME

Upon application of power (cold start), the time required for the output voltage to reach its final value within a specified error band is the turn-on settling time. Two components normally associated with this are: time for active circuits to settle and time for thermal gradients on the chip to stabilize. Figure 5 shows the turn-on characteristics of the AD588. It shows the settling to be about 600μs. Note the absence of any thermal tails when the horizontal scale is expanded to 2ms/cm in Figure 5b.

a. Electrical Turn-On

b. Extended Time Scale

Figure 5. Turn-On Characteristics

Output turn-on time is modified when an external noise reduction capacitor is used. When present, this capacitor presents an additional load to the internal Zener diode's current source, resulting in a somewhat longer turn-on time. In the case of a 1μF capacitor, the initial turn-on time is approximately 60ms (see Figure 6).

Note: If the NOISE REDUCTION feature is used in the ±5V configuration, a 39kΩ resistor between pins 6 and 2 is required for proper startup.

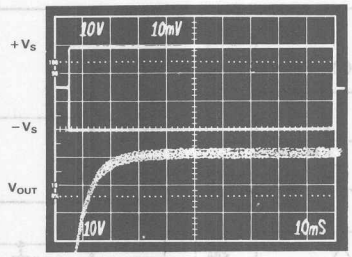

Figure 6. Turn-on with 1μF C_N

TEMPERATURE PERFORMANCE

The AD588 is designed for precision reference applications where temperature performance is critical. Extensive temperature testing ensures that the device's high level of performance is maintained over the operating temperature range.

Figure 7 shows typical output voltage drift for the AD588BD and illustrates the test methodology. The box in Figure 7 is bounded on the sides by the operating temperature extremes and on top and bottom by the maximum and minimum output voltages measured over the operating temperature range. The slope of the diagonal drawn from the lower left corner of the box determines the performance grade of the device.

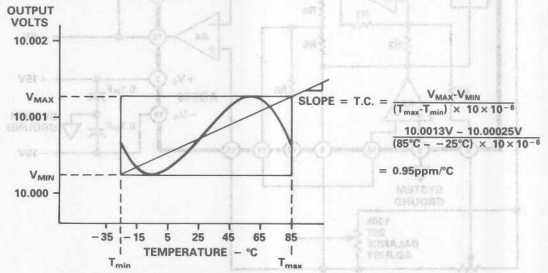

Figure 7. Typical AD588BD Temperature Drift

Each AD588A and B grade unit is tested at −25°C, 0°C, +25°C, +50°C, +70°C and +85°C. Each AD588S and T grade unit is tested at −55°C, −25°C, 0°C, +25°C, +50°C, +70°C and +125°C. This approach ensures that the variations of output voltage that occur as the temperature changes within the specified range will be contained within a box whose diagonal has a slope equal to the maximum specified drift. The position of the box on the vertical scale will change from device to device as initial error and the shape of the curve vary. Maximum height of the box for the appropriate temperature range is shown in Figure 8. Duplication of these results requires a combination of high accuracy and stable temperature control in a test system. Evaluation of the AD588 will produce a curve similar to that in Figure 7, but output readings may vary depending on the test methods and equipment utilized.

DEVICE GRADE	MAXIMUM OUTPUT CHANGE – mV		
	0 TO +70°C	−25°C TO +85°C	−55°C TO +125°C
AD588JQ	2.10		
AD588KQ	1.05		
AD588AD	1.40 (typ)	3.30	
AD588BD	1.05	3.30	
AD588SD			10.80
AD588TD			7.20

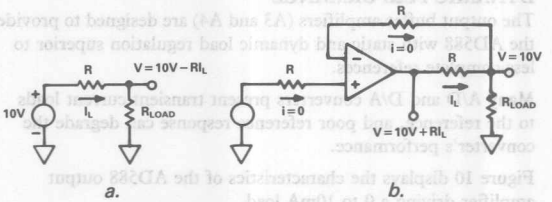
Figure 8. Maximum Output Change – mV

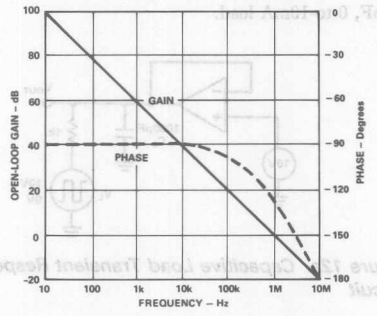
KELVIN CONNECTIONS

Force and sense connections, also referred to as Kelvin connections, offer a convenient method of eliminating the effects of voltage drops in circuit wires. As seen in Figure 9a, the load current and wire resistance produce an error ($V_{ERROR} = R \times I_L$) at the load. The Kelvin connection of Figure 9b overcomes the problem by including the wire resistance within the forcing loop of the amplifier and sensing the load voltage. The amplifier corrects for any errors in the load voltage. In the circuit shown, the output of the amplifier would actually be at 10 volts + V_{ERROR} and the voltage at the load would be the desired 10 volts.

The AD588 has three amplifiers which can be used to implement Kelvin connections. Amplifier A2 is dedicated to the ground force-sense function while uncommitted amplifiers A3 and A4 are free for other force-sense chores.

In some single-output applications, one amplifier may be unused.





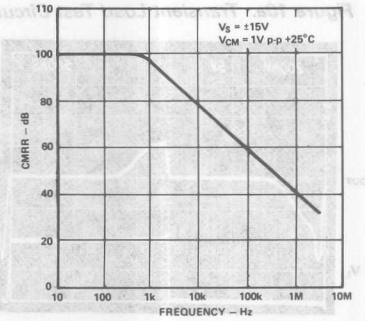


Figure 9. Advantage of Kelvin Connection

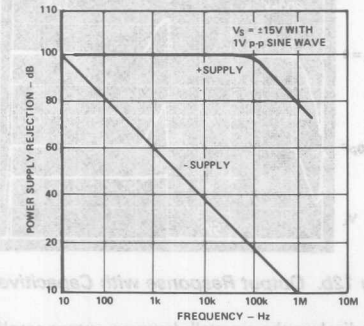
In such cases, the unused amplifier should be connected as a unity-gain follower (force + sense pin tied together) and the input should be connected to ground.



An unused amplifier section may be used for other circuit functions as well. The curves on this page show the typical performance of A3 and A4.

DYNAMIC PERFORMANCE

The output buffer amplifiers (A3 and A4) are designed to provide the AD588 with static and dynamic load regulation superior to less complete references.

Many A/D and D/A converters present transient current loads to the reference, and poor reference response can degrade the converter's performance.

Figure 10 displays the characteristics of the AD588 output amplifier driving a 0 to 10mA load.

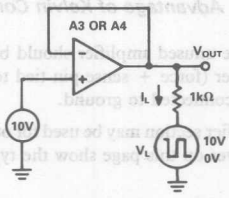

Figure 10a. Transient Load Test Circuit

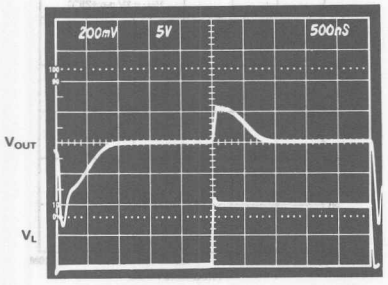

Figure 10b. Large-Scale Transient Response

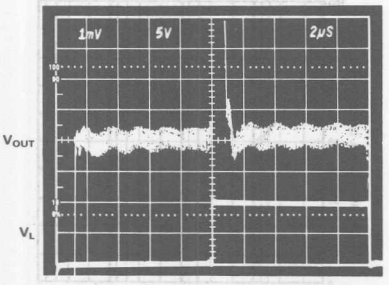

Figure 10c. Fine Scale Settling for Transient Load

Figure 11 displays the output amplifier characteristics driving a 5mA to 10mA load, a common situation found when the reference is shared among multiple converters or is used to provide a bipolar offset current.

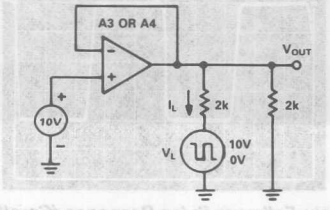

Figure 11a. Transient and Constant Load Test Circuit

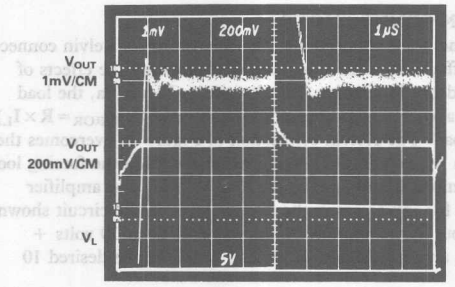

Figure 11b. Transient Response 5-10mA Load

In some applications, a varying load may be both resistive and capacitive in nature, or be connected to the AD588 by a long capacitive cable.

Figure 12 displays the output amplifier characteristics driving a 1,000pF, 0-to-10mA load.

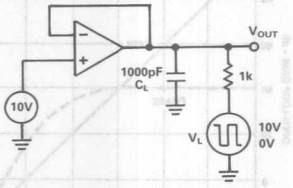

Figure 12a. Capacitive Load Transient Response Test Circuit

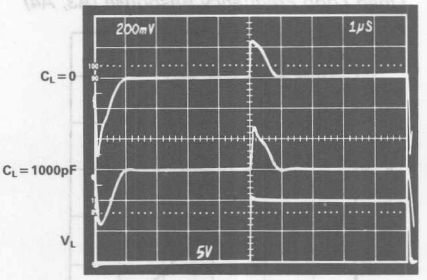

Figure 12b. Output Response with Capacitive Load

Figure 13 displays the crosstalk between output amplifiers. The top trace shows the output of A4, dc-coupled and offset by 10 volts, while the output of A3 is subjected to a 0-to-10mA load current step. The transient at A4 settles in about 1µs, and the load-induced offset is about 100µV.

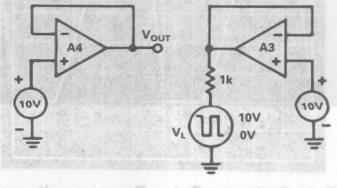

Figure 13a. Load Crosstalk Test Circuit

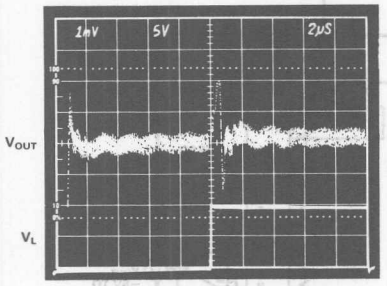

Figure 13b. Load Crosstalk

Attempts to drive a large capacitive load (in excess of 1,000pF) may result in ringing or oscillation, as shown in the step response photo (Figure 14a). This is due to the additional pole formed by the load capacitance and the output impedance of the amplifier, which consumes phase margin. The recommended method of driving capacitive loads of this magnitude is shown in Figure 14b. The 150Ω resistor isolates the capacitive load from the output stage, while the 10kΩ resistor provides a dc feedback path and preserves the output accuracy. The 1μF capacitor provides a high-frequency feedback loop. The performance of this circuit is shown in Figure 14c.

USING THE AD588 WITH CONVERTERS

The AD588 is an ideal reference for a wide variety of A/D and D/A converters. Several representative examples follow.

14-Bit Digital-to-Analog Converter – AD7535

High resolution CMOS D/A converters require a reference voltage of high precision to maintain rated accuracy. The combination of the AD588 and AD7535 takes advantage of the initial accuracy, drift and full Kelvin output capability of the AD588 as well as the resolution, monotonicity and accuracy of the AD7535 to produce a subsystem with outstanding characteristics.

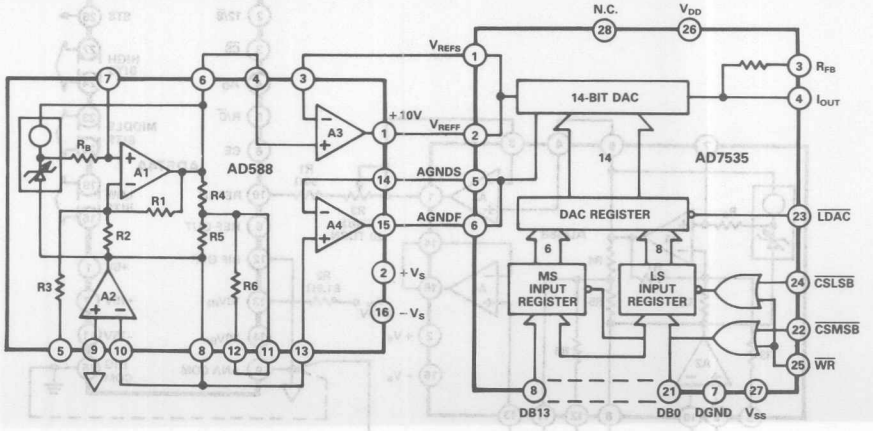

Figure 15. AD588/AD7535 Connections

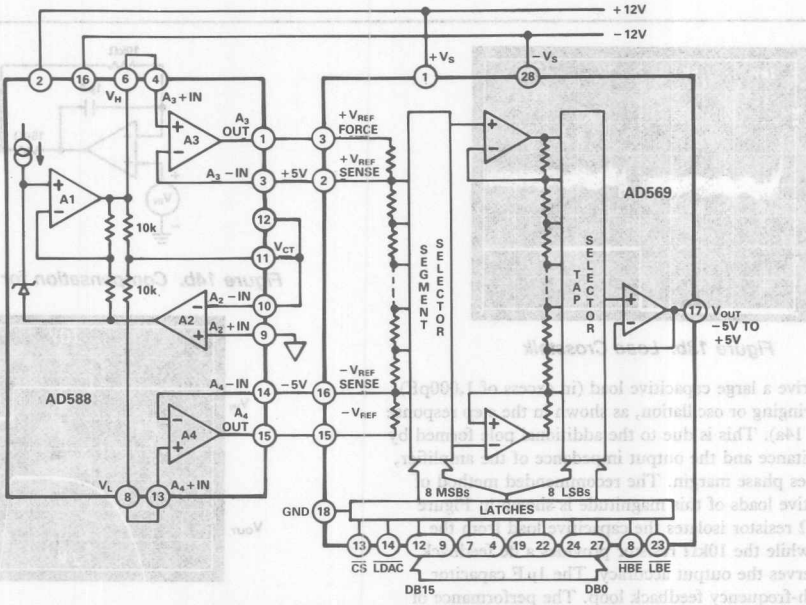

Figure 16. High-Accuracy ±5V Tracking Reference for AD569

16-Bit Digital-to-Analog Converter – AD569

Another application which fully utilizes the capabilities of the AD588 is supplying a reference for the AD569, as shown in Figure 16. Amplifier A2 senses system common and forces V_{CT} to assume this value, producing +5V and −5V at pins 6 and 8 respectively. Amplifiers A3 and A4 buffer these voltages out to the appropriate reference force-sense pins of the AD569. The full Kelvin scheme eliminates the effect of the circuit traces or wires and the wire bonds of the AD588 and AD569 themselves, which would otherwise degrade system performance.

SUBSTITUTING FOR INTERNAL REFERENCES

Many converters include built-in references. Unfortunately, such references are the major source of drift in these converters. By using a more stable external reference like the AD588, drift performance can be improved dramatically.

12-Bit Analog-to-Digital Converter – AD574A

The AD574A is specified for gain drift from 10ppm/°C to 50ppm/°C, (depending on grade) using the on-chip reference. The reference contributes typically 75% of this drift. Therefore, the total drift using an AD588 to supply the reference can be improved by a factor of 3 to 4.

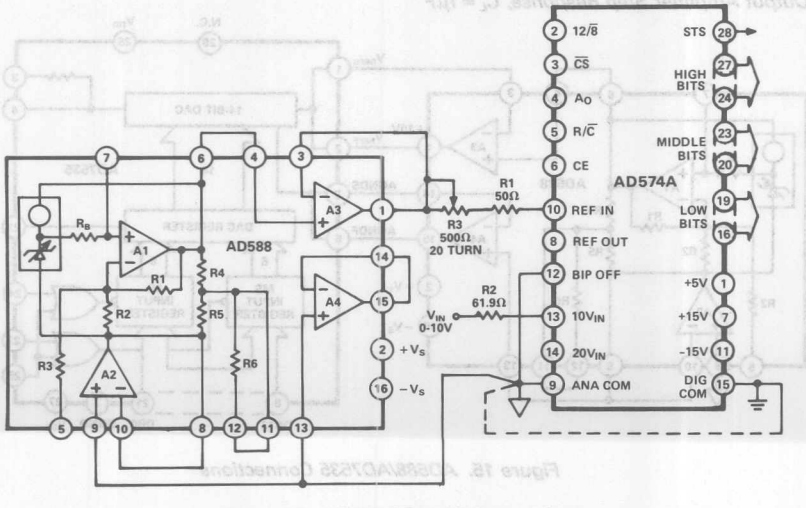

Figure 17. AD588/AD574A Connections

Using this combination may result in apparent increases in full-scale error due to the difference between the on-board reference by which the device is laser trimmed and the external reference with which the device is actually applied. The on-board reference is specified to be 10V ±100mV while the external reference is specified to be 10V ±1mV. This may result in up to 101mV of apparent full-scale error beyond the ±25mV specified AD574 gain error. Resistors R2 and R3 allow this error to be nulled. Their contribution to full-scale drift is negligible.

The high output drive capability allows the AD588 to drive up to 6 converters in a multi-converter system. All converters will have gain errors that track to better than ±5ppm/°C.

RTD EXCITATION

The Resistance Temperature Detector (RTD) is a circuit element whose resistance is characterized by a positive temperature coefficient. A measurement of resistance indicates the measured temperature. Unfortunately, the resistance of the wires leading to the RTD often adds error to this measurement. The 4-wire ohms measurement overcomes this problem. This method uses two wires to bring an excitation current to the RTD and two additional wires to tap off the resulting RTD voltage. If these additional two wires go to a high input impedance measurement circuit, the effect of their resistance is negligible. Therefore, they transmit the true RTD voltage.

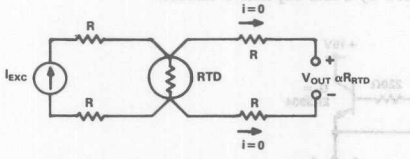

Figure 18. 4-Wire Ohms Measurement

A practical consideration when using the 4-wire ohms technique with an RTD is the self-heating effect that the excitation current has on the temperature of the RTD. The designer must choose the smallest practical excitation current that still gives the desired resolution. RTD manufactures usually specify the self-heating effect of each of their models or types of RTDs.

Figure 19 shows an AD588 providing the precision excitation current for a 100Ω RTD. The small excitation current of 1mA dissipates a mere 0.1mW of power in the RTD.

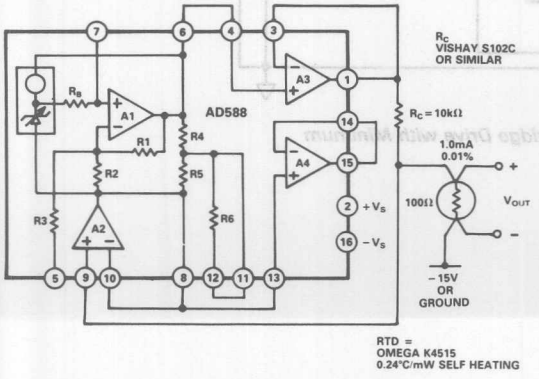

Figure 19. Precision Current Source for RTD

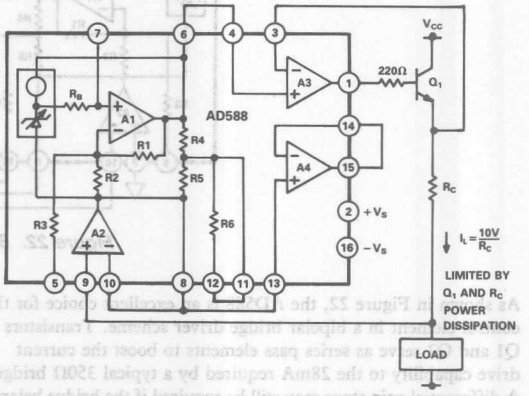
BOOSTED PRECISION CURRENT SOURCE

In the RTD current-source application the load current is limited to ±10mA by the output drive capability of amplifier A3. In the event that more drive current is needed, a series pass transistor can be inserted inside the feedback loop to provide higher current. Accuracy and drift performance are unaffected by the pass transistor.



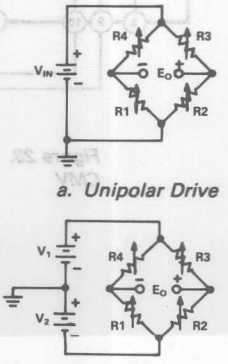


Figure 20. Boosted Precision Current Source

BRIDGE DRIVER CIRCUITS

The Wheatstone bridge is a common transducer. In its simplest form, a bridge consists of 4 two terminal elements connected to form a quadrilateral, a source of excitation connected along one of the diagonals and a detector comprising the other diagonal. Figure 21a shows a simple bridge driven from a unipolar excitation supply. E_O, a differential voltage, is proportional to the deviation of the element from the initial bridge values. Unfortunately, this bridge output voltage is riding on a common-mode voltage equal to approximately $V_{IN}/2$. Further processing of this signal may necessarily be limited to high common-mode rejection techniques such as instrumentation or isolation amplifiers.

Figure 21b shows the same bridge transducer, but this time it is driven from pair of bipolar supplies. This configuration ideally eliminates the common-mode voltage and relaxes the restrictions on any processing elements that follow.

a. Unipolar Drive

b. Bipolar Drive

Figure 21. Bridge Transducer Excitation

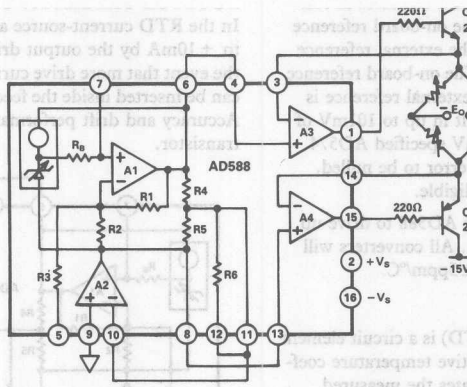

Figure 22. Bipolar Bridge Drive

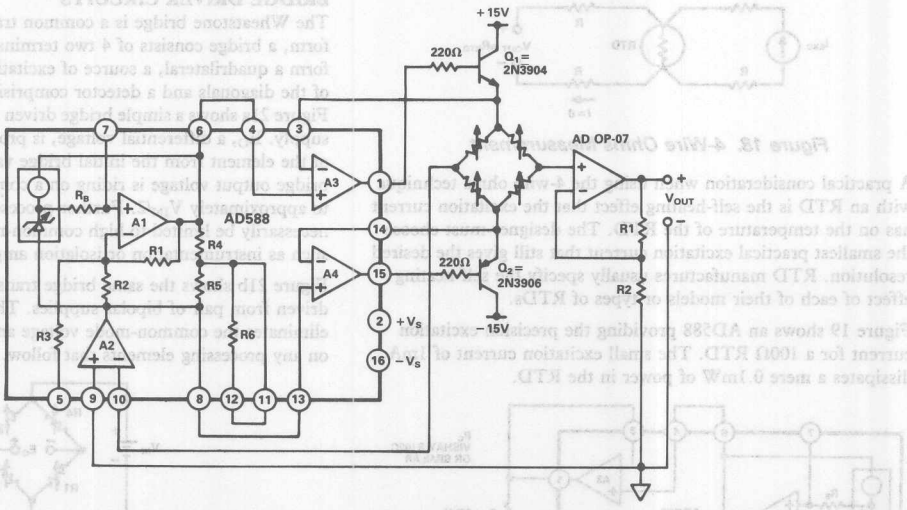
As shown in Figure 22, the AD588 is an excellent choice for the control element in a bipolar bridge driver scheme. Transistors Q1 and Q2 serve as series pass elements to boost the current drive capability to the 28mA required by a typical 350Ω bridge. A differential gain stage may still be required if the bridge balance is not perfect. Such gain stages can be expensive.

Additional common-mode voltage reduction is realized by using the circuit illustrated in Figure 23. A1, the ground sense amplifier, servo's the supplies on the bridge to maintain a virtual ground at one center tap. The voltage which appears on the opposite center tap is now single-ended (referred to ground) and can be amplified by a less expensive circuit.



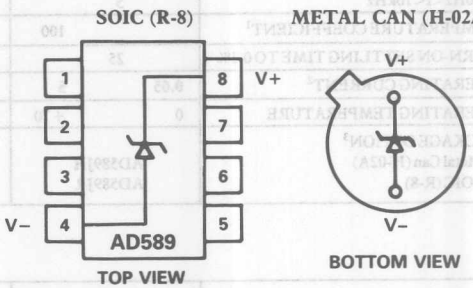


Figure 23. Floating Bipolar Bridge Drive with Minimum CMV

AD589

FEATURES

- Superior Replacement for Other 1.2V References
- Wide Operating Range: 50μA to 5mA
- Low Power: 60μW Total P_D at 50μA
- Low Temperature Coefficient:
  - 10ppm/°C max, 0 to +70°C (AD589M)
  - 25ppm/°C max, –55°C to +125°C (AD589U)
- Two-Terminal "Zener" Operation
- Low Output Impedance: 0.6Ω
- No Frequency Compensation Required
- Low Cost
- MIL-STD-883 Compliant Versions Available

FUNCTIONAL BLOCK DIAGRAMS

PRODUCT DESCRIPTION

The AD589 is a two-terminal, low cost, temperature compensated bandgap voltage reference which provides a fixed 1.23V output voltage for input currents between 50μA and 5.0mA.

The high stability of the AD589 is primarily dependent upon the matching and thermal tracking of the on-chip components. Analog Devices' precision bipolar processing and thin-film technology combine to provide excellent performance at low cost.

Additionally, the active circuit produces an output impedance ten times lower than typical low-TC zener diodes. This feature allows operation with no external components required to maintain full accuracy under changing load conditions.

The AD589 is available in seven versions. The AD589J, K, L and M grades are specified for 0 to +70°C operation, while the S, T and U grades are rated for the full –55°C to +125°C temperature range. All grades are available in a metal can (H-02A) package. The AD589J is also available in an 8-pin SOIC package.

PRODUCT HIGHLIGHTS

1. The AD589 is a two-terminal device which delivers a a constant reference voltage for a wide range of input current.
2. Output impedance of 0.6Ω and temperature coefficients as low as 10ppm/°C insure stable output voltage over a wide range of operating conditions.
3. The AD589 can be operated as a positive or negative reference. "Floating" operation is also possible.
4. The AD589 will operate with total current as low as 50μA (60μW total power dissipation), ideal for battery powered instrument applications.
5. The AD589 is an exact replacement for other 1.2V references, offering superior temperature performance and reduced sensitivity to capacitive loading.
6. The AD589 is available in versions compliant with MIL-STD-883. Refer to the Analog Devices Military Products Databook or current AD589/883B data sheet for detailed specifications.

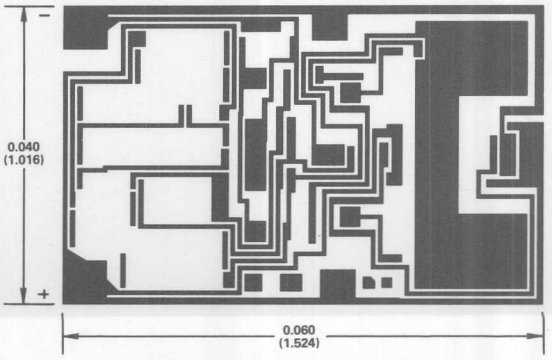
NOTES
[1]See following page for explanation of temperature coefficient measurement method.
[2]Optimum performance is obtained at currents below 500μA. For current operation below 200μA, stray shunt capacitances should be limited to 20pF or increased to 1μF. If strays can not be avoided, operation at 500μA and a shunt capacitor of at least 1000pF are recommended.
[3]H = Hermetic Metal Can; R = SOIC. For outline information see Package Information section.

Specifications shown in boldface are tested on all production units at final electrical test.



Specifications subject to change without notice.

ABSOLUTE MAXIMUM RATINGS

Current 10mA
Reverse Current 10mA
Power Dissipation[1] 125mW
Storage Temperature Range . . . . . –65°C to +175°C
Operating Junction Temperature Range . –55°C to +150°C
Lead Temperature (Soldering, 10sec) . . . . . +300°C

NOTE
[1]Absolute maximum power dissipation is limited by maximum current through the device. Maximum rating at elevated temperatures must be computed assuming $T_J \leq 150°C$, and $\theta_{JA} = 400 = C/W$.

AD589 CHIP DIMENSIONS AND PAD LAYOUT

THE AD589 IS AVAILABLE IN CHIP FORM WITH FULLY TESTED AND GUARANTEED SPECIFICATIONS. CONSULT FACTORY FOR AVAILABLE GRADES AND PRICING.

VOLTAGE VARIATION vs. TEMPERATURE

Some confusion exists in the area of defining and specifying reference voltage error over temperature. Historically, references have been characterized using a maximum deviation per degree Centigrade; i.e., 10ppm/°C. However, because of nonlinearities in temperature characteristics, which originated in standard zener references (such as "S" type characteristics) most manufacturers have begun to use a maximum limit error band approach to specify devices. This technique involves measurement of the output at 3, 5 or more different temperatures to guarantee that the output voltage will fall within the given error band. The temperature characteristic of the AD589 consistently follows the curve shown in Figure 1. Three-point measurement guarantees the error band over the specified temperature range. The temperature coefficients specified on page 2 represent the slopes of the diagonals of the error band from +25°C to T_{min} and +25°C to T_{max}.

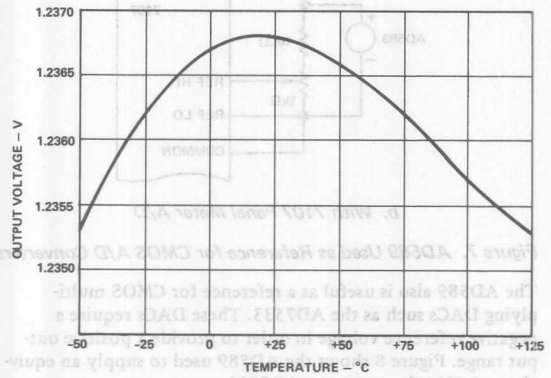


Figure 1. Typical AD589 Temperature Characteristics

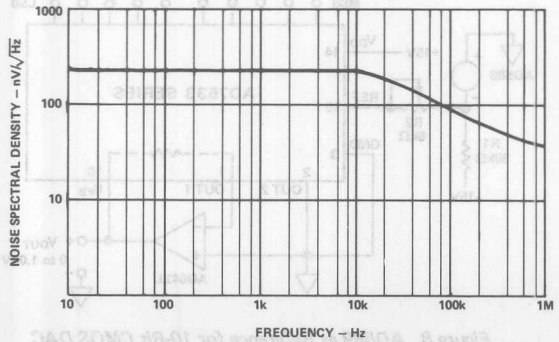

Figure 2. Noise Spectral Density

DYNAMIC PERFORMANCE

Many low power instrument manufacturers are becoming increasingly concerned with the turn-on characteristics of the components being used in their systems. Fast turn-on components often enable the end user to keep power off when not needed, and yet respond quickly when the power is turned on for operation. Figure 3 displays the turn-on characteristic of the AD589. This characteristic is generated from cold-start operation and represents the true turn-on waveform after an extended period with the supplies off. The figure shows both the coarse and fine transient characteristics of the device; the total settling time to within ±1 millivolt is about 25μs, and there is no long thermal tail appearing after that point.

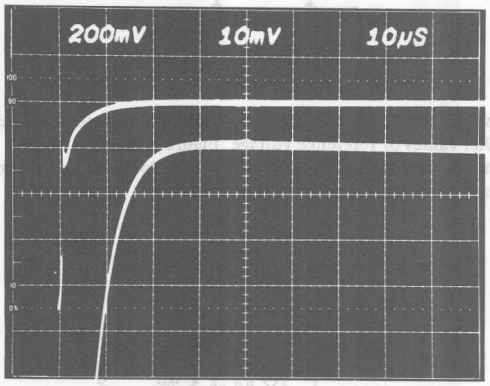

Figure 3. Output Settling Characteristics

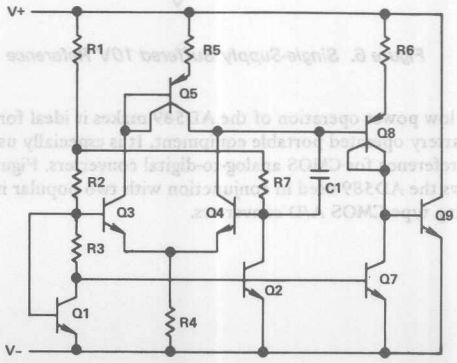

Figure 4. Schematic Diagram

6

The AD589 functions as a two-terminal shunt-type regulator. It provides a constant 1.23V output for a wide range of input current from 50μA to 5mA. Figure 5 shows the simplest configuration for an output voltage of 1.2V or less. Note that no frequency compensation is required. If additional filtering is desired for ultra low noise applications, minimum recommended capacitance is 1000pF.

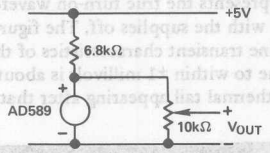

Figure 5. Basic Configuration for 1.2V or Less

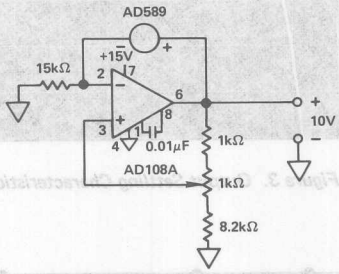
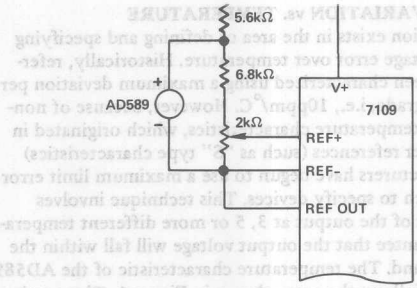
The AD589 can also be used as a building block to generate other values of reference voltage. Figure 6 shows a circuit which produces a buffered 10V output. Total supply current for this circuit is approximately 2mA.





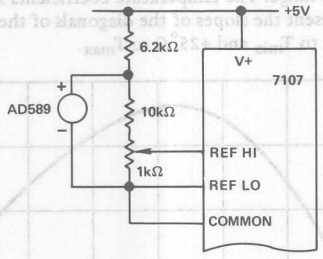


Figure 6. Single-Supply Buffered 10V Reference

The low power operation of the AD589 makes it ideal for use in battery operated portable equipment. It is especially useful as a reference for CMOS analog-to-digital converters. Figure 7 shows the AD589 used in conjunction with two popular integrating type CMOS A/D converters.

a. With 7109 12-Bit Binary A/D

b. With 7107 Panel Meter A/D

Figure 7. AD589 Used as Reference for CMOS A/D Converters

The AD589 also is useful as a reference for CMOS multiplying DACs such as the AD7533. These DACs require a negative reference voltage in order to provide a positive output range. Figure 8 shows the AD589 used to supply an equivalent −1.0V reference to an AD7533.

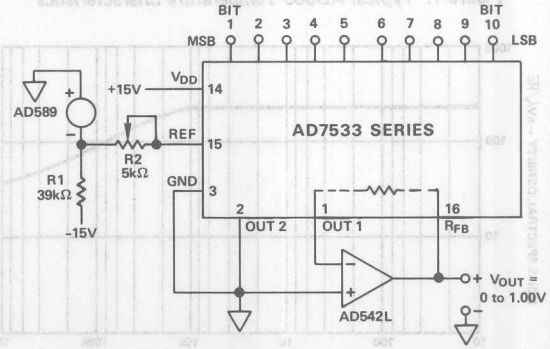

Figure 8. AD589 as Reference for 10-Bit CMOS DAC

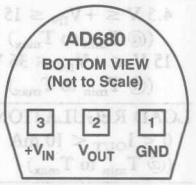
Low Power, Low Cost 2.5 V Reference

AD680*

FEATURES



Low Quiescent Current: 250 μA max
Laser Trimmed to High Accuracy:
2.5 V ±5 mV max (AN Grade)
Trimmed Temperature Coefficient:
20 ppm/°C max (AN Grade)
Low Noise: 8 μV p–p from 0.1 to 10 Hz
250 nV/√Hz Wideband
Temperature Output Pin (N, R Packages)
Available in Three Package Styles:
8-Pin Plastic DIP, 8-Pin SOIC and 3-Pin TO-92

CONNECTION DIAGRAMS

NC = NO CONNECT

*TP DENOTES FACTORY TEST POINT. NO CONNECTIONS SHOULD BE MADE TO THESE PINS.

PRODUCT DESCRIPTION

The AD680 is a bandgap voltage reference which provides a fixed 2.5 V output from inputs between 4.5 V and 36 V. The architecture of the AD680 enables the reference to be operated at a very low quiescent current while still realizing excellent dc characteristics and noise performance. Trimming of the high stability thin-film resistors is performed for initial accuracy and temperature coefficient, resulting in low errors over temperature.

The precision dc characteristics of the AD680 make it ideal for use as a reference for D/A converters which require an external precision reference. The device is also ideal for A/D converters and, in general, can offer better performance than the standard on-chip references.

Based upon the low quiescent current of the AD680, which rivals that of many incomplete two-terminal references, the AD680 is recommended for low power applications such as hand-held battery equipment.

A temperature output pin is provided on the 8-pin package versions of the AD680. The temperature output pin provides an output voltage that varies linearly with temperature and allows the AD680 to be configured as a temperature transducer while providing a stable 2.5 V output.

The AD680 is available in four grades. The AD680AN is specified for operation from −40°C to +85°C, while the AD680JN is specified for 0°C to +70°C operation. Both the AD680AN and AD680JN are available in 8-pin plastic DIP packages. The AD680JR is specified for 0°C to +70°C operation and is available in an 8-pin Small Outline IC (SOIC) package. The AD680JT is specified for 0°C to +70°C operation and is available in a 3-pin TO-92 package.

***Protected by Patent Nos. 4,902,959; 4,250,445 and 4,857,862.**

PRODUCT HIGHLIGHTS

1. The AD680 bandgap reference operates on a very low quiescent current which rivals that of many two-terminal references. This makes the complete, higher accuracy AD680 ideal for use in power sensitive applications.
2. Laser trimming of both initial accuracy and temperature coefficients results in low errors over temperature without the use of external components. The AD680AN has a maximum variation of 6.25 mV between −40°C and +85°C.
3. The AD680 noise is low, typically 8 μV p–p from 0.1 to 10 Hz. Spectral density is also low, typically 250 nV/√Hz.
4. The temperature output pin on the 8-pin package versions enables the AD680 to be configured as a temperature transducer.
5. Plastic DIP packaging provides machine insertability, while SOIC packaging provides surface mount capability. TO-92 packaging offers a cost effective alternative to two-terminal references, offering a complete solution in the same package in which two-terminal references are usually found.

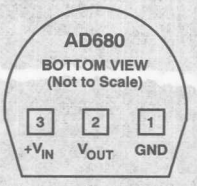

Figure 1. Connection Diagrams

THEORY OF OPERATION

Bandgap references are the high performance solution for low supply voltage operation. A typical precision bandgap will consist of a reference core and buffer amplifier. Based on a new, patented bandgap reference design (Figure 2), the AD680 merges the amplifier and the core bandgap function to produce a compact, complete precision reference. Central to the device is a high gain amplifier with an intentionally large Proportional To Absolute Temperature (PTAT) input offset. This offset is controlled by the area ratio of the amplifier input pair, Q1 and Q2, and is developed across resistor R1. Transistor Q12's base emitter voltage has a Complementary To Absolute Temperature (CTAT) characteristic. Resistor R2 and the parallel combination of R3 and R4 "multiply" the PTAT voltage across R1. Trimming resistors R3 and R4 to the proper ratio produces a temperature invariant 2.5 V at the output. The result is an accurate, stable output voltage accomplished with a minimum number of components.

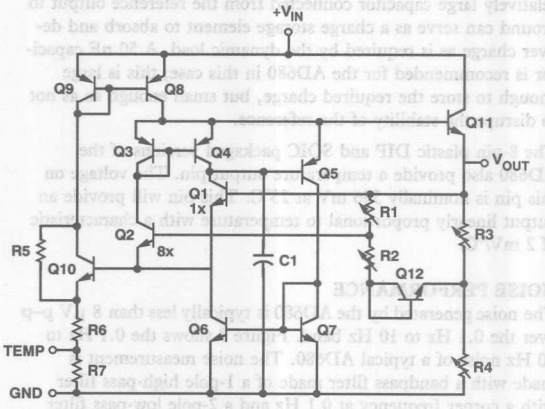

Figure 2. AD680 Schematic Diagram

An additional feature with this approach is the ability to minimize the noise while maintaining very low overall power dissipation for the entire circuit. Frequently it is difficult to independently control the dominant noise sources for bandgap references: bandgap transistor noise and resistor thermal noise. By properly choosing the operating currents of Q1 and Q2 and separately sizing R1, low wideband noise is realized while maintaining 1 mW typical power dissipation.

ORDERING GUIDE

APPLYING THE AD680

The AD680 is simple to use in virtually all precision reference applications. When power is applied to $+V_{IN}$ and the GND pin is tied to ground, V_{OUT} provides a +2.5 V output. The AD680 typically requires less than 250 μA of current when operating from a supply of +4.5 V to +36 V.

To operate the AD680, the $+V_{IN}$ pin must be bypassed to the GND pin with a 0.1 μF capacitor tied as close to the AD680 as possible. Although the ground current for the AD680 is small (typically 195 μA), a direct connection should be made between the AD680 GND pin and the system ground plane.

Reference outputs are frequently required to handle fast transients caused by input switching networks, as are commonly found in ADCs and measurement instrumentation equipment. Many of the dynamic problems associated with this situation can be minimized with a few simple techniques. Using a series resistor between the reference output and the load will tend to "decouple" the reference output from the transient source. Or a relatively large capacitor connected from the reference output to ground can serve as a charge storage element to absorb and deliver charge as is required by the dynamic load. A 50 nF capacitor is recommended for the AD680 in this case; this is large enough to store the required charge, but small enough so as not to disrupt the stability of the reference.

The 8-pin plastic DIP and SOIC packaged versions of the AD680 also provide a temperature output pin. The voltage on this pin is nominally 596 mV at 25°C. This pin will provide an output linearly proportional to temperature with a characteristic of 2 mV/°C.

NOISE PERFORMANCE

The noise generated by the AD680 is typically less than 8 μV p–p over the 0.1 Hz to 10 Hz band. Figure 3 shows the 0.1 Hz to 10 Hz noise of a typical AD680. The noise measurement is made with a bandpass filter made of a 1-pole high-pass filter with a corner frequency at 0.1 Hz and a 2-pole low-pass filter with a corner frequency at 12.6 Hz to create a filter with a 9.922 Hz bandwidth.

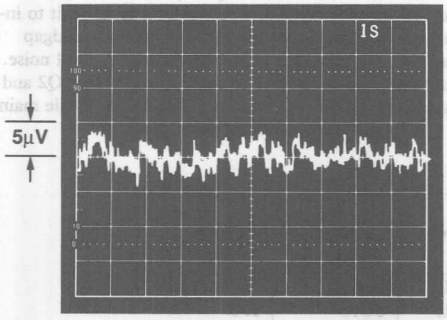

Figure 3. 0.1 Hz to 10 Hz Noise

Noise in a 300 kHz bandwidth is approximately 800 μV p–p. Figure 4 shows the broadband noise of a typical AD680.

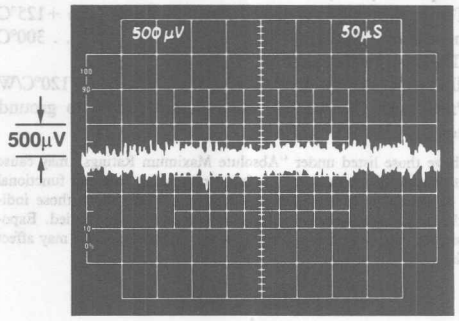

Figure 4. Broadband Noise at 300 kHz

TURN-ON TIME

Upon application of power (cold start), the time required for the output voltage to reach its final value within a specified error band is defined as the turn-on settling time. Two components normally associated with this are: the time for the active circuits to settle, and the time for the thermal gradients on the chip to stabilize. Figure 5 shows the turn-on settling time of the AD680 to be about 20 μs to 0.025% of its final value.

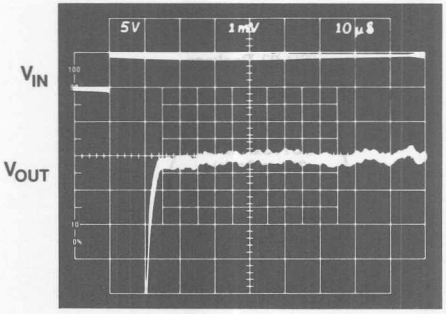

Figure 5. Turn-On Settling Time

The AD680 thermal settling characteristic benefits from its compact design. Once initial turn-on is achieved, the output linearly approaches its final value; the output is typically within 0.01% of its final value after 25 ms.

DYNAMIC PERFORMANCE

The output stage of the amplifier is designed to provide the AD680 with static and dynamic load regulation superior to less complete references.

Figure 6 displays the characteristics of the AD680 output amplifier driving a 0 to 10 mA load. Longer settling times will result if the reference is forced to sink any transient current.

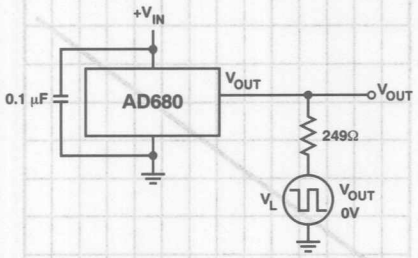

Figure 6a. Transient Load Test Circuit

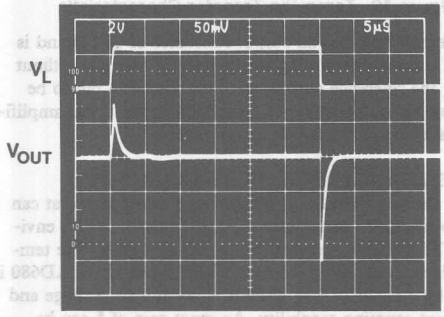

Figure 6b. Large-Scale Transient Response

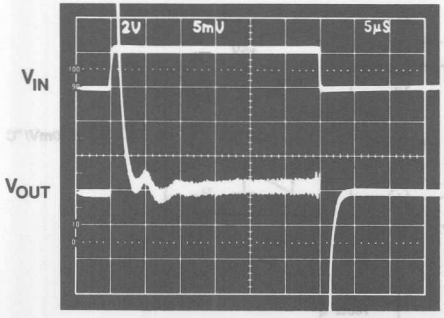

Figure 6c. Fine Scale Settling for Transient Load

In some applications, a varying load may be both resistive and capacitive in nature, or the load may be connected to the AD680 by a long capacitive cable.

TEMPERATURE PERFORMANCE

The AD680 is designed for reference applications where temperature performance is important. Extensive temperature testing and characterization ensures that the device's performance is maintained over the specified temperature range.

Some confusion exists in the area of defining and specifying reference voltage error over temperature. Historically, references have been characterized using a maximum deviation per degree centigrade, i.e., ppm/°C. However, because of nonlinearities in temperature characteristics which originated in standard Zener references (such as "S" type characteristics), most manufacturers now use a maximum limit error band approach to specify devices. This technique involves the measurement of the output at three or more different temperatures to specify an output voltage error band.

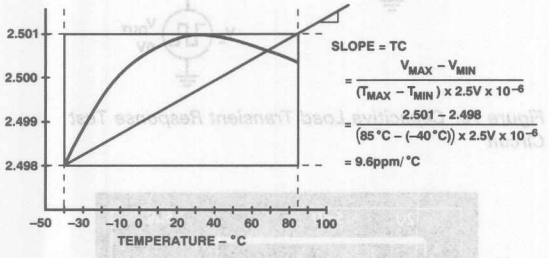

Figure 9. Typical AD680AN Temperature Drift

Figure 9 shows a typical output voltage drift for the AD680AN and illustrates the test methodology. The box in Figure 9 is bounded on the sides by the operating temperature extremes, and on the top and bottom by the maximum and minimum output voltages measured over the operating temperature range.

The maximum height of the box for the appropriate temperature range and device grade is shown in Table I. Duplication of these results requires a combination of high accuracy and stable temperature control in a test system. Evaluation of the AD680 will produce a curve similar to that in Figure 9, but output readings may vary depending upon the test equipment utilized.

Table I. Maximum Output Change in mV

Device Grade	Maximum Output Change (mV) 0°C to +70°C	−40°C to +85°C
AD680JN/JR	4.375	—
AD680JT	5.250	—
AD680AN	—	6.250

TEMPERATURE OUTPUT PIN

The 8-pin packaged versions of the AD680 provide a temperature output pin on Pin 3 of each device. The output of Pin 3 (TEMP) is a voltage that varies linearly with temperature. V_{TEMP} at 25°C is 596 mV, and the temperature coefficient is 2 mV/°C. Figure 10 shows the output of this pin over temperature.

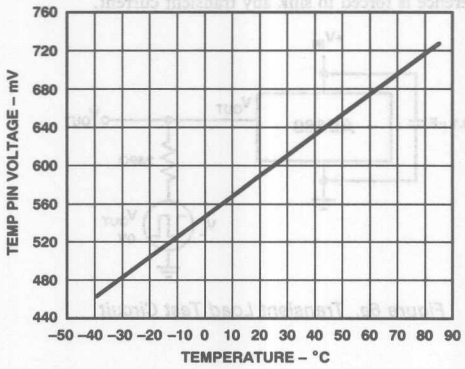

Figure 10. Temp Pin Transfer Characteristic

The temperature pin has an output resistance of 12 kΩ and is capable of sinking or sourcing currents of up to 5 μA without disturbing the reference output, enabling the temp pin to be buffered by any of a number of inexpensive operational amplifiers that have bias currents below this value.

DIFFERENTIAL TEMPERATURE TRANSDUCER

Figure 11 shows a differential temperature transducer that can be used to measure temperature changes in the AD680's environment. This circuit operates from a +5 V supply. The temperature dependent voltage from the TEMP pin of the AD680 is amplified by a factor of 5 to provide wider full-scale range and more current sourcing capability. An exact gain of 5 can be achieved by adjusting the trim potentiometer until the output varies by 10 mV/°C. To minimize resistance changes with temperature, resistors with low temperature coefficients, such as metal film resistors, should be used.

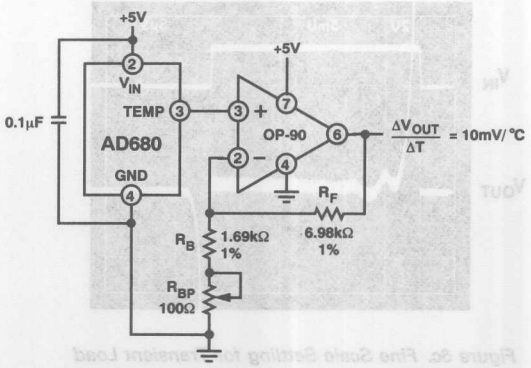

Figure 11. Differential Temperature Transducer

LOW POWER, LOW VOLTAGE REFERENCE FOR DATA CONVERTERS

The AD680 has a number of features that make it ideally suited for use with A/D and D/A converters. The low supply voltage required makes it possible to use the AD680 with today's converters that run on 5 V supplies without having to add a higher supply voltage for the reference. The low quiescent current (195 μA), combined with the completeness and accuracy of the AD680 make it ideal for low power applications such as handheld, battery operated meters.

One such ADC that the AD680 is well suited for is the AD7701. Figure 12a shows the AD680 used as the reference for this converter. The AD7701 is a 16-bit A/D converter with on-chip digital filtering intended for the measurement of wide dynamic range, low frequency signals such as those representing chemical, physical or biological processes. It contains a charge balancing (sigma-delta) ADC, calibration microcontroller with on-chip static RAM, a clock oscillator and a serial communications port.

This entire circuit runs on ±5 V supplies. The power dissipation of the AD7701 is typically 25 mW and, when combined with the power dissipation of the AD680 (1 mW), the entire circuit consumes just 26 mW of power.

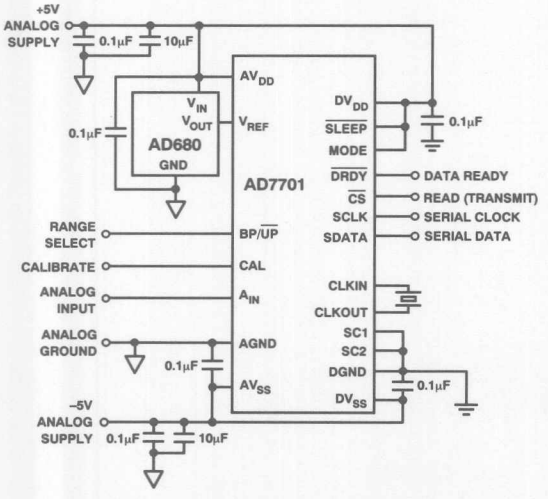

Figure 12a. Low Power, Low Voltage Supply Reference for the AD7701 16-Bit A/D Converter

Figure 12b shows the AD680 connected to the AD773 high speed 8-bit ADC. The low pass filter shown minimizes the AD680's wideband noise.

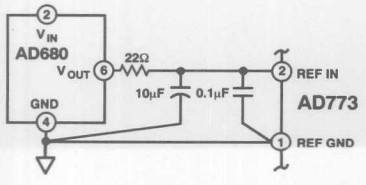

Figure 12b. AD680 to AD773 Connection

The AD773's high impedance reference input allows direct connection to the AD680. Unlike the resistor ladder requirements of a flash converter the AD773's single pin, high impedance input can be driven from one low cost, low power reference. The high impedance input allows multiple AD773's to be driven from one AD680 thus minimizing drift errors.

+4.5 V REFERENCE FROM A +5 V SUPPLY

The AD680 can be used to provide a low power, +4.5 V reference as shown in Figure 13. In addition to the AD680, the circuit uses a low power op amp and a transistor in a feedback configuration that provides a regulated +4.5 V output for a power supply voltage as low as +4.7 V. The high quality tantalum 10 μF capacitor (C1) in parallel with the ceramic 0.1 μF capacitor (C2) and the 3.9 Ω resistor (R5) ensure a low output impedance up to around 50 MHz.

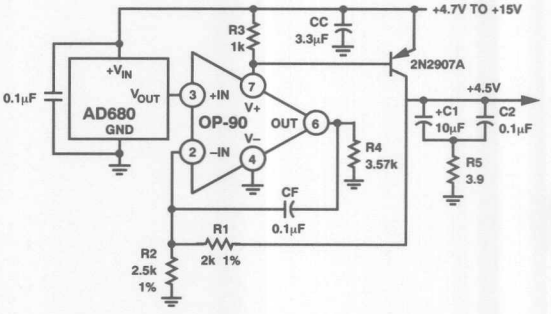

Figure 13. +4.5 V Reference Running from a Single +5 V Supply

VOLTAGE REGULATOR FOR PORTABLE EQUIPMENT

The AD680 is ideal for providing a stable, low cost and low power reference voltage in portable equipment power supplies. Figure 14 shows how the AD680 can be used in a voltage regulator that not only has low output noise (as compared to a switchmode design) and low power, but also a very fast recovery after current surges. Some precaution should be taken in the selection of the output capacitors. Too high an ESR (effective series resistance) could endanger the stability of the circuit. A solid tantalum capacitor, 16 V or higher, and an aluminum electrolytic capacitor, 10 V or higher, are recommended for C1 and C2, respectively. Also, the path from the ground side of C1 and C2 to the ground side of R1 should be kept as short as possible.

AD688*

FEATURES

±10 V Tracking Outputs
Kelvin Connections
Low Tracking Error – 1.5 mV
Low Initial Error – 2.0 mV
Low Drift – 1.5 ppm/°C
Low Noise – 6 μV p–p
Flexible Output Force and Sense Terminals
High Impedance Ground Sense
Machine Insertable DIP Packaging
MIL-STD-883 Compliant Versions Available

FUNCTIONAL BLOCK DIAGRAM

PRODUCT DESCRIPTION

The AD688 is a high precision ±10 V tracking reference. Low tracking error, low initial error and low temperature drift give the AD688 reference absolute ±10 V accuracy performance previously unavailable in monolithic form. The AD688 uses a proprietary ion-implanted buried Zener diode, and laser-wafer-drift-trimming of high stability thin-film resistors to provide outstanding performance at low cost.

The AD688 includes the basic reference cell and three additional amplifiers. The amplifiers are laser-trimmed for low offset and low drift and maintain the accuracy of the reference. The amplifiers are configured to allow Kelvin connections to the load and/or boosters for driving long lines or high current loads, delivering the full accuracy of the AD688 where it is required in the application circuit.

The low initial error allows the AD688 to be used as a system reference in precision measurement applications requiring 12-bit absolute accuracy. In such systems, the AD688 can provide a known voltage for system calibration and the cost of periodic recalibration can therefore be eliminated. Furthermore, the mechanical instability of a trimming potentiometer and the potential for improper calibration can be eliminated by using the AD688 and calibration software.

The AD688 is available in three versions. The AD688AQ and BQ grades are packaged in 16-pin cerdip (0.3″) packages and are specified for operation from −40°C to +85°C. The AD688SQ grade is specified for operation from −55°C to +125°C.

***Protected by Patent Number 4,644,253.**

PRODUCT HIGHLIGHTS

1. The AD688 offers precision tracking ±10 V Kelvin output connections with no external components. Tracking error is less than 1.5 mV and a fine-trim is available for applications requiring exact symmetry between the +10 V and −10 V outputs.
2. The AD688 offers 12-bit absolute accuracy without any user adjustments. Optional fine-trim connections are provided for applications requiring higher precision. The fine-trimming does not alter the operating conditions of the Zener or the buffer amplifiers and thus does not increase the temperature drift.
3. Output noise of the AD688 is low – typically 6 μV p–p. A pin is provided for broadband noise filtering using an external capacitor.
4. The AD688 is available in versions compliant with MIL-STD-883. Refer to the Analog Devices Military Products Databook or current AD688/883B data sheet for detailed specifications.

PIN CONFIGURATION

NC = NO CONNECT

NC PINS ARE USED AS TEST POINTS BY THE FACTORY. TO ENSURE PROPER OPERATION, DO NOT CONNECT ANYTHING TO THESE PINS.

THEORY OF OPERATION

The AD688 consists of a buried Zener diode reference, amplifiers and associated thin-film resistors as shown in the block diagram of Figure 1. The temperature compensation circuitry provides the device with a temperature coefficient of 1.5 ppm/°C or less.

Amplifier A1 performs several functions. A1 primarily acts to amplify the Zener voltage to the required 20 volts. In addition, A1 also provides for external adjustment of the 20 V output through Pin 5, the GAIN ADJUST. Using the bias compensation resistor between the Zener output and the noninverting input to A1, a capacitor can be added at the NOISE REDUCTION pin (Pin 7) to form a low pass filter and reduce the noise contribution of the Zener to the circuit. Two matched 12 kΩ nominal thin-film resistors (R4 and R5) divide the 20 V output in half.

Ground sensing for the circuit is provided by Amplifier A2. The noninverting input (Pin 9) senses the system ground and forces the midpoint of resistors R4 and R5 to be a virtual ground. Pin 12 (BALANCE ADJUST) can be used for fine adjustment of this midpoint transfer.

Amplifiers A3 and A4 are internally compensated and are used to buffer the voltages at Pins 6 and 8 as well as to provide a full Kelvin output. Thus, the AD688 has a full Kelvin capability by providing the means to sense a system ground and provide forced and sensed outputs referenced to that ground.

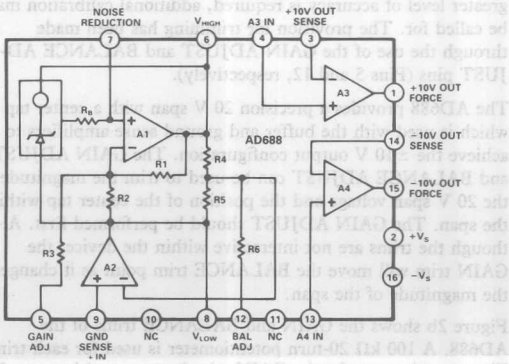

Figure 1. AD688 Functional Block Diagram

APPLYING THE AD688

The AD688 can be configured to provide ±10 V reference outputs as shown in Figure 2a. The architecture of the AD688 provides ground sense and uncommitted output buffer amplifiers which offer the user a great deal of functional flexibility. The AD688 is specified and tested in the configuration shown in Figure 2a. The user may choose to take advantage of other configuration options available with the AD688; however performance in these configurations is not guaranteed to meet the stringent data sheet specifications.

Unbuffered outputs are available at Pins 6 and 8. Loading of these unbuffered outputs will impair circuit performance.

Amplifiers A3 and A4 can be used interchangeably. However, the AD688 is tested (and the specifications are guaranteed) with the amplifiers connected as indicated in Figure 2a. When either A3 or A4 is unused, its output force and sense pins should be connected and the input tied to ground.

Two outputs of the same voltage polarity may be obtained by connecting both A3 and A4 to the appropriate unbuffered output on Pin 6 or 8. Performance in these dual output configurations will typically meet data sheet specifications.

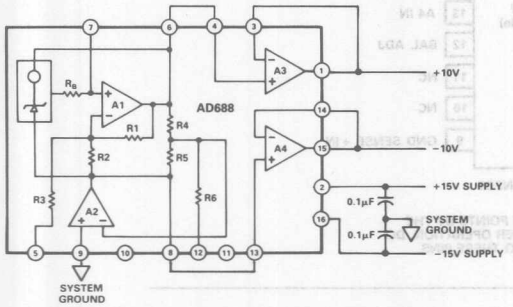

Figure 2a. +10 V and −10 V Outputs

CALIBRATION

Generally, the AD688 will meet the requirements of a precision system without additional adjustment. Initial output voltage error of 2 mV and output noise specs of 6 μV p–p allow for accuracies of 12–16 bits. However, in applications where an even greater level of accuracy is required, additional calibration may be called for. The provision for trimming has been made through the use of the GAIN ADJUST and BALANCE ADJUST pins (Pins 5 and 12, respectively).

The AD688 provides a precision 20 V span with a center tap which is used with the buffer and ground sense amplifiers to achieve the ±10 V output configuration. The GAIN ADJUST and BALANCE ADJUST can be used to trim the magnitude of the 20 V span voltage and the position of the center tap within the span. The GAIN ADJUST should be performed first. Although the trims are not interactive within the device, the GAIN trim will move the BALANCE trim point as it changes the magnitude of the span.

Figure 2b shows the GAIN and BALANCE trims of the AD688. A 100 kΩ 20-turn potentiometer is used for each trim. The potentiometer for the GAIN trim is connected between Pins 6 (V_{HIGH}) and 8 (V_{LOW}) with the wiper connected to Pin 5 (GAIN ADJ). The potentiometer is adjusted to produce exactly 20 V between Pins 1 and 15, the amplifier outputs. The BALANCE potentiometer, also connected between Pins 6 and 8 with the wiper to Pin 12 (BAL ADJ), is then adjusted to center the span from +10 V to −10 V.

Input impedance on both the GAIN ADJUST and the BALANCE ADJUST pins is approximately 150 kΩ. The GAIN ADJUST trim network effectively attenuates the 20 V across the trim potentiometer by a factor of about 1150 to provide a trim range of −5.8 mV to +12.0 mV with a resolution of approximately 900 μV/turn (20 turn potentiometer). The BALANCE ADJUST trim network attenuates the trim voltage by a factor of about 1250, providing a trim range of ±8 mV with a resolution of 800 μV/turn.

Trimming the AD688 introduces no additional errors over temperature, so precision potentiometers are not required.

In cases when BALANCE ADJUST is not necessary, Pin 12 should be left floating. If GAIN ADJUST is not required, Pin 5 should also be left floating.

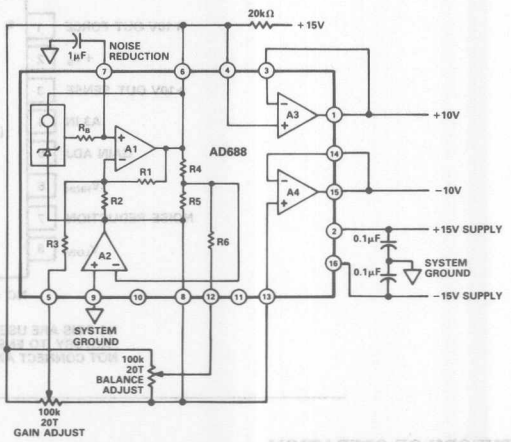

Figure 2b. Gain and Balance Adjust with Noise Reduction

NOISE PERFORMANCE AND REDUCTION

The noise generated by the AD688 is typically less than 6 μV p–p over the 0.1 Hz to 10 Hz band. Noise in a 1 MHz bandwidth is approximately 840 μV p–p. The dominant source of this noise is the buried Zener which contributes approximately 140 nV/$\sqrt{\text{Hz}}$. In comparison, the op amp's contribution is negligible. Figure 3 shows the 0.1 Hz to 10 Hz noise of a typical AD688.

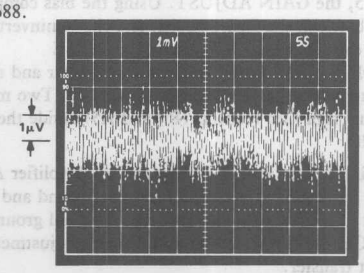

Figure 3. 0.1 Hz to 10 Hz Noise

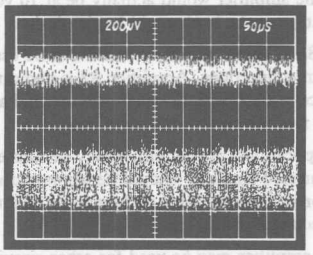
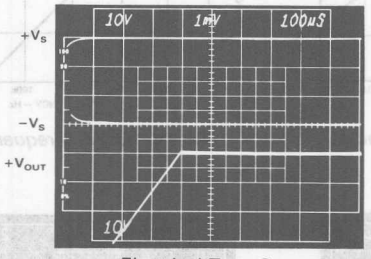
If further noise reduction is desired, an optional capacitor may be added between the NOISE REDUCTION pin and ground as shown in Figure 2b. This will form a low pass filter with the

5 kΩ R_B on the output of the Zener cell. A 1 μF capacitor will have a 3 dB point at 32 Hz and will reduce the high frequency noise (to 1 MHz) to about 250 μV p-p. Figure 4 shows the 1 MHz noise of a typical AD688 both with and without a 1 μF capacitor.





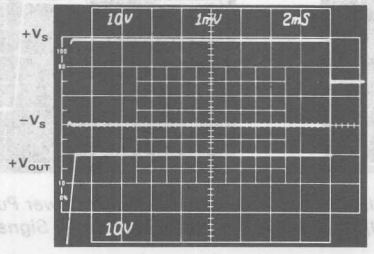


Figure 4. Effect of 1 μF Noise Reduction Capacitor on Broadband Noise

TURN-ON TIME

Upon application of power (cold start), the time required for the output voltage to reach its final value within a specified error is the turn-on settling time. Two components normally associated with this are: time for active circuits to settle and time for thermal gradients on the chip to stabilize. Figure 5 shows the turn-on characteristics of the AD688. It shows the settling time to be about 600 μs. Note the absence of any thermal tails when the horizontal scale is expanded to 2 ms/cm in Figure 5b.

a. Electrical Turn-On

b. Extended Time Scale

Figure 5. Turn-On Characteristics

Output turn-on time is modified when an external noise reduction capacitor is used. When present, this capacitor presents an additional load to the internal Zener diode's current source, resulting in a somewhat longer turn-on time. In the case of a 1 μF capacitor, the initial turn-on time is approximately 100 ms (see Figure 6).

When the NOISE REDUCTION feature is used, a 20 kΩ resistor between Pins 6 and 2 is required for proper startup.

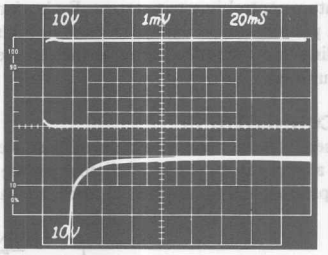

Figure 6. Turn-On With 1μF C_N

TEMPERATURE PERFORMANCE

The AD688 is designed for precision reference applications where temperature performance is critical. Extensive temperature testing ensures that the device's high level of performance is maintained over the operating temperature range.

Figure 7 shows the typical output voltage drift for the AD688SQ and illustrates the test methodology. The box in Figure 7 is bounded on the sides by the operating temperature extremes and on top and bottom by the maximum and minimum +10 V output error voltages measured over the operating temperature range. The slopes of the diagonals drawn for both the +10 V and −10 V outputs determine the performance grade of the device.

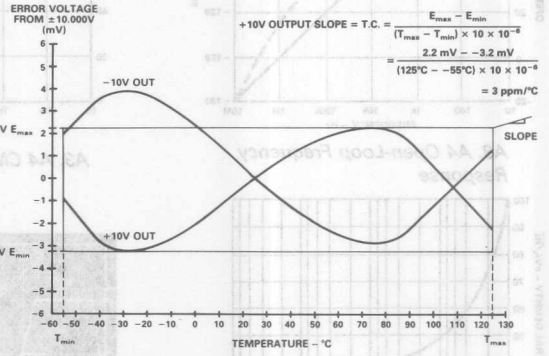

Figure 7. Typical AD688SQ Temperature Drift

Each AD688A and B grade unit is tested at −40°C, −25°C, 0°C, +25°C, +50°C, +70°C and +85°C. Each AD688S grade unit is tested at −55°C, −25°C, +25°C, +70°C and +125°C. This approach ensures that the variations of output voltage that occur as the temperature changes within the specified range will be contained within a box whose diagonal has a slope equal to the maximum specified drift. The position of the box on the vertical scale will change from device to device as initial error and the shape of the curve vary. Maximum height of the box for the appropriate temperature range is shown in Figure 8. Duplication

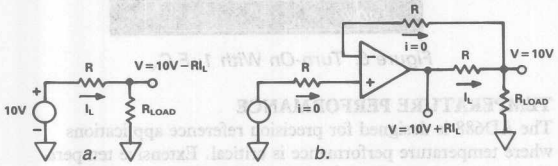
DEVICE GRADE	MAXIMUM OUTPUT CHANGE mV 0 TO +70°C	−40°C TO +85°C	−55°C TO +125°C
AD688AQ	1.40 (typ)	3.75	
AD688BQ	1.05	3.75	
AD688SQ			10.80

Figure 8. Maximum +10 V or −10 V Output Change

AD688 will produce curves similar to those in Figure 7, but output readings may vary depending on the test methods and equipment utilized.

KELVIN CONNECTIONS

Force and sense connections, also referred to as Kelvin connections, offer a convenient method of eliminating the effects of voltage drops in circuit wires. As seen in Figure 9a, the load



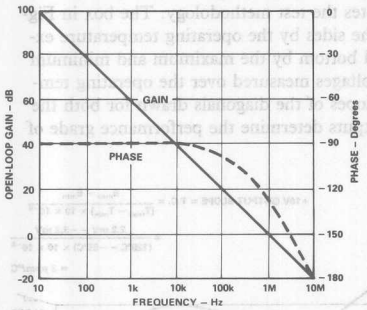


Figure 9. Advantage of Kelvin Connection

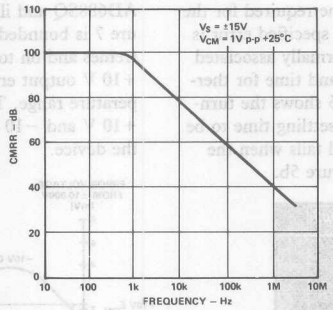
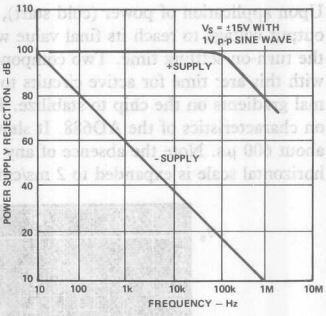
problem by including the wire resistance within the forcing loop of the amplifier and sensing the load voltage. The amplifier corrects for any errors in the load voltage. In the circuit shown, the output of the amplifier would actually be at 10 volts + V_{ERROR} and the voltage at the load would be the desired 10 volts.



The AD688 has three amplifiers which can be used to implement Kelvin connections. Amplifier A2 is dedicated to the ground force-sense function while uncommitted amplifiers A3 and A4 are free for other force-sense chores.

In some applications, one amplifier may be unused. In such cases, the unused amplifier should be connected as a unity-gain follower (force and sense pins tied together) and the input should be connected to ground.



An unused amplifier may be used for other circuit functions as well. The curves on this page show the typical performance of A3 and A4.

DYNAMIC PERFORMANCE

The output buffer amplifiers (A3 and A4) are designed to provide the AD688 with static and dynamic load regulation superior to less complete references.

Many A/D and D/A converters present transient current loads to the reference, and poor reference response can degrade the converter's performance.

Figure 10 displays the characteristic of the AD688 output amplifier driving a 0–to–10 mA load.

capacitive in nature, or be connected to the AD688 by a long capacitive cable. Figure 12 displays the output amplifier characteristics driving a 1,000 pF, 0–to–10 mA load.

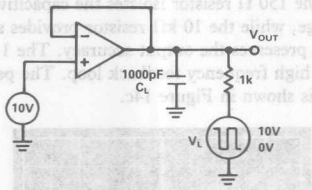

Figure 12a. Capacitive Load Transient Response Test Circuit

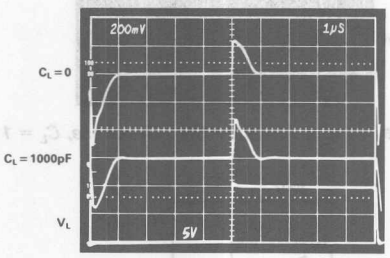

Figure 12b. Output Response with Capacitive Load

Figure 13 displays the crosstalk between output amplifiers. The top trace shows the output of A4, dc-coupled and offset by 10 volts, while the output of A3 is subjected to a 0–to–10 mA load current step. The transient at A4 settles in about 1 µs, and the load-induced offset is about 100 µV.

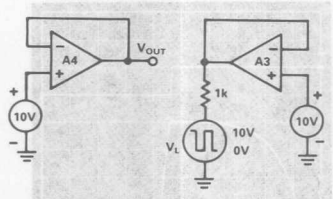

Figure 13a. Load Crosstalk Test Circuit

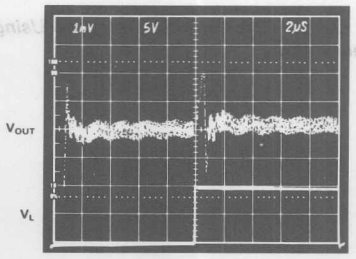

Figure 13b. Load Crosstalk

6

Attempts to drive a large capacitive load (in excess of 1,000 pF) may result in ringing or oscillation, as shown in the step response photo (Figure 14a). This is due to the additional pole formed by the load capacitance and the output impedance of the amplifier, which consumes phase margin. The recommended method of driving capacitive loads of this magnitude is shown in Figure 14b. The 150 Ω resistor isolates the capacitive load from the output stage, while the 10 kΩ resistor provides a dc feedback path and preserves the output accuracy. The 1 μF capacitor provides a high frequency feedback loop. The performance of this circuit is shown in Figure 14c.

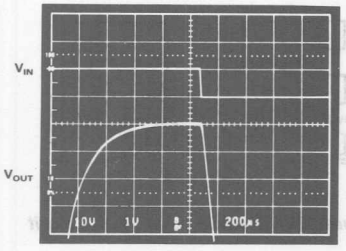

Figure 14c. Output Amplifier Step Response Using Figure 14b Compensation

BRIDGE DRIVER CIRCUIT

The Wheatstone bridge is a common transducer. In its simplest form, a bridge consists of 4 two-terminal elements connected to form a quadrilateral, a source of excitation connected along one of the diagonals and a detector comprising the other diagonal. In this unipolar drive configuration, the output voltage of the bridge is riding on a common-mode voltage signal equal to approximately $V_{IN}/2$. Further processing of this signal may necessarily be limited to high common-mode rejection techniques such as instrumentation or isolation amplifiers. However, if the bridge is driven from a pair of bipolar supplies, then the common-mode voltage is ideally eliminated and the restrictions on any processing elements that follow are relaxed.

As shown in Figure 15, the AD688 is an excellent choice for the control element in a bipolar bridge driver scheme. Transistors Q1 and Q2 serve as series pass elements to boost the current drive capability to the 57 mA required by the typical 350 Ω bridge. A differential gain stage may still be required if the bridge balance is not perfect.

Low Cost, Precision 2.5V IC References

AD1403/AD1403A*

FEATURES

Improved, Lower Cost, Replacements for Standard 1403, 1403A
3-Terminal Device: Voltage In/Voltage Out
Laser Trimmed to High Accuracy: 2.500V ±10mV (AD1403A)
Excellent Temperature Stability: 25ppm/°C (AD1403A)
Low Quiescent Current: 1.5mA max
10mA Current Output Capability
Low Cost
Convenient Mini-DIP Package

FUNCTIONAL BLOCK DIAGRAM

8 PIN MINI-DIP

PRODUCT DESCRIPTION

The AD1403 and AD1403A are improved three-terminal, low cost, temperature compensated, bandgap voltage references that provide a fixed 2.5V output voltage for inputs between 4.5V and 40V. A unique combination of advanced circuit design and laser-wafer-trimmed thin-film resistors provides the AD1403/AD1403A with an initial tolerance of ±10mV and a temperature stability of better than 25ppm/°C. In addition, the low quiescent current drain of 1.5mA (max) offers a clear advantage over classical Zener techniques.

The AD1403 or AD1403A is recommended as a stable reference for all 8-, 10- and 12-bit D-to-A converters that require an external reference. In addition, the wide input range of the AD1403/AD1403A allows operation with 5 volt logic supplies, making these devices ideal for digital panel meter applications and when only a single logic supply is available.

The AD1403 and AD1403A are specified for operation over the 0 to +70°C temperature range. The AD580 series of 2.5 volt precision IC references is recommended for applications where operation over the −55°C to +125°C range is required.

PRODUCT HIGHLIGHTS

1. The AD1403A offers improved initial tolerance over the industry-standard 1403A: ±10mV versus ±25mV at a lower cost.
2. The three-terminal voltage in/voltage out operation of the AD1403/AD1403A provides a regulated output voltage without any external components.
3. The AD1403/AD1403A provides a stable 2.5V output voltage for input voltages between 4.5V and 40V making these devices ideal for systems that contain a single logic supply.
4. Thin film resistor technology and tightly controlled bipolar processing provide the AD1403A with temperature stabilities of 25ppm/°C.
5. The low 1.5mA maximum quiescent current drain of the AD1403 and AD1403A makes them ideal for CMOS and other low power applications.

6

Some confusion exists in the area of defining and specifying reference voltage error over temperature. Historically, references are characterized using a maximum deviation per degree Centigrade; i.e., 10ppm/°C. However, because of the inconsistent nonlinearities in zener references (butterfly or "S" type characteristics), most manufacturers use a maximum limit error band approach to characterize their references. This technique measures the output voltage at 3 to 5 different temperatures and guarantees that the output voltage deviation will fall within the guaranteed error band at these discrete temperatures. This approach, of course, makes no mention or guarantee of performance at any other temperature within the operating temperature range of the device.

The consistent Voltage vs. Temperature performance of a typical AD1403 is shown in Figure 6. Note that the characteristic is quasi-parabolic, not the possible "S" type characteristics of classical zener references. This parabolic characteristic permits a maximum output deviation specification over the device's full operating temperature range, rather than just at 3 to 5 discrete temperatures.

The AD1403 exhibits a worst-case shift of 7.5mV over the entire range of operating input voltage, 4.5 volts to 40 volts. Typically, the shift is less than 1mV as shown in Figure 3.

THE AD1403A AS A LOW POWER, LOW VOLTAGE PRECISION REFERENCE FOR DATA CONVERTERS

The AD1403A has a number of features that make it ideally suited for use with A/D and D/A data converters used in complex microprocessor-based systems. The calibrated 2.500 volt output minimizes user trim requirements and allows operation from a single low voltage supply. Low power consumption (1.5mA quiescent current) is commensurate with that of CMOS-type devices, while the low cost and small package complements the decreasing cost and size of the latest converters.

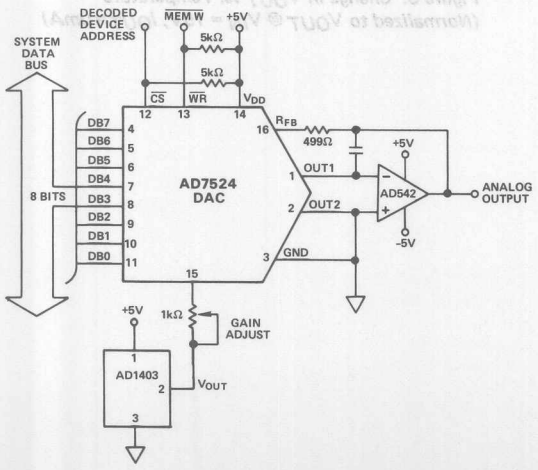

Figure 7. Low Power, Low Voltage Reference for the AD7524 Microprocessor-Compatible 8-Bit DAC

AD7524 low-cost 8-bit CMOS DAC with complete microprocessor interface. The AD1403A and the AD7524 are specified to operate from a single 5 volt supply; this eliminates the need to provide a +15 volt power supply for the sole purpose of operating a reference. The AD7524 includes an 8-bit data register, and address decoding logic; it may thus be interfaced directly to an 8- or 16-bit data bus. Only 300μA of quiescent current from the single +5 volt supply is required to operate the AD7524 which is packaged in a small 16 pin DIP. The AD542 output amplifier is also low power, requiring only 1.5mA quiescent current. Its laser-trimmed offset voltage preserves the ±1/2LSB linearity of the AD7524KN without user trims and it typically settles to ±1/2LSB in less than 5 microseconds. It will provide the 0 volt to −2.5 volt output swing from ±5 volt supplies.

THE AD1403 AS A PRECISION PROGRAMMABLE CURRENT SOURCE

The AD1403 is an excellent building block for precision current sources. Its wide range of operating voltages, 4.5V to 40V, along with excellent line regulation over that range (7.5mV) result in high insensitivity to varying load impedances. The low quiescent current (I_I) of 1.5mA (max) and the maximum specified maximum load current of 10mA allows the user to program current to any value between 1.5mA and 10mA.

Figure 10a shows the AD1403 connected as a current source. Total current is equal to the quiescent current plus the load current. Most of the temperature coefficient comes from the quiescent current term I_I, which has a typical TC of 0.13%/°C (1300ppm/°C). The load voltage (and hence current) TC is much lower at ±40ppm/°C max (AD1403). Therefore, the overall temperature coefficient decreases rapidly as the load current is increased. Figure 10b shows the typical temperature coefficient for currents between 1.5mA and 10mA. Use of an AD1403A will not improve the TC appreciably.

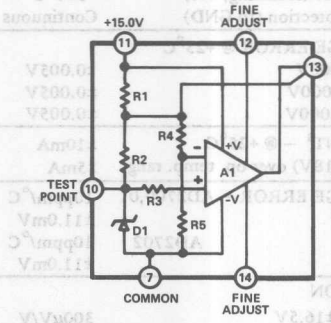
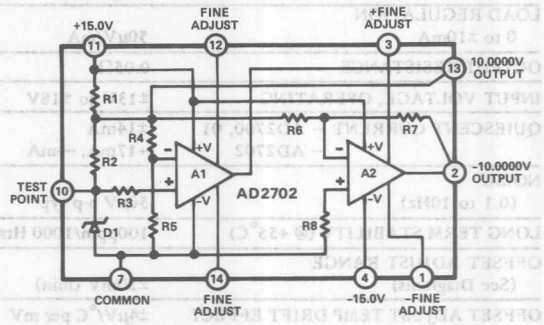
ANALOG DEVICES



±10 Volt Precision Reference Series



AD2700/AD2701/AD2702

FEATURES

- Very High Accuracy: 10.000 Volts ±2.5mV (L and U)
- Low Temperature Coefficient: 3ppm/°C
- Performance Guaranteed -55°C to +125°C
- 10mA Output Current Capability
- Low Noise
- Short Circuit Protected
- Available as /883B

FUNCTIONAL BLOCK DIAGRAMS

PRODUCT DESCRIPTION

The AD2700 family of precision 10 volt references offer the user excellent accuracy and stability at a moderate price by combining the recognized advantages of thin film technology and active laser trimming. The low temperature drift (3ppm/°C) achieved with these technologies can be matched only by the use of ovens, chip heaters for temperature regulation, or with hand selected components and manual trimming. In addition, temperature-regulated devices are guaranteed only up to +85°C operation, whereas the U- and S-grade devices in the AD2700 family are guaranteed to +125°C.

The AD2700 is a +10 volt reference which is designed to interface with high accuracy bipolar D/A converters of 10 and 12 bit resolution. The 10mA output drive capability also makes the AD2700 ideal for use as a general positive system reference.

The AD2701 is a negative 10 volt reference especially designed to interface with CMOS D/A and A/D converters, as shown in the applications. For systems requiring a dual tracking reference, the AD2702 offers both positive and negative precision 10 volt outputs in a single package. Both are often used with 52XX Series 12-bit A/D converters which require -10V external references for high accuracy over wide temperature ranges.

All three devices are offered in "J" and "L" grades for operation from -25°C to +85°C and "S" and "U" grades for the -55°C to +125°C temperature range. Screening to MIL-STD-883 is available for "S" and "U" grades of the AD2700 family.

PRODUCT HIGHLIGHTS

1. Active laser trimming of both initial accuracy and temperature performance results in very high accuracy over the temperature range without external components. The AD2700/01/02 LD grades have a maximum output voltage error at 25°C of ±2.5mV with no external adjustments.
2. The performance of the AD2700 series is achieved by a well-characterized design and precise control over the manufacturing process.
3. The AD2700 series is well suited for a broad range of applications requiring an accurate, stable reference source such as high resolution data converters (12 or 14 bits), test and measurement systems and calibration standards.

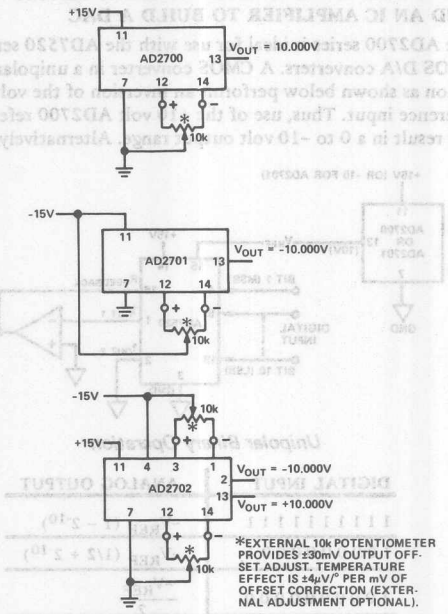
[1] Specified with resistive load to common. Device not intended for use in driving a dynamic load.

[2] Output voltage error as a function of temperature is determined using the box method. Each unit is tested at T_{min}, T_{max} and +25°C. At each temperature V_{OUT} must fall within the rectangular area bounded by the minimum and maximum temperature and whose maximum V_{OUT} value is equal to V_{OUT} nominal plus or minus the maximum +25°C error plus the maximum drift error from +25°C. The box limits are noted below the drift values used to calculate the box.



[3] Analog Devices reserves the right to ship side-brazed ceramic packages (outline DH-14D) in lieu of the standard ceramic packages for J and L grade parts.

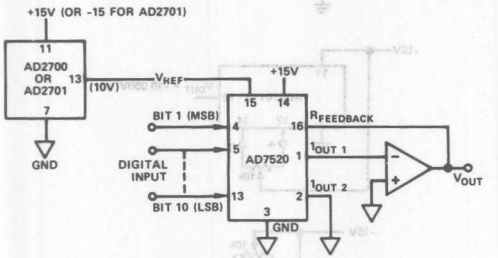
Pin Designations



Fine Trim Connections

Using AD2702 Reference with the Fast, High Accuracy AD5215 – 12-Bit ADC

USING AD2700 REFERENCE WITH THE AD7520 AND AN IC AMPLIFIER TO BUILD A DAC

The AD2700 series is ideal for use with the AD7520 series of CMOS D/A converters. A CMOS converter in a unipolar application as shown below performs an inversion of the voltage reference input. Thus, use of the +10 volt AD2700 reference will result in a 0 to −10 volt output range. Alternatively, using the −10 volt AD2701 will result in a 0 to +10 volt range. Two operational amplifiers are used to give a bipolar output range of −10 volt to +10 volt, as shown in the lower figure. Either the AD2700 or AD2701 can be used, depending on the transfer code characteristic desired. For more detailed applications information, refer to the AD7520 Data Sheet.

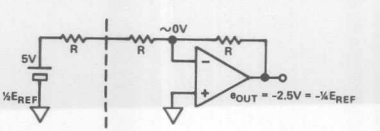
Table II. Code Table — Bipolar (Offset Binary) Operation

USING THE AD2700 VOLTAGE REFERENCE WITH D/A CONVERTER



An AD2700 Voltage Reference can be used with an inverting operational amplifier and an R-2R ladder network. If all bits but the MSB are off (i.e., grounded), the output voltage is $(-R/2R)E_{REF}$. If all bits but Bit 2 are off, it can be shown that the output voltage is $\frac{1}{2}(-R/2R)E_{REF} = \frac{1}{4}E_{REF}$: The lumped resistance of all the less-significant-bit circuitry (to the left of Bit 2) is 2R; the Thevenin equivalent looking back from the MSB towards Bit 2 is the generator, $E_{REF}/2$, and the series resistance 2R; since the grounded MSB series resistance, 2R, has virtually no influence — because the amplifier summing point is at virtual ground — the output voltage is therefore $-E_{REF}/4$. The same line of thinking can be employed to show that the nth bit produces an increment of output equal to 2^{-n} E_{REF}.

±10.000 Volt Ultrahigh Precision Reference Series

AD2710/AD2712

FEATURES

Laser Trimmed to High Accuracy: 10.000V ± 1.0mV
Low Temperature Coefficient: 1ppm/°C (L Grade)
Excellent Long Term Stability: 25ppm/1000hrs.
5mA Output Current Capability
Low Noise: 30μV p-p
Short Circuit Protected
No Heater Utilized
Small Size (Standard 14-Pin DIP Package)

FUNCTIONAL BLOCK DIAGRAMS

PRODUCT DESCRIPTION

The AD2710 and AD2712 are temperature-compensated, hybrid voltage references which provide precise 10.000V output from an unregulated input level from 13.5 to 16.5 volts. Active laser trimming is used to trim both the initial error at +25°C as well as the temperature coefficient, which results in ultra high precision performance previously available only in oven-regulated modules. The 1.0mV maximum initial error and 1ppm/°C guaranteed maximum temperature coefficient of the AD2710L and AD2712L represent the best performance combination available without using ovens or heated substrates for temperature regulation.

The AD2710 series of precision 10.000 volt references offer the user unequalled accuracy and stability with performance guaranteed over the 0 to +70°C temperature range. The devices combine the recognized advantages of thin film technology and active laser trimming with a unique integrated ceramic package design to provide an excellent reference for use in applications requiring high accuracy and stability.

The AD2710 is recommended for use as a reference for 10-, 12- and 14-bit D/A converters which require an external reference. The device is also suitable for many types of high resolution A/D converters, either successive approximation or integrating designs. The 5mA output drive capability of the device also makes the AD2710 ideal for use as a master system reference.

For systems requiring a dual tracking reference, the AD2712 offers both positive and negative outputs in a single package. All units are packaged in an integrated ceramic 14-pin side-brazed package offering superior reliability over other package designs.

PRODUCT HIGHLIGHTS

1. Active laser trimming of both initial accuracy and temperature coefficient results in very high accuracy over the temperature range without the use of external components. AD2710 has a maximum deviation from 10.000 volts of ±1.00mV at 25°C with no external adjustments.
2. The AD2710 and AD2712 are well suited for a broad range of applications requiring an accurate, stable reference source such as data converters, test and measurement systems and calibration standards.
3. The performance of the AD2710 series is achieved by a well-characterized design and close control over the manufacturing process. This eliminates the need for temperature-controlled ovens to provide stability.
4. The advanced multilayer integrated ceramic package results in superior electrical performance as well as inherent high reliability.

NOTES
*Same as AD2710KN. **Same as AD2712KN performance.
[1] Specifications apply to both outputs of the AD2712.
[2] Refer to next page for definition of temperature-related error specifications.
[3] The AD2710LN and AD2712LN outputs are guaranteed for a maximum ±2ppm/°C temperature coefficient over the +15°C to +25°C temperature range. Refer to Figure 1.
[4] The +10V and −10V outputs of the AD2712 typically track within ±1ppm/°C over the specified temperature range.
[5] Negative power supply not required for AD2710.
[6] Use of the output trim will change the temperature coefficient approximately 0.3ppm/°C for each millivolt of adjustment.
[7] For outline information see Package Information section.

Specifications subject to change without notice.

UNDERSTANDING THE SPECIFICATIONS

The AD2710 and AD2712 precision references are designed for applications requiring both the lowest possible initial error at room temperature and the lowest possible temperature drift. The specification for initial error is relatively straight-forward, and is the absolute error from exactly 10.000V. The specification for temperature drift, however, must be explained.

Various methods have been used to specify the temperature drift of voltage references, including the "butterfly", "box", and "modified-box" (or total error) methods. The AD2710 and AD2712 are specified with the "butterfly" method.

Using three or more temperatures provides the user with a tighter drift specification, eliminating possible mid-range excursions. The AD2710 and AD2712 have been designed and characterized as having a smooth drift curve with a virtually straight segment from +25°C to +70°C. The typical curve as shown is concave downward and gradually increases slope near 0°C.

As can be seen from Figure 1, the AD2710L and AD2712L +10V outputs will exhibit a maximum temperature coefficient of ±1ppm/°C (±2ppm/°C for "K" grade) from +25°C to +70°C. Over the short range between +15°C and +25°C, the AD2710L and AD2712L +10V outputs have a maximum drift of only ±2ppm/°C and a maximum drift of ±5ppm/°C from 0 to +15°C. The negative output of the AD2712L has a similar temperature coefficient characteristic with a maximum slope of ±2ppm/°C from +25°C to +70°C. This limit continues from +25°C to +15°C and then increases to a ±5ppm/°C maximum slope from +15°C and 0°C. Every unit is 100 percent tested and guaranteed to meet these specifications over the full 0 to +70°C temperature range.

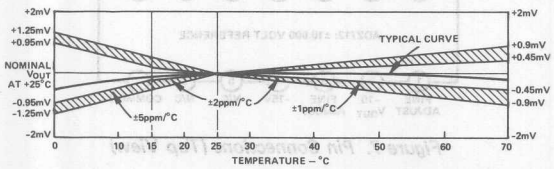

Figure 1. Maximum Change from +10V Output from +25°C Value vs. Temperature

All grades of the AD2710 and AD2712 are tested after a five minute warm-up period. This warm-up allows the entire circuit to attain thermal equilibrium. The warm-up drift is approximately 500 microvolts and is completely settled approximately three minutes after turn-on. Figure 2 shows the typical warm-up characteristics of the AD2710.

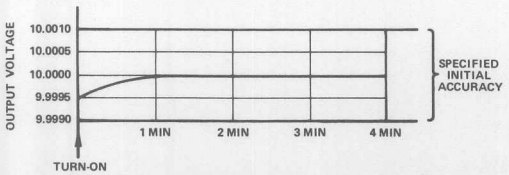

Figure 2. AD2710 Typical Warm-Up Drift

USING THE AD2710 AS A DAC REFERENCE

Digital-to-analog converters require a reference to establish the full scale output range. It is this reference which will ultimately determine the absolute accuracy of the converter. While many converters include internal reference sources, better overall performance can be obtained if a higher precision external reference is used.

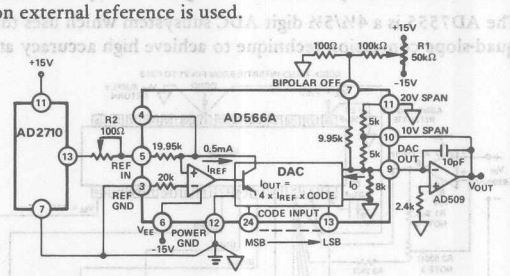

Figure 3. Low Drift 12-Bit D/A Converter

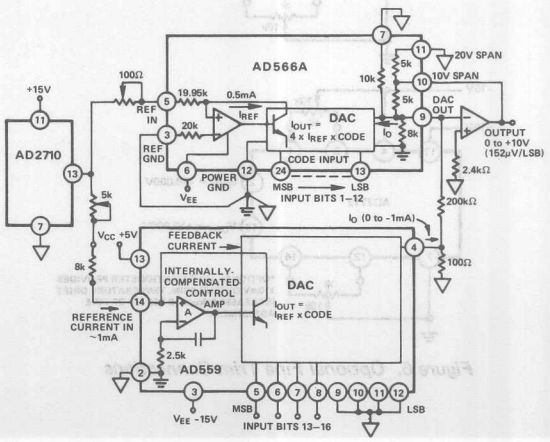
Figure 3 shows the AD2710 used with the AD566A high-speed 12-bit DAC. The AD566AKD is laser trimmed for ±1/4LSB maximum nonlinearity, and exhibits a gain temperature coefficient of 3ppm/°C. Use of the AD2710LN reference will result in a worst case total gain temperature coefficient of 4ppm/°C. After initial calibration of the DAC scale factor at room temperature, 12-bit absolute accuracy can be maintained over the +15°C to +70°C temperature range. The high output current capability of the AD2710 allows it to serve as a reference for up to 10 such converters in a system.

The resolution of the AD566A can be extended as shown in Figure 3 by summing the output of another DAC. In this example, an AD559 is used to provide 4 additional bits. Since the AD559 is driven from the same AD2710 reference as the AD566A which provides the higher-order bits, and uses a similar internal thin-film resistor ladder, it will exhibit first-order temperature tracking. While this circuit provides 16-bits of resolution, it is only as accurate as the AD566A used for the most significant bits. Use of an AD566AKD will typically achieve ±0.003% accuracy (±1/2LSB at 14 bits).



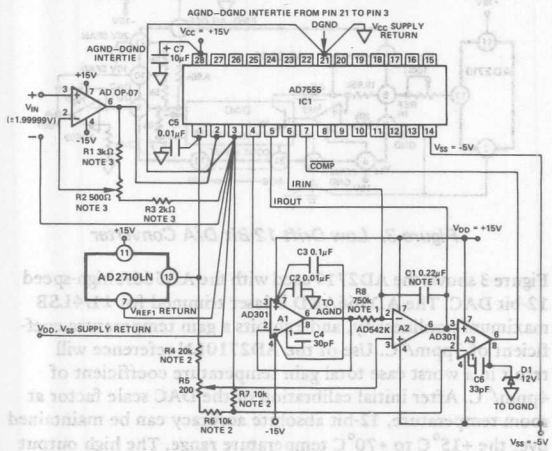


Figure 4. 16-Bit Binary DAC with AD2710 Reference

lent absolute accuracy and low temperature drift allow low-cost measurement systems to offer high levels of performance.

The AD7555 is a 4½/5½ digit ADC subsystem which uses the quad-slope conversion technique to achieve high accuracy at

NOTES:
1. R8 C1 VALUES SHOWN ARE FOR 5 1/2 DIGIT MODE. FOR 4 1/2 DIGIT MODE R_8 = 360k, C_1 = 0.22μF. SUITABLE CAPACITORS AVAILABLE FROM COMPONENT RESEARCH CO. INC., 1655 26th STREET, SANTA MONICA, CA, 90404. (STOCK NUMBER FOR 0.22μF CAPACITOR IS D11B224KXW).
2. R4, R6, R7 1% TOLERANCE.
3. R1, R3 SHOULD TRACK WITHIN 0.5ppm/°C. EITHER BULK METAL OR WIRE-WOUND RESISTORS (OR A THIN-FILM NETWORK) SHOULD BE USED. R2 SHOULD BE A LOW-TC TYPE POTENTIOMETER OR A SELECTED LOW DRIFT FIXED RESISTOR.

Figure 5. High Accuracy Low Drift A/D Converter

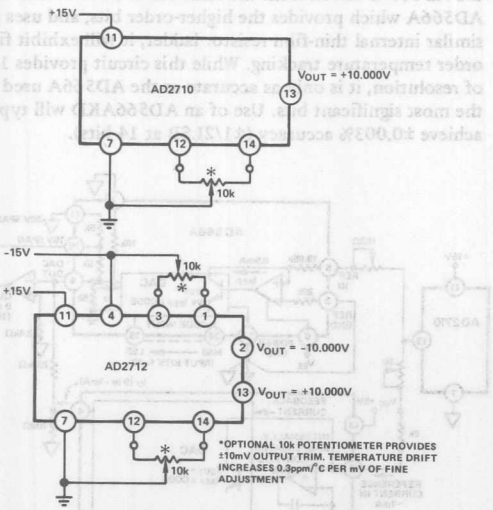

Figure 6. Optional Fine Trim Connections

1.2ppm/°C is possible using the AD2710L reference and medium-precision external amplifiers. This represents a full scale drift of less than ±10 counts in ±200,000 from +15°C to +45°C. Less than 1 count of drift will occur in the 4 1/2 digit mode.

The AD7555 was designed for use with a 4.096V reference, which produces a ±2 volt input range. When the AD2710 is used, the input range is increased to ±4.88281V (24.4μV/count). The new scaling can be handled either by using a precision gain stage before the AD7555 analog input as shown or by using a microprocessor to digitally correct the scale. The actual input signal value can be computed by multiplying the count produced by the AD7555 by V_{REF1} (10 volts in this case), and dividing the result by 409600. Details of the digital circuitry of the AD7555 can be found on the AD7555 data sheet.

It should be noted that when the AD7555 is used with the AD2710 10 volt reference, it is necessary to use a V_{CC} greater than 10 volts. Thus the digital inputs and outputs of the ADC will be compatible with CMOS logic levels.

GENERAL DESCRIPTION

The REF-01 precision voltage reference provides a stable +10V output which can be adjusted over a ±3% range with minimal effect on temperature stability. Single-supply operation over an input voltage range of 12V to 40V, low current drain of 1mA, and excellent temperature stability are achieved with an improved bandgap design. Low cost, low noise, and low power make the REF-01 an excellent choice whenever a stable voltage reference is required. Applications include D/A and A/D converters, portable instrumentation, and digital voltmeters. Full military temperature range devices with screening to MIL-STD-883 are available. For guaranteed long-term drift see the REF-10 data sheet.

4. Line and Load Regulation specifications include the effect of self heating.
5. Guaranteed by design.
6. Sample tested.
7. During sink current test the device meets the output voltage specified.

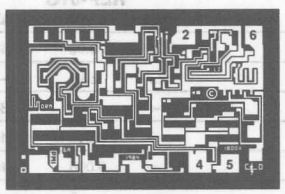
OUTPUT ADJUSTMENT



The REF-01 trim terminal can be used to adjust the output voltage over a 10V ±300mV range. This feature allows the system designer to trim system errors by setting the reference to a voltage other than 10V. Of course, the output can also be set to exactly 10.000V, or to 10.240V for binary applications.

Adjustment of the output does not significantly affect the temperature performance of the device. The temperature coefficient change is approximately 0.7 ppm/° C for 100mV of output adjustment.

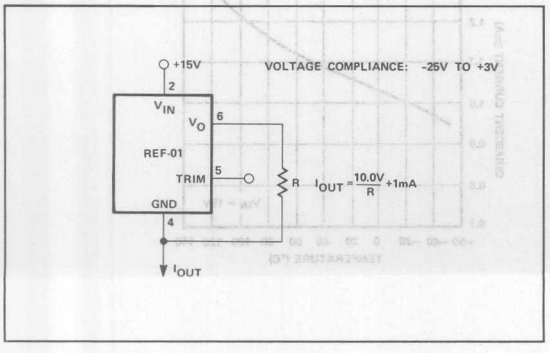
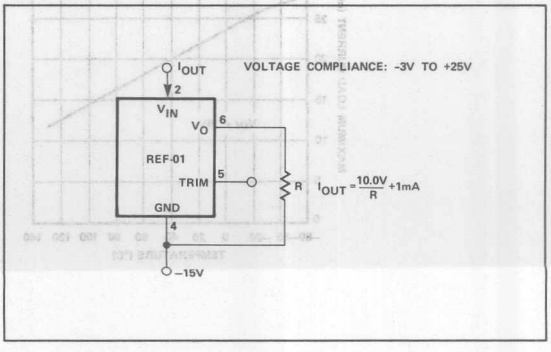
A/D CONVERTER REFERENCE

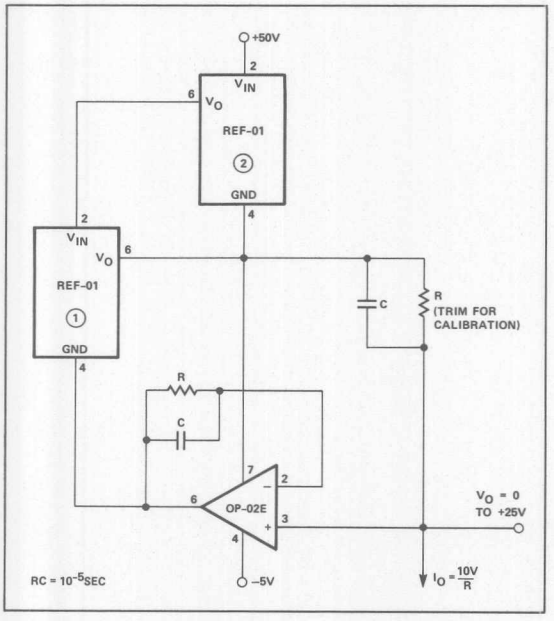


PRECISION CALIBRATION STANDARD



±10V REFERENCE

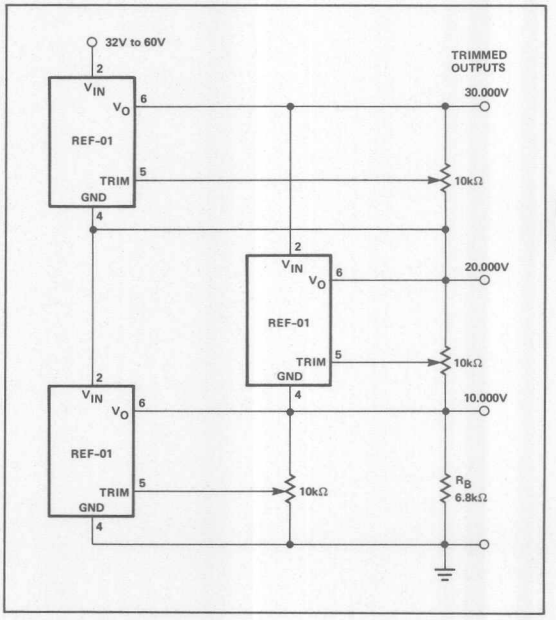
CURRENT SOURCE



CURRENT SINK

PRECISION CURRENT SOURCE

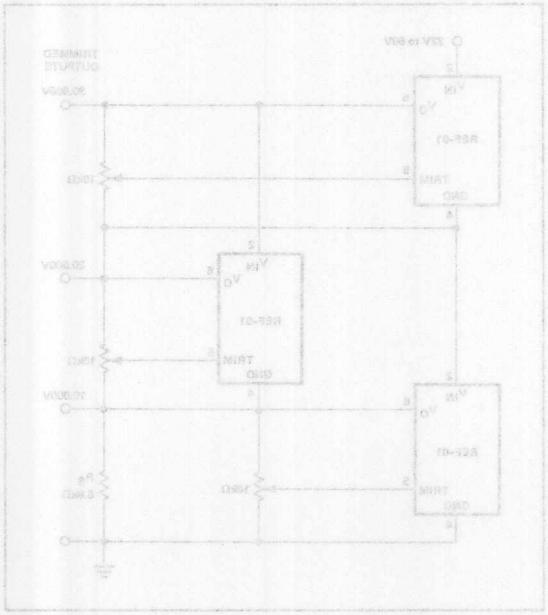
A current source with 25V output compliance and excellent output impedance can be obtained using this circuit. REF-01 (2) keeps the line voltage and power dissipation constant in device (1); the only important error consideration at room temperature is the negative supply rejection of the op amp. The typical 3μV/V PSRR of the OP-02E will create an 8ppm change (3μV/V × 25V/10V) in output current over a 25V range. For example, a 10mA current source can be built (R = 1kΩ) with 300MΩ output impedance.



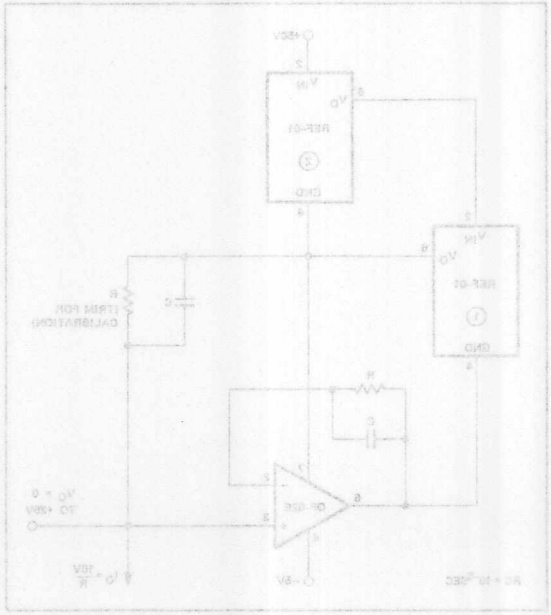
$$R_O = \frac{25V}{8 \times 10^{-6} \times 10mA}$$

REFERENCE STACK WITH EXCELLENT LINE REGULATION

Three REF-01's can be stacked to yield 10.000, 20.000, and 30.000V outputs. An additional advantage is near-perfect line regulation of the 10.0V and 20.0V output. A 32V to 60V input change produces an output change which is less than the noise voltage of the devices. A load bypass resistor (R_B) provides a path for the supply current (I_{SY}) of the 20.000V regulator.



In general, any number of REF-01's can be stacked this way. For example, ten devices will yield outputs of 10, 20, 30 . . . 100V. The line voltage can range from 105V to 130V. However, care must be taken to ensure that the total load currents do not exceed the maximum usable current (typically 21mA).



SUPPLY BYPASSING

For best results, it is recommended that the power supply pin is bypassed with a 0.1μF disc ceramic capacitor.

+5V Precision Voltage Reference/Temperature Transducer

REF-02

FEATURES

- 5 Volt Output ..... ±0.3% Max
- Temperature Voltage Output ..... 2.1mV/°C
- Adjustment Range ..... ±3% Min
- Excellent Temperature Stability ..... 8.5ppm/°C Max
- Low Noise ..... $15\mu V_{p-p}$ Max
- Low Supply Current ..... 1.4mA Max
- Wide Input Voltage Range ..... 7V to 40V
- High Load-Driving Capability 20mA
- No External Components
- Short-Circuit Proof
- MIL-STD-883 Screening Available
- Available in Die Form

GENERAL DESCRIPTION

The REF-02 precision voltage reference provides a stable +5V output which can be adjusted over a ±6% range with minimal effect on temperature stability. Single-supply operation over an input voltage range of 7V to 40V, low current drain of 1mA, and excellent temperature stability are achieved with an improved bandgap design. Low cost, low noise, and low power make the REF-02 an excellent choice whenever a stable voltage reference is required. Applications include D/A and A/D converters, portable instrumentation, and digital voltmeters. The versatility of the REF-02 is enhanced by its use as a monolithic temperature transducer. For +10V references, see the REF-01 and REF-10 data sheets.

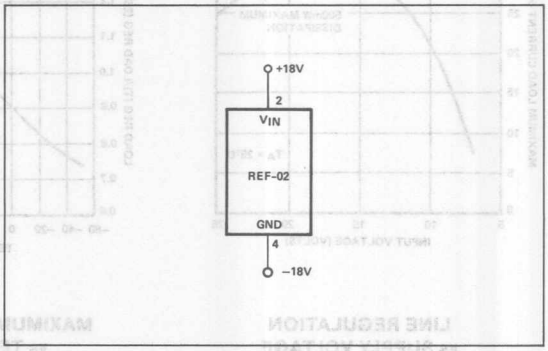
OUTPUT ADJUSTMENT



The REF-02 trim terminal can be used to adjust the output voltage over a 5V ±300mV range. This feature allows the system designer to trim system errors by setting the reference to a voltage other than 5V. Of course, the output can also be set to exactly 5.000V or to 5.12V for binary applications.

Adjustment of the output does not significantly affect the temperature performance of the device. Typically, the temperature coefficent change is 0.7ppm/° C for 100mV of output adjustment.

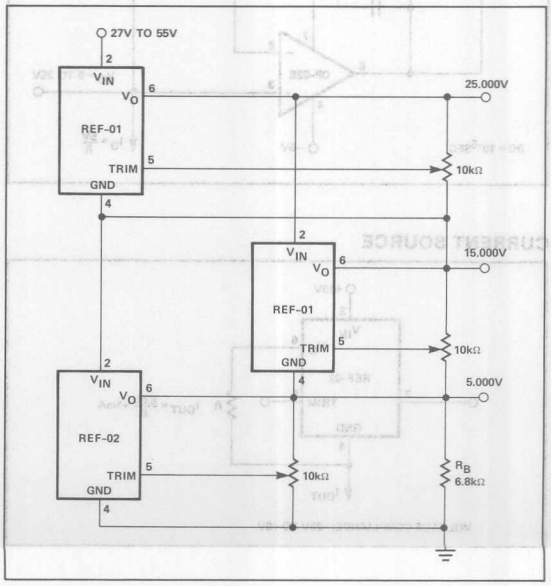
TYPICAL TEMPERATURE VOLTAGE OUTPUT vs TEMPERATURE (REF-02A)

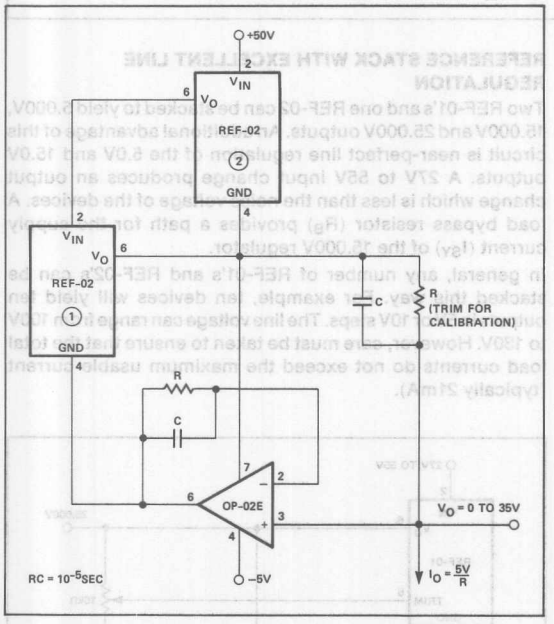


TEMPERATURE CONTROLLER

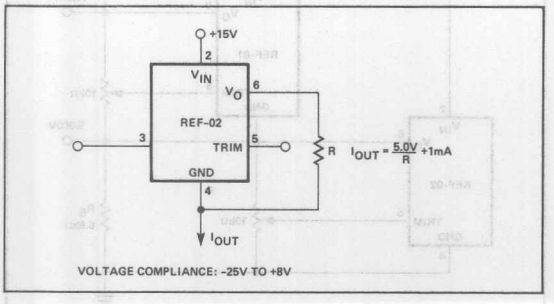
REFERENCE STACK WITH EXCELLENT LINE REGULATION

Two REF-01's and one REF-02 can be stacked to yield 5.000V, 15.000V and 25.000V outputs. An additional advantage of this circuit is near-perfect line regulation of the 5.0V and 15.0V outputs. A 27V to 55V input change produces an output change which is less than the noise voltage of the devices. A load bypass resistor (R_B) provides a path for the supply current (I_{SY}) of the 15.000V regulator.

In general, any number of REF-01's and REF-02's can be stacked this way. For example, ten devices will yield ten outputs in 5V or 10V steps. The line voltage can range from 100V to 130V. However, care must be taken to ensure that the total load currents do not exceed the maximum usable current (typically 21mA).

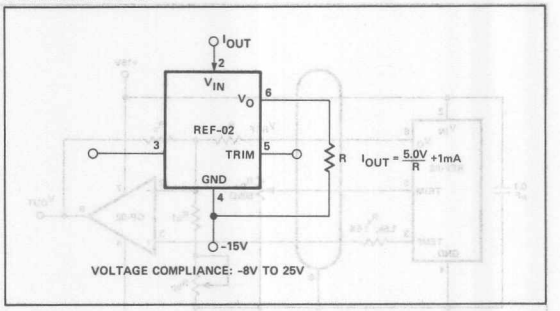


6



PRECISION CURRENT SOURCE

A current source with 35V output compliance and excellent output impedance can be obtained using this circuit. REF-02 ② keeps the line voltage and power dissipation constant in device ①; the only important error consideration at room temperature is the negative supply rejection of the op amp. The typical 3μV/V PSRR of the OP-02E will create a 20ppm change (3μV/V × 35V/5V) in output current over a 35V range. For example, a 5mA current source can be built (R = 1kΩ) with 350MΩ output impedance.



$$R_O = \frac{35V}{20 \times 10^{-6} \times 5mA}$$

†† For availability and burn-in information on SO and PLCC packages, contact your local sales office.

GENERAL DESCRIPTION

The REF-03 precision voltage reference provides a stable +2.5V output, with minimal change for variations in supply voltage, ambient temperature or loading conditions. Single-supply operation over an input voltage range of +4.5V to +33V with a current drain of 1mA and good temperature stability is achieved using an improved bandgap design. Primarily targeted at price-sensitive applications, the REF-03 is available in plastic mini-dips and surface-mountable small outline plastic packages. For improved performance or −55°C/125°C operation, see the REF-43 data sheet.

APPLICATIONS INFORMATION

The REF-03 provides a stable +2.5V output voltage with minimal dependence on load current, line voltage or temperature. This voltage is typically used to set an absolute reference point in data conversion circuits, or in analog circuits such as log amps, 4-20mA transmitters and power supplies. The REF-03 is of particular value in systems requiring a precision reference using a single +5V supply rail.

Because an onboard operational amplifier is used to amplify the basic bandgap cell voltage to 2.5V, supply decoupling is critical to the transient performance of a voltage reference. The supply line should be bypassed with a 10μF tantalum capacitor in parallel with a 0.01μF to 0.1μF ceramic capacitor for best results as shown in Figure 1. For less critical conditions, a single 0.1μF capacitor is adequate. The bypass capacitors should be located as close to the reference as possible. Inadequate bypassing can lead to instabilities.

Output bypass capacitors are not generally recommended. If necessary for high-frequency output impedance reduction, the capacitance value used should be at least 1μF.

FIGURE 1: Basic Connections

GENERATING AN ADJUSTABLE BIPOLAR VOLTAGE REFERENCE

Many times, there is a requirement for an adjustable bipolar reference. A simple method of generating such a reference is to connect the output of the REF-03 to an op amp in an adjustable gain configuration as shown in Figure 2. The trimable resistor is then used to generate the desired output voltage from −2.5V to +2.5V.

GENERATING A −2.5V REFERENCE

Often, there is a requirement for a negative reference voltage. The simplest method of generating a −2.5V reference with the REF-03 is to connect an op amp in a gain of −1 to the output, as shown in Figure 3. This provides both positive and negative 2.5V references. Figure 4 shows another method of obtaining a negative reference, in which the current-output element is a PNP transistor, with the REF-03 in a servo loop to ensure that the output remains 2.5V below ground.

FIGURE 2: Adjustable Bipolar Reference

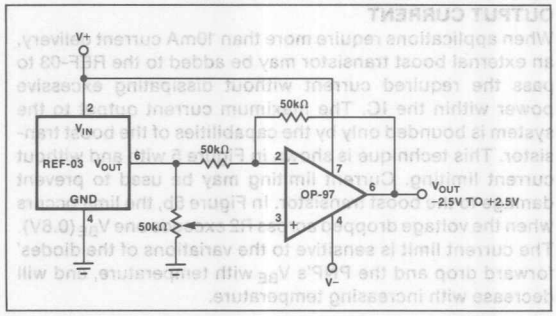

FIGURE 3: ±2.5V Reference

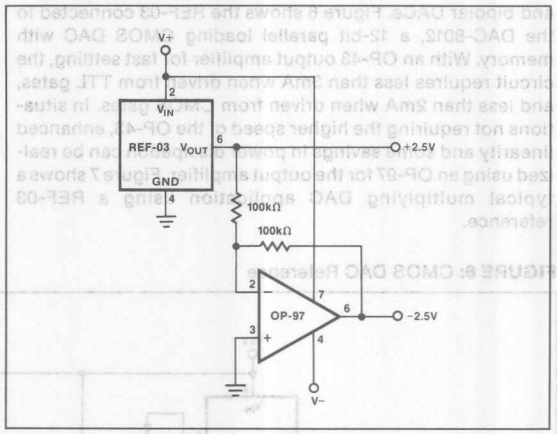

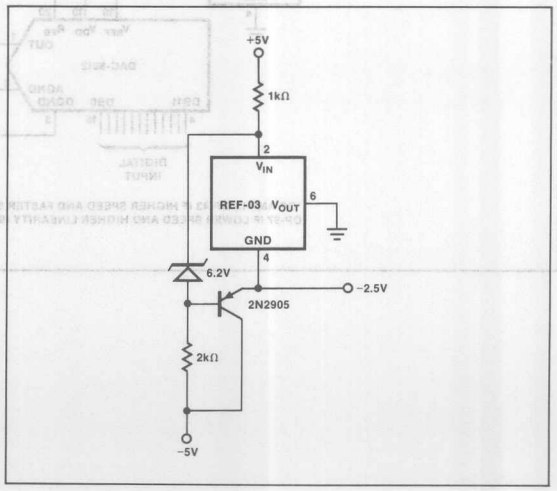

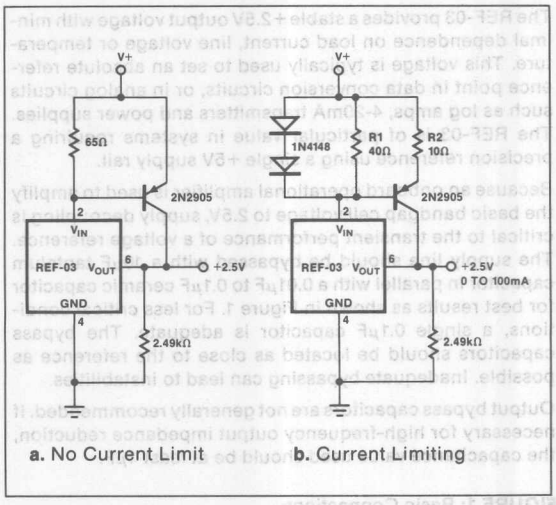

FIGURE 4: −2.5V Reference

BOOST TRANSISTOR PROVIDES HIGH OUTPUT CURRENT

When applications require more than 10mA current delivery, an external boost transistor may be added to the REF-03 to pass the required current without dissipating excessive power within the IC. The maximum current output to the system is bounded only by the capabilities of the boost transistor. This technique is shown in Figure 5 with and without current limiting. Current limiting may be used to prevent damage to the boost transistor. In Figure 5b, the limit occurs when the voltage dropped across R2 exceeds one V_{BE} (0.6V). The current limit is sensitive to the variations of the diodes' forward drop and the PNP's V_{BE} with temperature, and will decrease with increasing temperature.

FIGURE 5: Output Current Boost

CMOS DAC REFERENCE

The REF-03 makes an excellent reference for use with CMOS and bipolar DACs. Figure 6 shows the REF-03 connected to the DAC-8012, a 12-bit parallel loading CMOS DAC with memory. With an OP-43 output amplifier for fast settling, the circuit requires less than 3mA when driven from TTL gates, and less than 2mA when driven from CMOS gates. In situations not requiring the higher speed of the OP-43, enhanced linearity and some savings in power dissipation can be realized using an OP-97 for the output amplifier. Figure 7 shows a typical multiplying DAC application using a REF-03 reference.

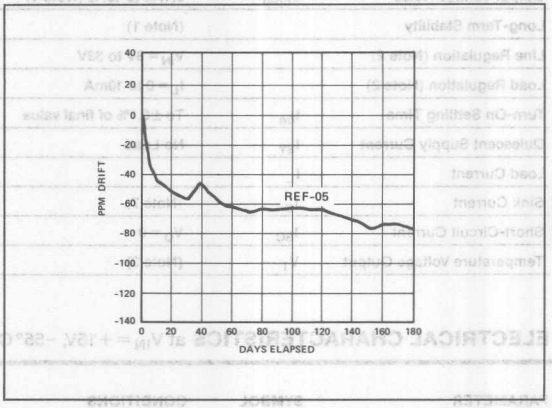
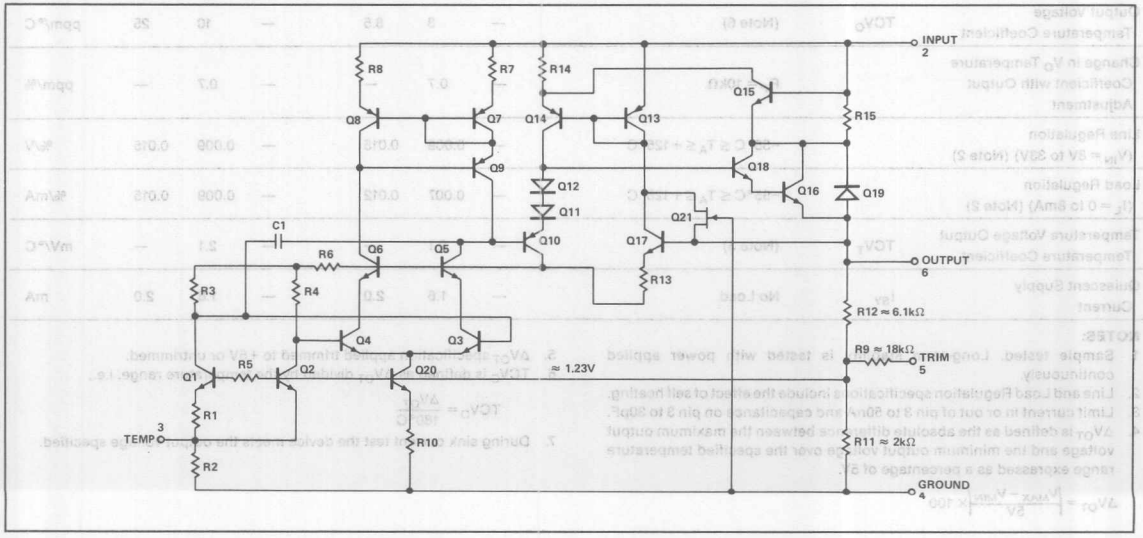
PIN CONNECTIONS & ORDERING INFORMATION



TO-99 (J-Suffix)
REF-05AJ/883
REF-05BJ/883



GENERAL DESCRIPTION

The REF-05 precision voltage reference provides a stable +5V output which can be adjusted over a ±6% range with minimal effect on temperature stability. Long-term drift is guaranteed at 100ppm/1000 hrs. maximum. Single-supply operation over an input voltage range of 7V to 40V, low current drain of 1mA, and excellent temperature stability are achieved with an improved bandgap design. Low cost, low noise, and low power make the REF-05 an excellent choice whenever a stable voltage reference is required. Applications include D/A and A/D converters, portable instrumentation, and digital voltmeters. The versatility of the REF-05 is enhanced by its use as a monolithic temperature transducer. For +10V Precision Voltage References see the REF-10 data sheet.

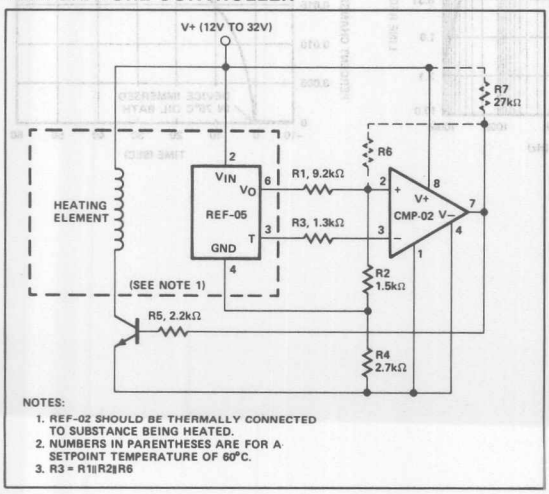
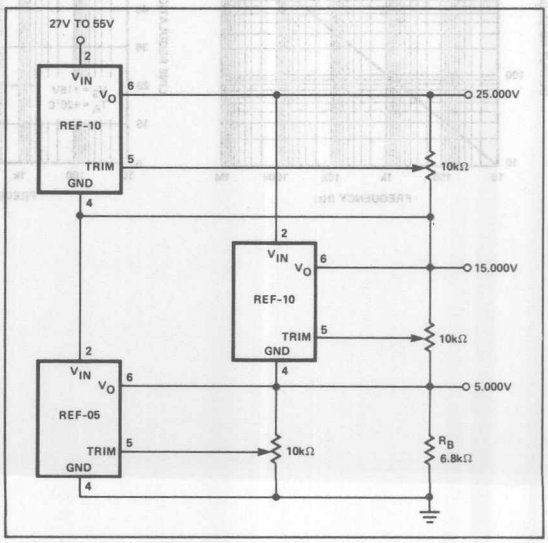
*For 125°C operation, the op amp output must be able to swing to +12.5V; increase V_{IN} to +18V from +15V if necessary.

TYPICAL TEMPERATURE VOLTAGE OUTPUT vs TEMPERATURE (REF-05A)





REFERENCE STACK WITH EXCELLENT LINE REGULATION

Two REF-10's and one REF-05 can be stacked to yield 5V, 15V and 25V outputs. An additional advantage is near-perfect line regulation of the 5V and 15V outputs. A 27V to 55V input change produces an output change which is less than the noise voltage of the devices. A load bypass resistor (R_g) provides a path for the supply current (I_{SY}) of the 15V regulator.

In general, any number of REF-10's and REF-05's can be stacked this way. For example, ten devices will yield ten outputs in 5V or 10V steps. The line voltage can range from 100V to 130V, however, care must be taken to ensure that the total load currents do not exceed the maximum usable current (typically 21mA).

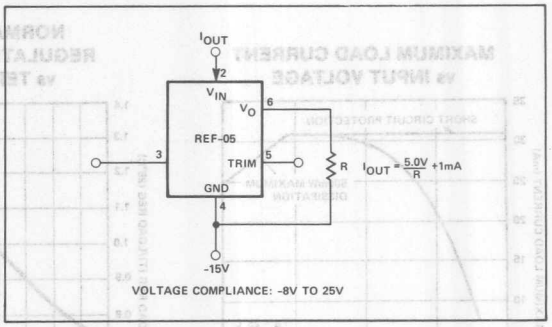
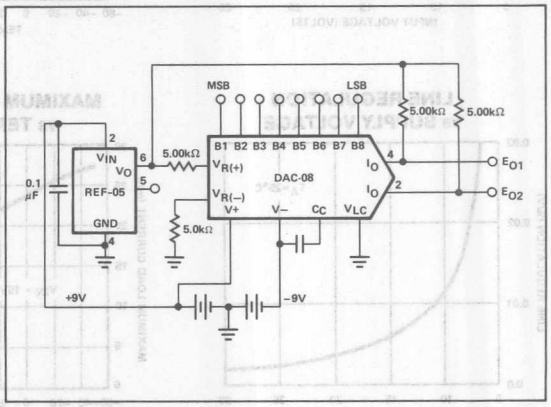
PRECISION CURRENT SOURCE

A current source with 35V output compliance and excellent output impedance can be obtained using this circuit. REF-05 (2) keeps the line voltage and power dissipation constant in device (1); the only important error consideration at room temperature is the negative supply rejection of the op amp. The typical 3μV/V PSRR of the OP-02E will create a 20ppm change (3μV/V × 35V/5V) in output current over a 35V range. For example, a 5mA current source can be built (R = 1kΩ) with 350MΩ output impedance.

$$R_O = \frac{35V}{20 \times 10^{-6} \times 5mA}$$



CURRENT SOURCE



SUPPLY BYPASSING

For best results, it is recommended that the power supply pin is bypassed with a 0.1μF disc ceramic capacitor.

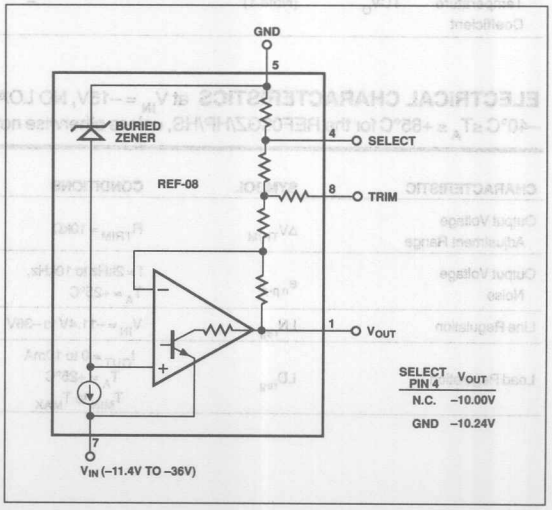
PIN CONNECTIONS

GENERAL DESCRIPTION

The REF-08 is a series regulation, buried Zener, negative voltage reference with pin selectable output voltage. Its low temperature coefficient, low noise, and selectable output make it an ideal reference for A/D converters such as the ADC-908 or the PM-7574. The REF-08 is also well suited for CMOS DAC applications where a positive output voltage is desired.



Applications with 8-bit accuracy will typically be able to use the REF-08 without trimming its output voltage. This is particularly true of CMOS DACs with low gain errors such as the DAC-8408 and PM-7528.

Leaving the SELECT pin open will result in a –10V output. Grounding SELECT will produce a –10.24V output (i.e. –10mV per 10-bit LSB) that is ideal for binary applications.

A ±270mV adjustment range is available with the REF-08 which exhibits a tight 0.04ppm/°C/mV of adjustment temperature coefficient. In many applications, the combined tempcos of an adjusted REF-08 will be superior to more expensive precision references with tighter initial tempcos but greater changes with adjustment.

The REF-08 has been designed to operate from a "worst case" –12V power supply (–11.4V). This low dropout voltage makes the best of the poor supply regulation in some digital systems. Its 10mA output current capability and unloaded supply current of only 2mA provide better power/performance than most traditional op amp inverter circuits.

dependence on load current, input voltage or temperature variations. This single package device works well as an absolute reference point in data conversion circuits, or in analog circuits such as logarithmic amplifiers, strain gauge bridge measurement systems, and power supply circuits. The REF-08 is especially applicable to CMOS data converter circuits that require –10V references.

BASIC CONNECTIONS

Figure 1 shows the connection diagram for the REF-08. For DC loads, no output capacitors are required. For high current load conditions Load Regulation needs consideration. The REF-08 load regulation of 25ppm/mA equates to 0.25Ω of output resistance. To maintain accurate distribution of the reference output voltage to the rest of the system, wiring resistances must be kept as small as is practical.

For dynamic loads the addition of C_O reduces high frequency output resistance which is shown in the R_{OUT} vs. frequency graphs in the typical performance characteristics. This is generally important with A/D converters that have a continuously changing load.

In the typical performance characteristics graph section, the Load Transient response plot shows a 1µs recovery time to a 1mA load current change which is representative of several typical CMOS A/D converters. Choosing the 0.01µF in parallel with a 10µF capacitor for C_O adequately reduces the reference output voltage transient amplitude.

One refinement to further reduce the reference voltage output transient is introduction of R_O in series with the output filter capacitors. R_O should be chosen equal to $1/2\pi C_O f_P$ where C_O is the total output filter capacitance and f_P is the frequency in the R_{OUT} vs. frequency plot at which the peak value of R_{OUT} occurs. This extra resistance, R_O, effectively damps the circuit resonance further reducing the voltage transient during output load changes.

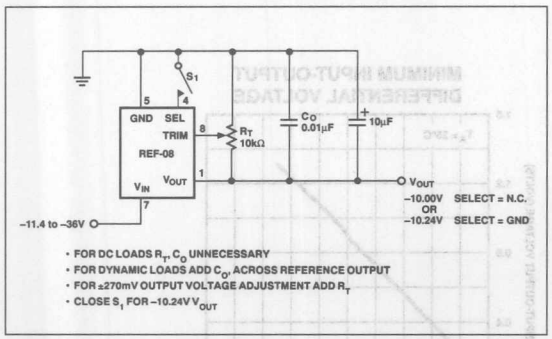

FIGURE 1: *Connection Diagram*

Output voltages within ±270mV of nominal can easily be obtained by addition of the 10k Trimpot*. This range adequately addresses the full-scale adjustment ranges required by CMOS A/D and D/A converters. The effect on the REF-08 output voltage temperature coefficient is a low 0.04ppm/°C per mV of adjustment.

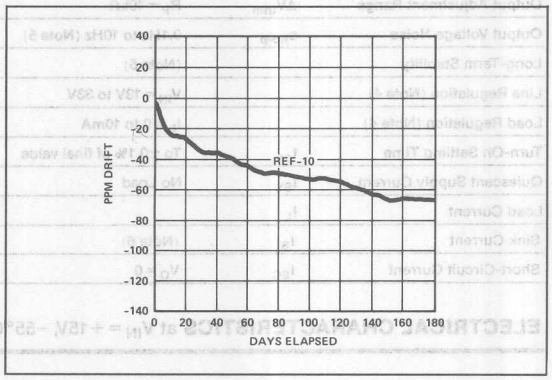
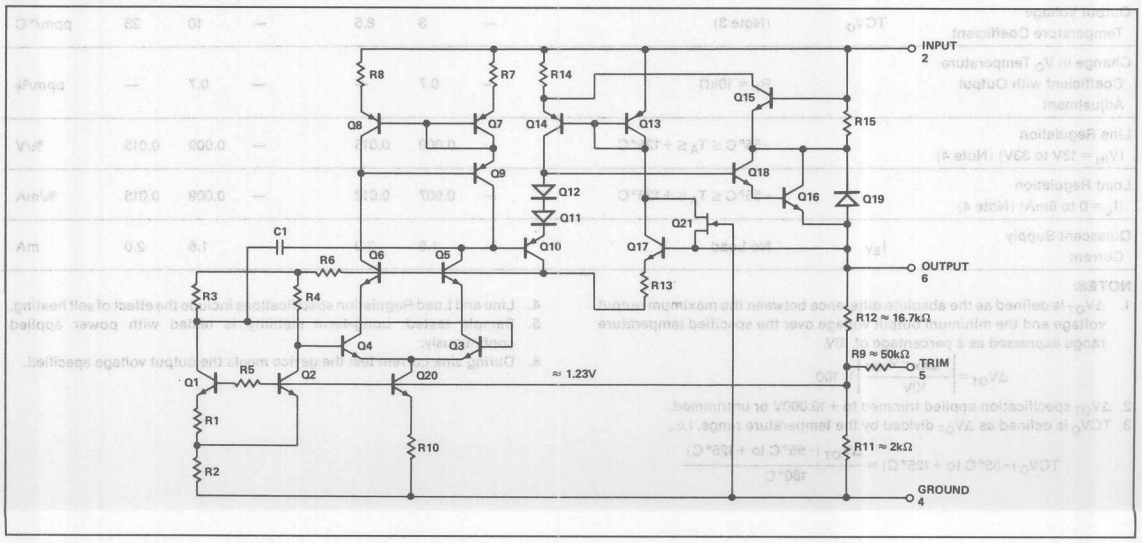
PIN CONNECTIONS & ORDERING INFORMATION



TO-99 (J-Suffix)
REF-10AJ/883
REF-10BJ/883



GENERAL DESCRIPTION

The REF-10 precision voltage reference provides a stable +10V output that can be adjusted over a ±3% range with minimal effect on temperature stability. Long-term drift is guaranteed at 50ppm/1000 hrs. maximum. Single-supply operation over an input voltage range of 12V to 40V, low current drain of 1mA, and excellent temperature stability are achieved with an improved bandgap design. Low cost, low noise, and low power make the REF-10 an excellent choice whenever a stable voltage reference is required. Applications include D/A and A/D converters, portable instrumentation, and digital voltmeters. For +5V precision voltage references, see the REF-05 data sheet.

NOTES:
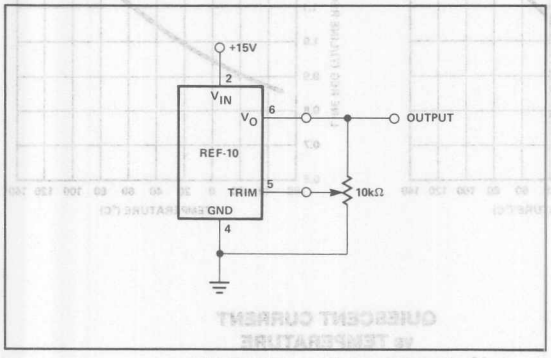
1. ΔV_{OT} is defined as the absolute difference between the maximum output voltage and the minimum output voltage over the specified temperature range expressed as a percentage of 10V.

$$\Delta V_{OT} = \left| \frac{V_{MAX} - V_{MIN}}{10V} \right| \times 100$$

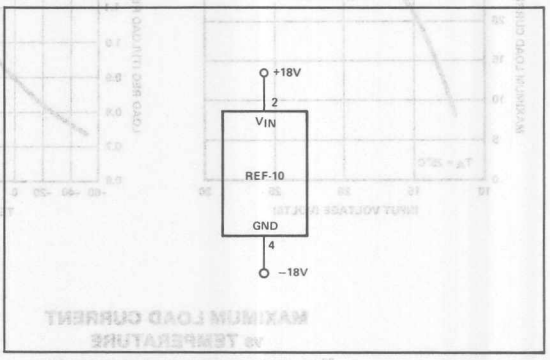
2. ΔV_{OT} specification applied trimmed to +10.000V or untrimmed.
3. TCV_O is defined as ΔV_{OT} divided by the temperature range, i.e.,

$$TCV_O\,(-55°C \text{ to } +125°C) = \frac{\Delta V_{OT}\,(-55°C \text{ to } +125°C)}{180°C}$$



4. Line and Load Regulation specifications include the effect of self heating.
5. Sample tested. Long-term stability is tested with power applied continuously.
6. During sink current test the device meets the output voltage specified.

OUTPUT ADJUSTMENT



The REF-10 trim terminal can be used to adjust the output voltage over a 10V ±300mV range. This feature allows the system designer to trim system errors by setting the reference to a voltage other than 10V. Of course, the output can also be set to exactly 10.000V.

Adjustment of the output does not significantly affect the temperature performance of the device. Typically, the temperature coefficient change is 0.7ppm/°C per 100mV of output adjustment.

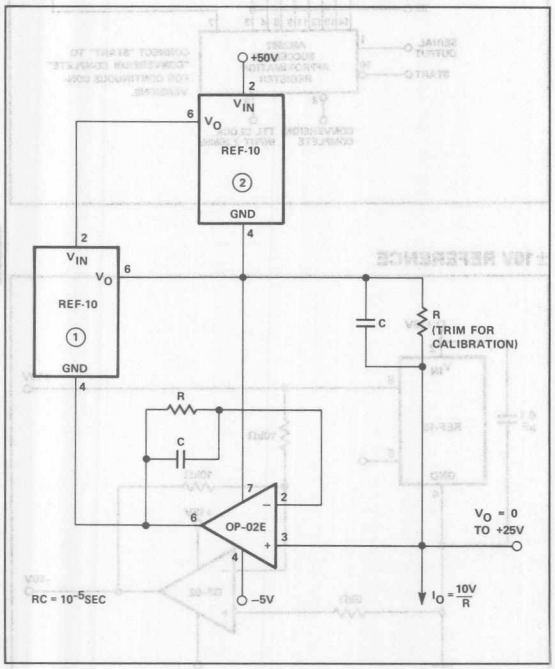
±10V REFERENCE

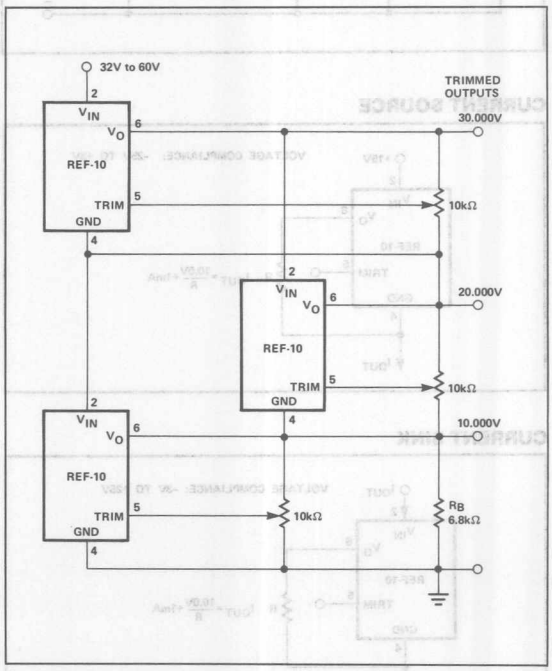


6

PRECISION CURRENT SOURCE

A current source with 25V output compliance and excellent output impedance can be obtained using this circuit. REF-10(2) keeps the line voltage and power dissipation constant in device(1); the only important error consideration at room temperature is the negative supply rejection of the op amp. The typical 3μV/V PSRR of the OP-02E will create an 8ppm change (3μV/V × 25V/10V) in output current over a 25V range. For example, a 10mA current source can be built (R = 1kΩ) with 300 MΩ output impedance.

$$R_O = \frac{25V}{8 \times 10^{-6} \times 10mA}$$



SUPPLY BYPASSING

For best results, it is recommended that the power supply pin is bypassed with a 0.1μF disc ceramic capacitor.

REFERENCE STACK WITH EXCELLENT LINE REGULATION

Three REF-10's can be stacked to yield 10.000, 20.000 and 30.000V outputs. An additional advantage is near-perfect line regulation of the 10.000 and 20.000V output. A 32V to 60V input change produces an output change which is less than the noise voltage of the devices. A load bypass resistor (R_B) provides a path for the supply current (I_{SY}) of the 20.000V regulator.

In general, any number of REF-10's can be stacked this way. For example, ten devices will yield outputs of 10, 20, 30 . . . 100V. The line voltage can range from 105V to 130V. However, care must be taken to ensure that the total load currents do not exceed the maximum usable current (typically 21mA).

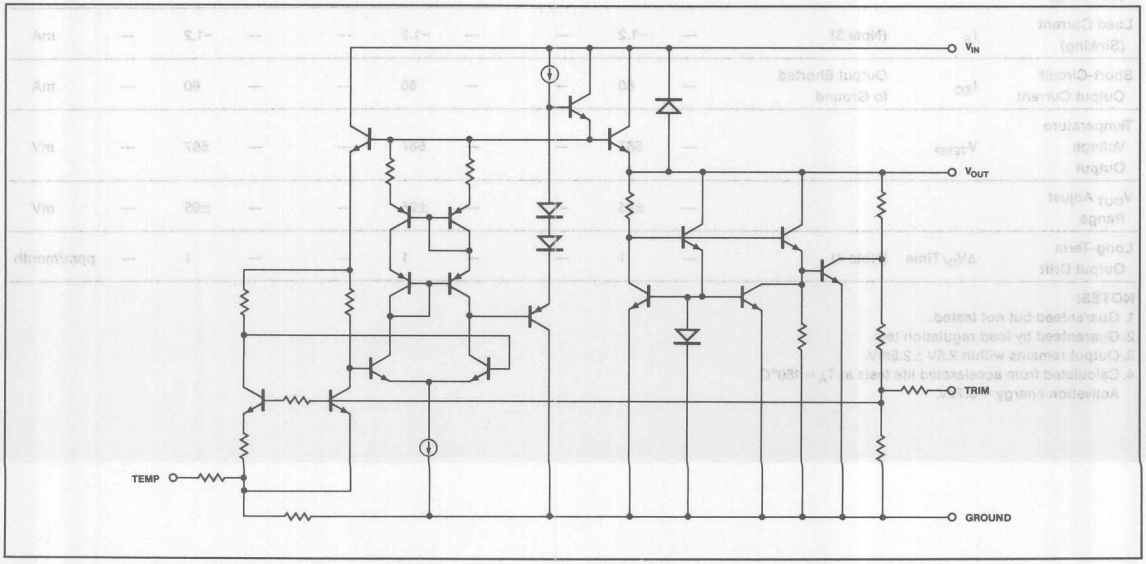
GENERAL DESCRIPTION



The REF-43 is a low-power precision reference providing a stable +2.5V output independent of variations in supply voltage, load conditions or ambient temperature. It is suitable as a reference level for 8, 10 and 12-bit data acquisition systems, or wherever a stable, known voltage is required.

Tight output tolerances and low thermal drift are assured by zener-zap trimming of both output voltage and its temperature coefficient. A unique curvature correction circuit reduces the thermal curvature which is characteristic of many previous bandgap references.

PIN CONNECTIONS

SIMPLIFIED SCHEMATIC

to +40V. The output voltage changes by less than 178μV from one extreme of supply voltage to the other. With only 450μA maximum quiescent current, the REF-43 is ideally suited to applications where power dissipation must be minimized, as in precision battery-powered equipment. The low supply current minimizes drift due to self-heating after power-up.

A temperature output provides a means of determining system ambient temperature. Applications of the REF-43 include A/D and D/A conversion, 4-20mA transmitter/receiver operation, log amplifiers, and power-supply regulators.

For a low-cost 2.5V reference available in small-outline packages consult the REF-03 data sheet.

REF-43 provides a stable +2.5V output voltage with minimal dependence on load current, line voltage or temperature. This voltage is typically used to set an absolute reference point in data conversion circuits, or in analog circuits such as log amps, 4-20mA transmitters and power supplies. The REF-43 is of particular value in systems requiring a high-precision reference using a single +5V supply rail, or where power dissipation must be minimized.

Because an onboard operational amplifier is used to amplify the basic bandgap cell voltage to 2.5V, supply decoupling is critical to the transient performance of a voltage reference. The supply line should be bypassed with a 10μF tantalum capacitor in parallel with a 0.01μF to 0.1μF ceramic capacitor for best results. For less critical conditions, a single 0.1μF capacitor is adequate.

FIGURE 1: Basic Connections

Output decoupling is not generally required or recommended, except to achieve the lowest possible high-frequency output impedance when loads are being switched in and out quickly. As was the case with supply decoupling, best results will be achieved with a 10μF tantalum capacitor in parallel with a 0.01μF to 0.1μF ceramic capacitor. Recommended high-frequency decoupling is shown in Figure 2A, while the transient response of the REF-43 to a sudden 2mA load is shown in Figures 2B and 2C. As can be seen from Figure 2B, if the reference is given 10μs to settle after application or removal of the load, no output decoupling is necessary.

Load regulation is a measure of the DC output impedance of the reference. For the REF-43, this value is specified at 20ppm/mA Max, which is equivalent to only 50 milliohms of output impedance. It is obvious that to truly realize this performance level, wiring resistances from the reference to the rest of the system must be kept as low as is practical.

The REF-43 is capable of delivering at least 10mA to a load. To maintain its precision operation, loads should be kept within the 10mA specification. High-speed testing requires that load regulation is measured on a pulse basis, therefore

High-Frequency Pulse Response

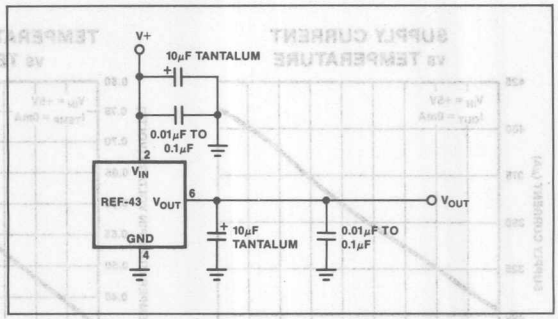

FIGURE 2B: Pulse Response with No Output Decoupling

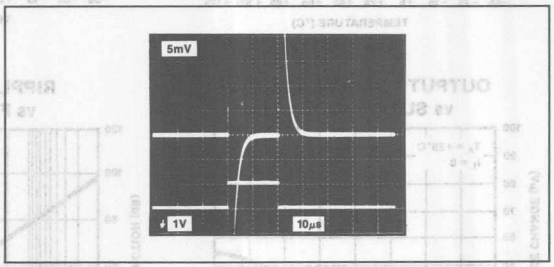

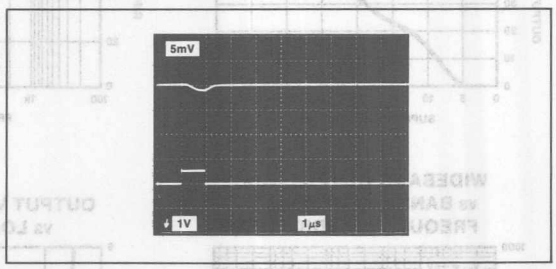

FIGURE 2C: Pulse Response with Output Decoupling

when calculating the output voltage tolerance within a system, the effects of current delivered to the load must be accounted for both as load regulation and as a temperature increase due to power dissipated within the IC. In AC systems, the RMS power dissipation should be used. Thermal effects can be significant since a REF-43 delivering 10mA with an input voltage of 40V must dissipate almost 400mW of power. In the TO-99 package, 400mW of power corresponds to a die temperature increase of 60°C above ambient.

Die temperature is calculated by $T_j = (P_D \times \Theta_{JA}) + T_A$, where P_D is the sum of the power dissipation due to quiescent current and current delivered to the load, $P_D = (I_{SY} \times V_S) + (I_{LOAD} \times (V_S - 2.5V))$. The Θ_{JA} for different packages in a PC board surrounded by free air are listed below.

PACKAGE TYPE	TYP Θ_{JA}(°C/W)
TO-99	150
CERDIP	80
PLASTIC	80
LCC	110

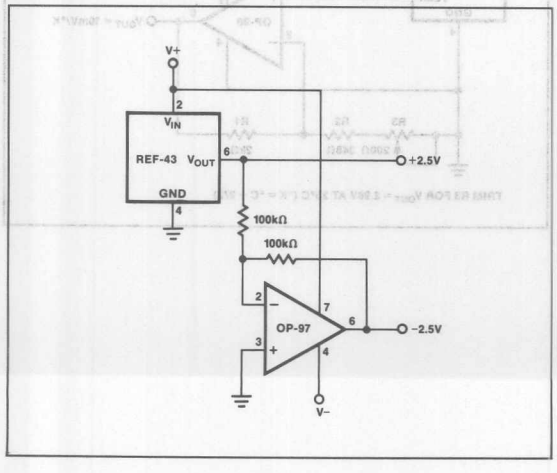
An additional source of error is due to temperature gradients across the package leads, resulting in thermocouple effects. Temperature gradients will be generated when the IC is required to dissipate large amounts of power. Even at low power levels, thermocouple effects may appear as low frequency noise due to air currents across the leads. A significant improvement in low-frequency noise will be found by encasing the reference and any metal junctions such as solder joints (which form thermocouples) along the reference path in a light insulating foam or other enclosure to reduce turbulence. Thermocouple effects can easily add over $10\mu V_{p-p}$ of low-frequency noise.

The temperature output of the REF-43 provides an output voltage which is proportional to the die temperature. When the REF-43 is operating at constant load current, this is a good indication of system temperature. The nominal output voltage at 25°C is 567mV, and the slope is typically 1.9mV/°C(±0.2mV/°C). The TEMP output is affected by the internal trimming done for output voltage tolerance, and will vary between units. If the temperature pin 3 is connected to external circuitry, it should be buffered by an op amp. Current into or out of pin 3 will change the temperature coefficient and curvature of the output voltage, while capacitance at the pin can create instabilities within the reference amplifier.

GENERATING A −2.5V REFERENCE

Often, there is a requirement for a negative reference voltage. The simplest method of generating a −2.5V reference with the REF-43 is to connect an op amp in a gain of −1 to the output, as shown in Figure 3. This provides both positive and negative 2.5V references. Figure 4 shows another method of obtaining a negative reference, in which the current-output

FIGURE 3: ±2.5V Reference



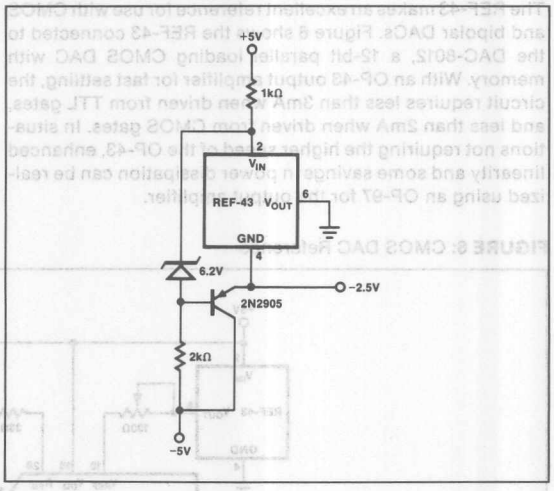


FIGURE 4: −2.5V Reference

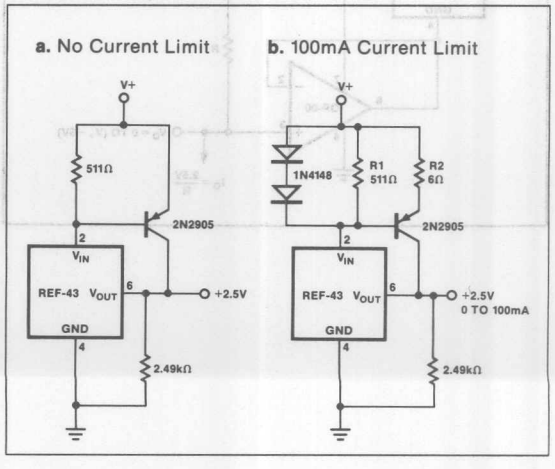

element is a PNP transistor, with the REF-43 in a servo loop to ensure that the output remains 2.5V below ground.

BOOST TRANSISTOR PROVIDES HIGH OUTPUT CURRENT

When applications require more than 10mA current delivery, an external boost transistor may be added to the REF-43 to pass the required current without dissipating excessive power within the IC. The maximum current output to the system is bounded only by the capabilities of the boost transistor. This technique is shown in Figure 5 with and without current limiting. Current limiting may be used to prevent damage to the boost transistor. In Figure 5b, the limit occurs when the voltage dropped across R2 exceeds one V_{BE}(0.6V). The current limit is sensitive to the variations of the diodes' forward drop and the PNP's V_{BE} with temperature, and will decrease with increasing temperature.

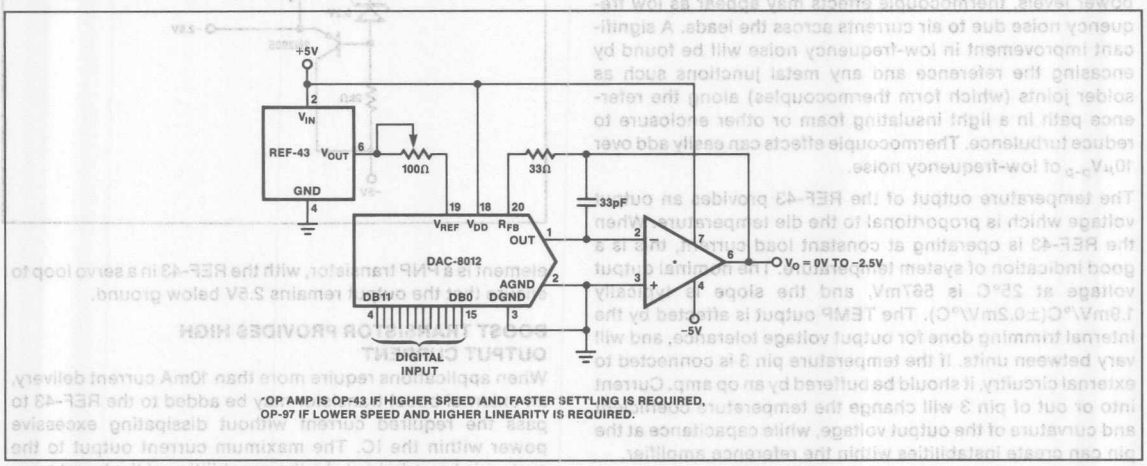

FIGURE 5: Output Current Boost

LOW-POWER CMOS DAC REFERENCE

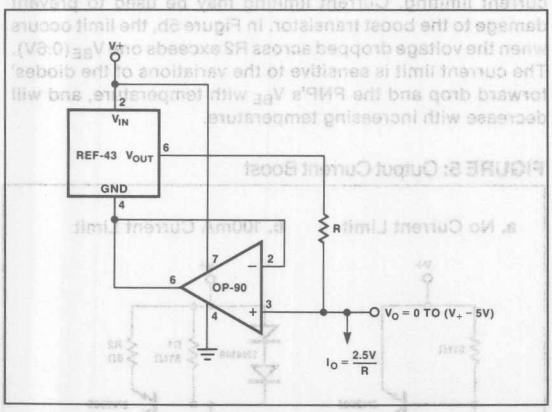
The REF-43 makes an excellent reference for use with CMOS and bipolar DACs. Figure 6 shows the REF-43 connected to the DAC-8012, a 12-bit parallel loading CMOS DAC with memory. With an OP-43 output amplifier for fast settling, the circuit requires less than 3mA when driven from TTL gates, and less than 2mA when driven from CMOS gates. In situations not requiring the higher speed of the OP-43, enhanced linearity and some savings in power dissipation can be realized using an OP-97 for the output amplifier.

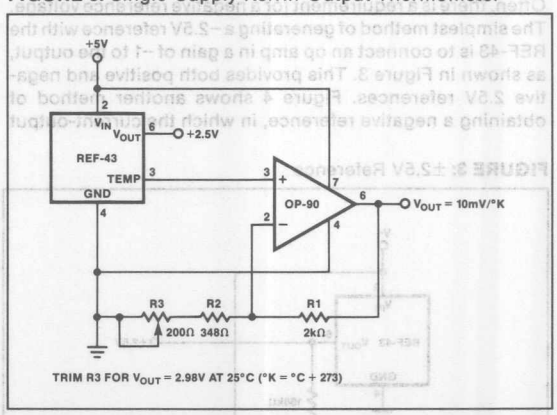
FIGURE 6: CMOS DAC Reference

PRECISION CURRENT SOURCE

Current sources are often required in analog processing and computational circuits. The circuit of Figure 7 shows a high-output-impedance current source capable of single-supply operation. Performance is optimal at current levels below 1mA, since output voltage changes directly affect the power dissipated within the REF-43.

FIGURE 7: Precision Current Source





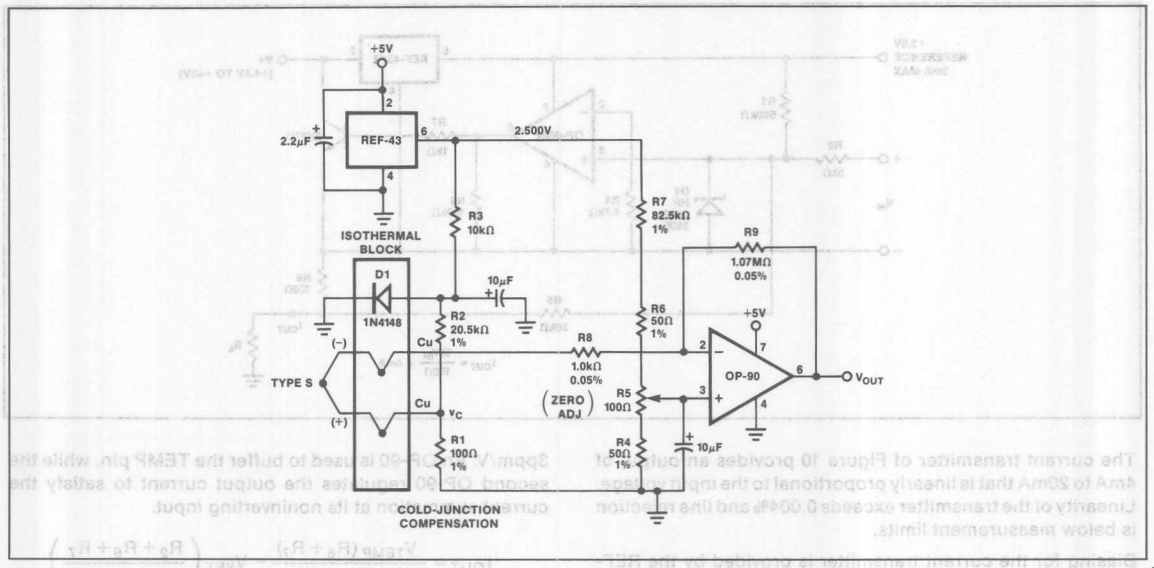


FIGURE 8: Single-Supply Kelvin-Output Thermometer

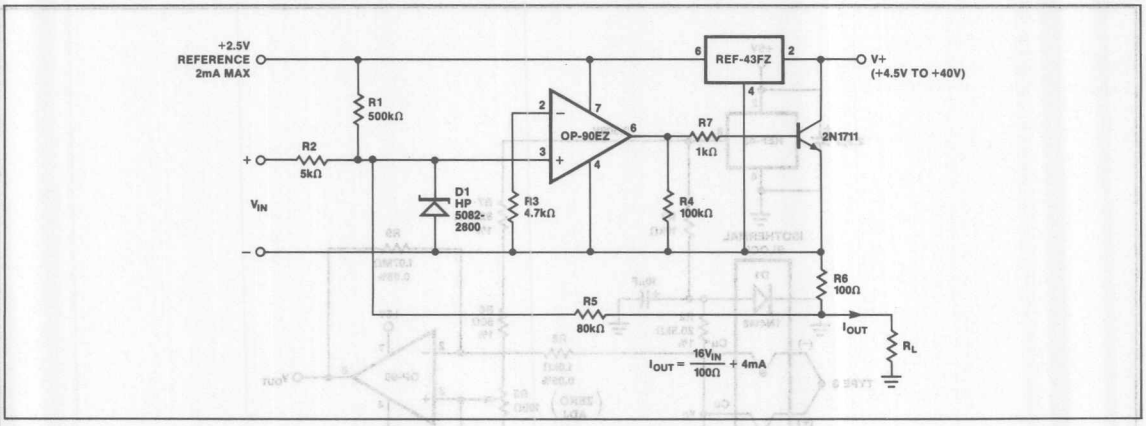
TEMPERATURE MEASUREMENT

Using the REF-43's TEMP output, a Kelvin-output thermometer that operates off a single +5V supply can be built as shown in Figure 8. Since the output of the REF-43's TEMP pin is theoretically zero at 0°K, trimming R3 adjusts both the slope and zero point. In actuality, the ±40mV zero point found by extrapolating the TEMP voltage vs. actual temperature to zero will create a small error. A 4-20mA temperature transmitter is described on page 10 which uses two trims to eliminate this inaccuracy.

For wider temperature ranges than semiconductors can withstand, thermocouples are commonly used. Depending upon the type used, a thermocouple can measure temperatures over 1000°C. Thermocouples require a reference junction, at a known temperature, usually 0°C. Since it is not generally convenient to have an ice bath, electronic methods of simulating this junction have been developed, called cold-junction compensation. In Figure 9, diode D1 is mounted isothermally to the termination of the thermocouple, and along with R1 and R2 provides the cold-junction compensation required for accurate measurement. Using an OP-90 as the amplifier, the circuit will operate off a single +5V supply and is capable of measuring temperatures from 0°C to +400°C. If negative temperatures must be measured, dual supplies must be used to allow the op amp to swing negative. In cases where the electronics are subject to temperature fluctuations, an OP-77 is recommended for its extremely low TCV_{OS}.

Calibration of the thermocouple amplifier is done after a 15 minute warm-up time using R5. A copper wire short is placed across the thermocouple terminating junctions, simulating a 0°C condition. R5 is then adjusted for a 0.00V output. The short is then removed and the amplifier is ready for use. Note that special care must be used in calibration when this circuit is operated single-supply, as the output of the OP-90 will swing to within 500μV of ground, but not below ground. Thus R5 must be trimmed to the point where the output just barely reaches its swing limit.



By changing the appropriate resistor values, the amplifier may be used with type S, J or K thermocouples. In all cases, the output has been scaled with R9 to provide an output of 10mV/°C.

TYPE	SEEBECK COEFFICIENT, α	R1	R2	R7	R9
K	39.2μV/°C	110Ω	5.76kΩ	102kΩ	269kΩ
J	50.2μV/°C	100Ω	4.02kΩ	80.6kΩ	200kΩ
S	10.3μV/°C	100Ω	20.5kΩ	392kΩ	1.07MΩ

TWO-WIRE 4-20mA TRANSMITTERS

4-20mA current loops are used in noisy environments for many types of remote data acquisition. With a two-wire loop, the sensing circuitry can be powered with the same lines used for signal transmission.

FIGURE 10: Two Wire 4-20mA Transmitter

The current transmitter of Figure 10 provides an output of 4mA to 20mA that is linearly proportional to the input voltage. Linearity of the transmitter exceeds 0.004% and line rejection is below measurement limits.

Biasing for the current transmitter is provided by the REF-43FZ. The OP-90EZ regulates the output current to satisfy the current summation at the noninverting node:

$$I_{OUT} = \frac{1}{R6}\left(\frac{V_{IN}\,R5}{R2} + \frac{2.5V\,R5}{R1}\right)$$

For the values shown in Figure 10,

$$I_{OUT} = \left(\frac{16}{100\Omega}\right)V_{IN} + 4mA$$

giving a full-scale output of 20mA with a 100mV input. Adjustment of R2 will provide an offset trim and adjustment of R1 will provide a gain trim. These trims do not interact since the noninverting input of the OP-90 is at virtual ground. The Schottky diode, D1, prevents input voltage spikes from pulling the noninverting input more than 300mV below the inverting input. Without the diode, such spikes could cause phase reversal of the OP-90 and possible latch-up of the transmitter. Compliance of this circuit is from 4.5V to 40V. The voltage reference output can provide up to 2mA for transducer excitation.

The OP-90 is also available in dual and quad versions. Using an OP-490, three of the amplifiers can be used to implement a full instrumentation amplifier for signal conditioning before delivery to the 4-20mA transmitter. All four OP-90s require less than 80μA supply current, and thus have virtually no impact on the current-budget of the 4-20mA loop.

A simple temperature to 4-20mA transmitter is shown in Figure 11. After calibration, the transmitter is accurate to within 1°C over the −50°C to +150°C temperature range. The transmitter operates from +6V to +40V with supply rejection better than 3ppm/V. An OP-90 is used to buffer the TEMP pin, while the second OP-90 regulates the output current to satisfy the current summation at its noninverting input.

$$I_{OUT} = \frac{V_{TEMP}\,(R_6 + R_7)}{R_2\,R_{10}} - V_{SET}\left(\frac{R_2 + R_6 + R_7}{R_2\,R_{10}}\right)$$

The change in output current with temperature is the derivative of the transfer function:

$$\frac{\Delta I_{OUT}}{\Delta T} = \frac{\frac{\Delta V_{TEMP}}{\Delta T}\,(R_6 + R_7)}{R_2\,R_{10}}$$

From the formulas, it can be seen that if the gain trim is adjusted before the final offset trim, the two trims are not interactive, which greatly simplifies the calibration procedure.

To calibrate the transmitter, begin by placing the REF-43 in an ice water (0°C) bath. If necessary, adjust the offset trim, R5, so that the output current is above 4mA.

Record the output current. Next, place the REF-02 in a boiling water (100°C) bath. Adjust the gain trim, R6, so that the change in the output current reflects the desired mA/°C ratio described as follows:

$$\text{Output Ratio} = \frac{\Delta I_{FS}}{\Delta T_{OPERATING}} = \frac{16mA}{\Delta T_{OPERATING}}$$

As an example, assume the transmitter is to operate over the −50°C to +150°C temperature range:

$$\text{Output Ratio} = \frac{16mA}{(150°C - 50°C)} = \frac{16mA}{(200°C)} = 0.08mA/°C$$

If I_{OUT} in the ice water bath equaled 6.3mA, then in the boiling water bath:

$$I_{OUT(100°C)} = I_{OUT(0°C)} + 100°C\ (0.08mA/°C)$$
$$= 6.3mA + 8mA = 14.3mA$$

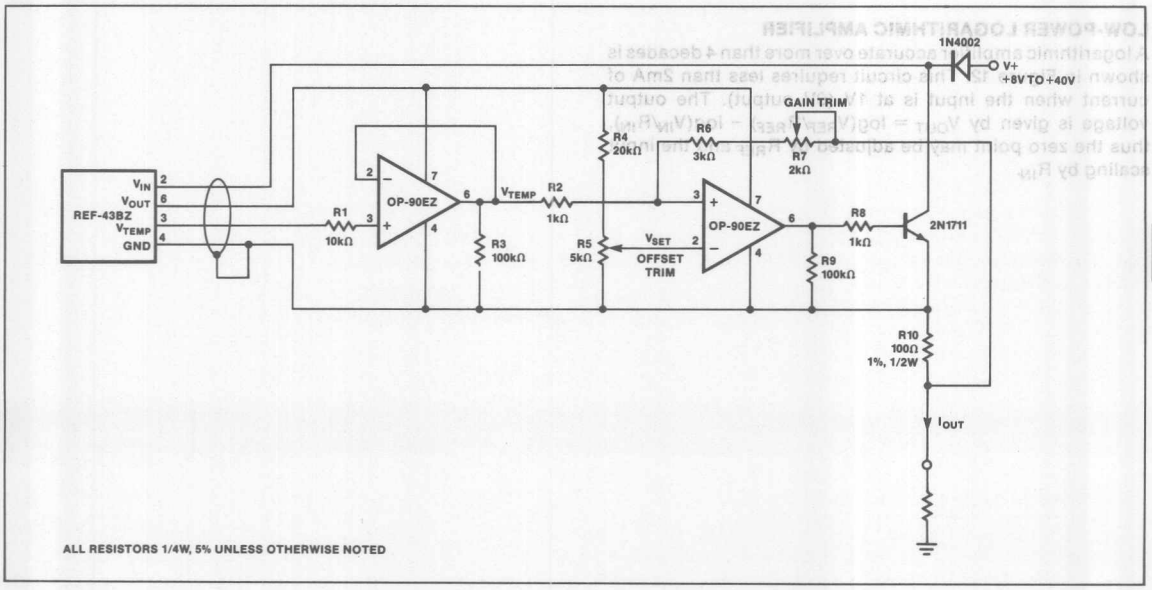
With the REF-43 in the boiling water bath, the gain trim, R6, in this example should be adjusted so I_{OUT} equals 14.3mA.

Once the gain trim has been completed, the offset trim can be made. Remember, that adjusting the offset trim will not affect the gain.

The offset trim can be set at any known temperature by adjusting R5 until the output current equals:

$$I_{OUT} = \left(\frac{\Delta I_{FS}}{\Delta T_{OPERATING}}\right)(T_{AMBIENT} - T_{MIN}) + 4mA$$

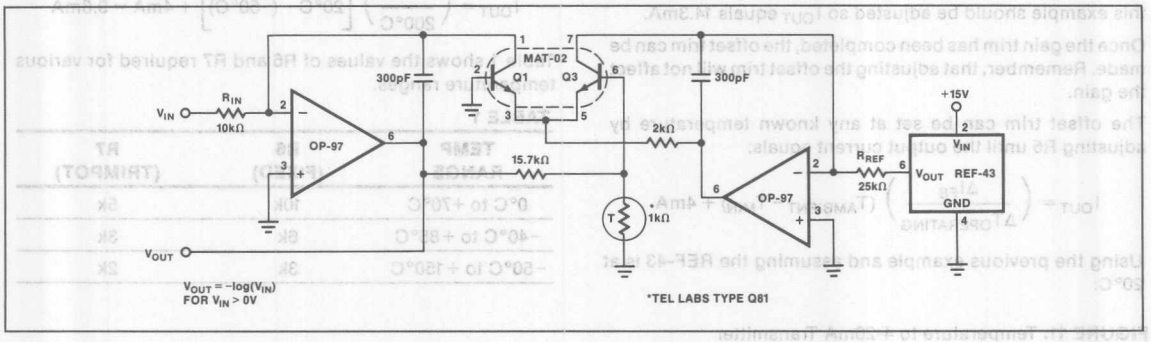
Using the previous example and assuming the REF-43 is at 20°C:



$$I_{OUT} = \left(\frac{16mA}{200°C}\right)\left[20°C - (-50°C)\right] + 4mA = 9.6mA$$

Table 1 shows the values of R6 and R7 required for various temperature ranges.

TABLE 1



TEMP RANGE	R6 (FIXED)	R7 (TRIMPOT)
0°C to +70°C	10k	5k
−40°C to +85°C	6k	3k
−50°C to +150°C	3k	2k

FIGURE 11: Temperature to 4-20mA Transmitter

6

FIGURE 12: Low Power Logarithmic Amplifier

LOW-POWER LOGARITHMIC AMPLIFIER

A logarithmic amplifier accurate over more than 4 decades is shown in Figure 12. This circuit requires less than 2mA of current when the input is at 1V (0V output). The output voltage is given by $V_{OUT} = \log(V_{REF}/R_{REF}) - \log(V_{IN}/R_{IN})$, thus the zero point may be adjusted by R_{REF} and the input scaling by R_{IN}.

Orientation
Data Acquisition Subsystems

Data acquisition subsystems provide many of the functional elements of a complete data acquisition system, in various combinations. By doing this, these subsystems allow complete performance to be provided and specified more easily than with systems built from individual components.

Among the functional blocks that data acquisition subsystems provide are:

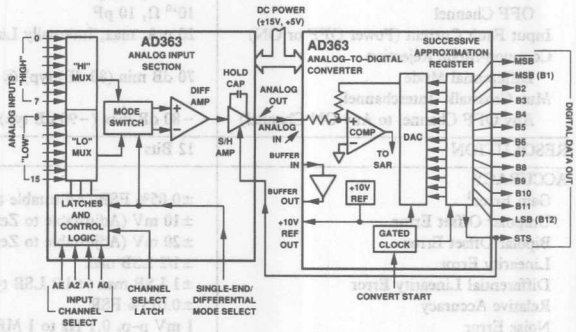
- multiple channel input multiplexer
- programmable gain amplifier
- sample-hold amplifier
- microprocessor interface
- analog-to-digital converter
- converter reference

The data acquisition subsystems detailed on the following pages provide a wide span of performance capabilities. Resolutions of 12, 14, 15, 16 and 20 bits; gain ranges of 64:1 up to 512:1 and throughputs from 300 Hz to 150 kHz are available. These specifications must be compared along with input range, package size, power consumption and linearity to decide which data acquisition subsystem, if any, is best for the application.

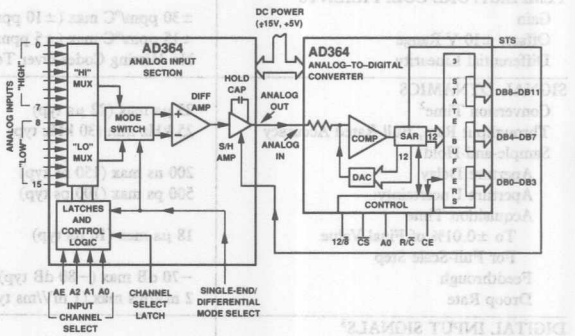
Complete 16-Channel, 12-Bit Data Acquisition Systems

AD363/AD364

FEATURES



AD363



16-Channel Data Acquisition Input Stage with:
- **Digitally Controlled Channel Selection/Mode Control**
- **16 Single-Ended or 8 Differential Channels**
- **25 kHz Throughput Rate**
- **Guaranteed No Missing Codes Over Temperature**

AD364

16-Channel Data Acquisition Input Stage with:
- **Digitally Controlled Channel Selection/Mode Control**
- **16 Single-Ended or 8 Differential Channels**
- **20 kHz Throughput Rate**
- **Guaranteed No Missing Codes Over Temperature**
- **Three-State Buffered Digital Output**

FUNCTIONAL BLOCK DIAGRAMS

PRODUCT DESCRIPTIONS

The AD363 and AD364 are complete 16-channel data acquisition systems which condition and subsequently convert an analog voltage into digital form. Each system consists of two devices, an analog input stage (AIS) and an analog-to-digital converter (ADC). The AIS includes a two 8-channel multiplexers, a channel address register, a unity gain instrumentation amplifier, and a sample-hold amplifier. The multiplexers may be connected to the instrumentation amplifier in either an 8-channel differential or 16-channel single ended configuration. A unique feature of these products is an internal user controlled switch which connects the multiplexers in either single-ended or differential mode. This allows a single device to perform in either mode with hard-wire programming and permits interfacing a mixture of single-ended and differential signals by dynamically switching the input mode control.

The AD363 and AD364 differ in ADC performance. Each ADC is a complete 12-bit successive approximation converter including an internal clock and a precision reference. Active laser trimming results in maximum linearity errors of ±0.012% with conversion times of 25 μs (AD363) or 32 μs (AD364). The hybrid AD363-ADC has five user selectable input ranges (±2.5, ±5.0, ±10.0, 0 to +5, and 0 to +10 volts) and includes a high impedance buffer amplifier. The AD364-ADC is a monolithic converter with 3-state output buffer circuitry for direct interface to an 8-, 12-, or 16-bit processor bus and three user selected input ranges (±5, ±10, and 0 to +10 volts).

Both products are specified for operation over both the commercial (0°C to +70°C) and military (−55°C to +125°C) temperature ranges. The AD363 and AD364 are available with environmental screening. Please contact the factory or nearest sales office for details.

AD363/AD364—SPECIFICATIONS (typical @ +25°C, ±15 V and +5 V unless otherwise noted)

Parameter	AD363RK	AD363RS
ANALOG INPUTS		
Number of Inputs	16 Single-Ended or 8 Differential (Electronically Selectable)	*
Input Voltage Ranges		
Bipolar	±2.5 V, ±5.0 V, ±10.0 V	*
Unipolar	0 to +5 V, 0 to +10 V	*
Input (Bias) Current, per Channel	±50 nA max	*
Input Impedance		
ON Channel	10^{10} Ω, 100 pF	*
OFF Channel	10^{10} Ω, 10 pF	*
Input Fault Current (Power OFF or ON)	20 mA, max, Internally Limited	*
Common-Mode Rejection		
Differential Mode	70 dB min (80 dB) typ) @ 1 kHz, 20 V p–p	*
Mux Crosstalk (Interchannel,		
Any OFF Channel to Any ON Channel)	−80 dB max (−90 dB typ) @ 1 kHz, 20 V p–p	*
RESOLUTION	12 Bits	*
ACCURACY		
Gain Error[1]	±0.05% FSR (Adjustable to Zero)	*
Unipolar Offset Error	±10 mV (Adjustable to Zero)	*
Bipolar Offset Error	±20 mV (Adjustable to Zero)	*
Linearity Error	±1/2 LSB max	*
Differential Linearity Error	±1 LSB max (±1/2 LSB typ)	*
Relative Accuracy	±0.025% FSR	*
Noise Error	1 mV p–p, 0.1 Hz to 1 MHz	*
TEMPERATURE COEFFICIENTS		
Gain	±30 ppm/°C max (±10 ppm/°C typ)	±25 ppm/°C max (±15 ppm/°C typ)
Offset, ±10 V Range	±15 ppm/°C max (±5 ppm/°C typ)	±8 ppm/°C max (±5 ppm/°C typ)
Differential Linearity	No Missing Codes Over Temperature Range	*
SIGNAL DYNAMICS		
Conversion Time[2]	25 µs max (22 µs typ)	*
Throughput Rate, Full Rated Accuracy	25 kHz min (30 kHz typ)	*
Sample-and-Hold		
Aperture Delay	200 ns max (150 ns typ)	*
Aperture Uncertainty	500 ps max (100 ps typ)	*
Acquisition Time		
To ±0.01% of Final Value	18 µs max (10 µs typ)	*
For Full-Scale Step		
Feedthrough	−70 dB max (−80 dB typ) @ 1 kHz	*
Droop Rate	2 mV/ms max (1 mV/ms typ)	*
DIGITAL INPUT SIGNALS[3]

AIS Functional Block Diagram

DESIGN

Concept

Figures 1 and 2 show a general DAS application using the AD363 and AD364, respectively.

By dividing the data acquisition task into two sections, several important advantages are realized. Performance of each design is optimized for its specific function. Production yields are increased thus decreasing costs. Furthermore, the standard configuration packages plug into standard sockets and are easier to handle than larger packages with higher pin counts.

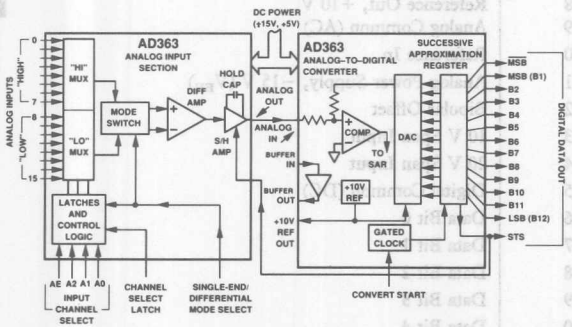

Figure 1. AD363 DAS

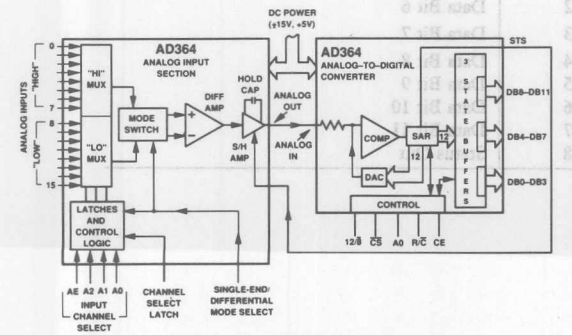

Figure 2. AD364 DAS

Figures 1 and 2 operating at the maximum conversion rate.

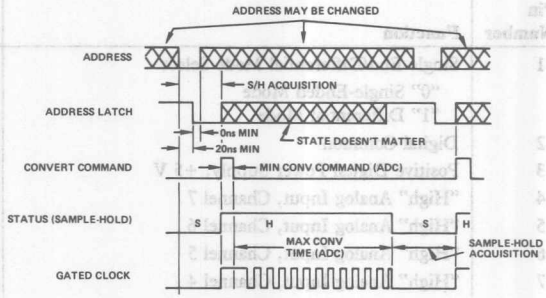

Figure 3. AD363 Timing Diagram

The normal sequence of events is as follows:

1. The appropriate Channel Select Address is latched into the address register. Time is allowed for the multiplexers to settle.
2. A Convert Start command is issued to the ADC which, in response, indicates that it is "busy" by placing a Logic "1" on its Status line.
3. The ADC Status controls the sample-and-hold. When the ADC is "busy," the sample-and-hold is the Hold mode.
4. The ADC goes into its conversion routine. Since the sample-and-hold is holding the proper analog value, the address may be updated during conversion. Thus multiplexer settling time can coincide with conversion and need not affect throughput rate.
5. The ADC indicates completion of its conversion by returning Status to Logic "0." The sample-and-hold returns to the Sample mode.
6. If the input signal has changed full scale (different channels may be widely varying data) the sample-and-hold will typically require 10 microseconds to"acquire" the next input to sufficient accuracy for 12-bit conversion.

After allowing a suitable interval for sample-and-hold to stabilize at its new value, another Convert Start command may be issued to the ADC.

AD363-ADC OPERATION

Figure 4 shows a detailed timing diagram for the AD363-ADC. Serial data changes on rising edges of the internal clock and is guaranteed to be stable on falling edges.

AD364-ADC OPERATION

There are two sets of control pins on the AD364-ADC: the general control inputs (CE, $\overline{CS}$, and R/$\overline{C}$) and the internal register controls inputs (12/$\overline{8}$ and A_O). The general control pins function similarly to those on most A/D converters, performing device timing, addressing, cycle initiation, and read enable functions. The internal register control inputs, which are not found on most A/D converters, select output data format and conversion cycle length.

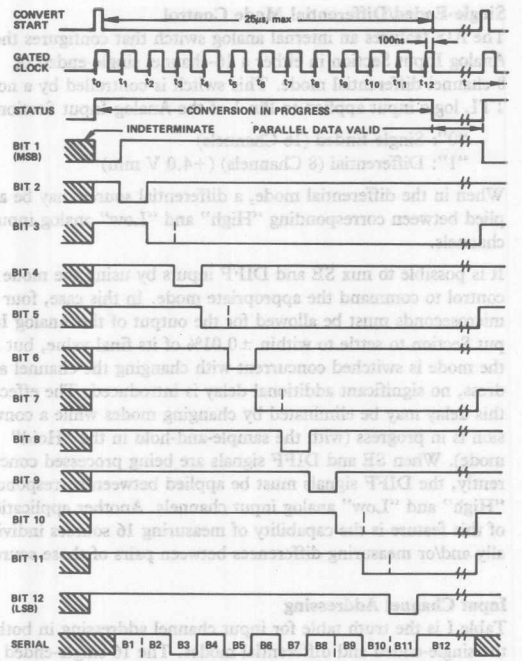

Figure 4. AD363-ADC Timing Diagram (Binary Code 110101011001)

The two major control functions, convert start and read enable, are controlled by CE, $\overline{CS}$, and R/$\overline{C}$. Although all three inputs must be in the correct state to perform the function (for convert start, CE = 1, $\overline{CS}$ = 0, R/$\overline{C}$ = 0; for read enable, CE = 1, $\overline{CS}$ = 0, R/$\overline{C}$ = 1), the sequence does not matter. For large systems, typically microprocessor controlled, standard operation for convert start would be to first set R/$\overline{C}$ = 0 (from R/$\overline{W}$ line); address the chip with $\overline{CS}$ = 0, then apply a positive start pulse to CE. A read would be done similarly but with R/$\overline{C}$ = 1.

A_O (byte select) and 12/$\overline{8}$ (data format) inputs work together to control the output data and conversion cycle. In almost all situations 12/$\overline{8}$ is hard-wired "high" (to V_{LOGIC}) or "low" (to Digital Common). If it is wired high, all 12 data lines will be enabled when the read function is called by the general control inputs. For an 8-bit bus interface, 12/$\overline{8}$ will be wired low. In this mode, only the 8 upper bits or the 4 lower bits can be enabled at once, as addressed by A_O. For these applications, the 4 LSBs (Pins 16–19) should be hard-wired to the 4 MSB (Pins 24–27). Thus, during a read, when A_O is low, the upper 8 bits are enabled and present data on Pins 20 through 27. When A_O goes high, the upper 8 data bits are disabled, the 4 LSBs then present data to Pins 24 to 27, and the 4 middle bits are overridden so that zeros are presented to Pins 20 through 23.

The A_O input performs an additional function of controlling conversion length. If A_O is held low prior to cycle initiation, a full 12-bit, 25 μs cycle will result; if A_O is held high prior to cycle initiation, a shortened 8-bit, 16 μs cycle will result. The A_O line must be set prior to cycle initiation and held in the desired position at least until STS goes high. Thus, for microprocessor interface applications, the A_O line must be properly controlled during both the convert start and read functions.

STANDARD FULL CONTROL INTERFACE

The timing for the standard full control interface is shown in Figure 5. In this operating mode, $\overline{CS}$ is used as the address input which selects the particular device, R/$\overline{C}$ selects between the read data and start conversion functions, and CE is used to time the actual functions.

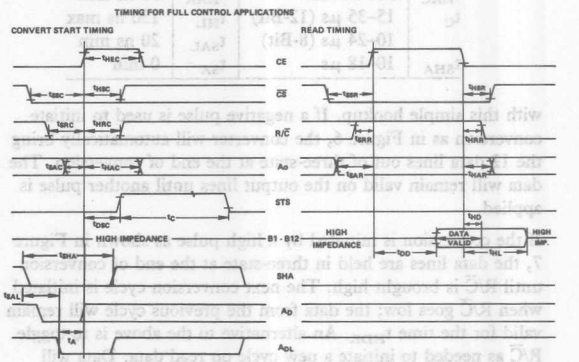

Figure 5. AD364-ADC Timing Diagram

The left side of the figure shows the conversion start control. $\overline{CS}$ and R/$\overline{C}$ are brought low (their sequence does not matter), then the start pulse is applied to CE. The timing diagram shows a time delay for $\overline{CS}$ and R/$\overline{C}$ prior to the start pulse at CE. If less time than this is allowed, the conversion will still be started, but an appropriately longer pulse will be needed at CE. However, if the hold times for $\overline{CS}$ and R/$\overline{C}$ after the rising edge of the start pulse at CE are not followed, the conversion may not be initiated.

The A_O line determines the conversion cycle length and must be selected prior to conversion initiation. If A_O is low, a 12-bit cycle results; if A_O is high, an 8-bit short cycle results. Minimum setup and hold times are shown. The status line goes high to indicate conversion in progress. The analog input signal is allowed to vary until the STS goes high. It must then be held steady until STS again goes low at the end of conversion.

The data read function operates in a similar fashion except that R/$\overline{C}$ is now held high. The data is stored in the output register and can be recalled at will until a new conversion cycle is commanded. In addition, if the converter is arranged in the 8-bit data mode, the A_O line now functions as the byte select address, with setup and hold times as shown. With A_O low, Pins 20 to 27 (DB4–11) come out of three-state and present data. With A_O high, Pins 16–19 (DB0–3) come out of three-state with data and Pins 20–23 present active trailing zeros. In the 8-bit mode, Pins 16–19 will be hard-wired directly to Pin 24–27 for direct two byte loading onto an 8-bit bus. There are two delay times for the data lines after CE is brought low: t_{HD} is the delay until the outputs are fully into the high impedance state.

STANDALONE OPERATION

For simpler control functions, the AD364-ADC can be controlled with just R/$\overline{C}$. In this case, CE is wired high, $\overline{CS}$ low, 12/$\overline{8}$ high, and A_O low. There are two ways of cycling the device

	10–24 μs (8-Bit)	t_{SAL}	20 ns min
t_{SHA}	10–18 μs	t_{SA}	0 min

with this simple hookup. If a negative pulse is used to initiate conversion as in Figure 6, the converter will automatically bring the 12 data lines out of three-state at the end of conversion. The data will remain valid on the output lines until another pulse is applied.

If the conversion is initiated by a high pulse as shown in Figure 7, the data lines are held in three-state at the end of conversion until R/$\overline{C}$ is brought high. The next conversion cycle is initiated when R/$\overline{C}$ goes low; the data from the previous cycle will remain valid for the time t_{HDR}. An alternative to the above is to toggle R/$\overline{C}$ as needed to initiate a new cycle on read data. Data will appear when R/$\overline{C}$ is brought high, a new cycle is initiated when R/$\overline{C}$ goes low.

APPLICATIONS

Single-Ended/Differential Mode Control

The AIS features an internal analog switch that configures the Analog Input Section in either a 16-channel single-ended or 8-channel differential mode. This switch is controlled by a non-TTL logic input applied to Pin 1 of the Analog Input Section:

"0": Single-Ended (16 Channels)
"1": Differential (8 Channels) (+4.0 V min)

When in the differential mode, a differential source may be applied between corresponding "High" and "Low" analog input channels.

It is possible to mix SE and DIFF inputs by using the mode control to command the appropriate mode. In this case, four microseconds must be allowed for the output of the Analog Input Section to settle to within ±0.01% of its final value, but if the mode is switched concurrent with changing the channel address, no significant additional delay is introduced. The effect of this delay may be eliminated by changing modes while a conversion is in progress (with the sample-and-hold in the "Hold" mode). When SE and DIFF signals are being processed concurrently, the DIFF signals must be applied between corresponding "High" and "Low" analog input channels. Another application of this feature is the capability of measuring 16 sources individually and/or measuring differences between pairs of those sources.

Input Channel Addressing

Table I is the truth table for input channel addressing in both the single-ended and differential modes. The 16-single-ended channels may be addressed by applying the corresponding digital number to the four Input Channel Select address bits, AE, A0, A1, A2 (Pins 28–31). In the differential mode, the eight channels are addressed by applying the appropriate digital code to A0, A1, and A2; AE must be enabled with a Logic "1." Internal logic monitors the status of the SE/DIFF Mode input and addresses the multiplexers singularly or in pairs as required.

ADDRESS				ON CHANNEL (Pin Number)		
					Differential	
AE	A2	A1	A0	Single-Ended	"Hi"	"Lo"
0	0	0	0	0 (11)	None	
0	0	0	1	1 (10)	None	
0	0	1	0	2 (9)	None	
0	0	1	1	3 (8)	None	
0	1	0	0	4 (7)	None	
0	1	0	1	5 (6)	None	
0	1	1	0	6 (5)	None	
0	1	1	1	7 (4)	None	
1	0	0	0	8 (27)	0 (11)	0 (27)
1	0	0	1	9 (26)	1 (10)	1 (26)
1	0	1	0	10 (25)	2 (9)	2 (25)
1	0	1	1	11 (24)	3 (8)	3 (24)
1	1	0	0	12 (23)	4 (7)	5 (23)
1	1	0	1	13 (22)	5 (6)	5 (22)
1	1	1	0	14 (19)	6 (5)	6 (19)
1	1	1	1	15 (18)	7 (4)	7 (18)

Table I. Input Channel Addressing Truth Table

When the channel address is changed, six microseconds must be allowed for the Analog Input Section to settle to within ±0.01% of its final output (including settling times of all elements in the signal path). The effect of this delay may be eliminated by performing the address change while a conversion is in progress (with the sample-and-hold in the "hold" mode). All unused inputs must be grounded.

Input Channel Address Latch

The AIS is equipped with a latch for the Input Channel Select address bits. If the Latch Control pin (Pin 32) is at Logic "1," input channel select address information is passed through to the multiplexers. A Logic "0" "freezes" the input channel address present at the inputs at the "1"-to-"0" transition level-triggered.

This feature is useful when input channel address information is provided from an address, data or control bus that may be required to service many devices. The ability to latch an address is helpful whenever the user has no control of when address information may change.

Sample-and-Hold Mode Control

The Sample-and-Hold Mode Control input (Pin 13) is normally connected to the Status output (Pin 20) from an analog-to-digital converter. When a conversion is initiated by applying a Convert Start command to the ADC, Status goes to Logic "1," putting the sample-and-hold in to the "Hold" mode. This "freezes" the information to be digitized for the period of conversion. When the conversion is complete, Status returns to Logic "0" and the sample-and-hold returns to the "Sample" mode. Eighteen microseconds must be allowed for the sample-and-hold to acquire ("catch up" to) the analog input to within ±0.01% of the final value before a new Convert Start command is issued.

The purpose of a sample-and-hold is to "stop" fast changing input signals long enough to be converted. In this application, it also allows the user to change channels and/or SE/DIFF mode while a conversion is in progress thus eliminating the effects of multiplexer, analog switch and differential amplifier settling times. If maximum throughput rate is required for slowly changing signals, the Sample-and-Hold Mode Control may be wired to ground (Logic "0") rather than to ADC Status thus leaving the sample-and-hold in a continuous sample mode.

Analog Input Section Offset Adjust Circuit

Although the offset voltage of the AIS may be adjusted, that adjustment is normally performed at the ADC. In some special applications, however, it may be helpful to adjust the offset of the Analog Input Section. An example of such a case would be if the input signals were small (<10 mV) relative to the AIS voltage offset and if a gain stage was to be inserted between the AIS and the ADC. To adjust the offset of the AIS, the circuit shown in Figure 8 is recommended.

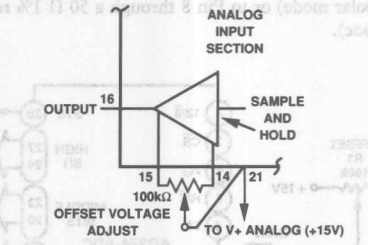

Figure 8. AIS Offset Voltage Adjustment

Under normal conditions, all calibration is performed at the ADC Section.

Gain Adjust, AD363-ADC: Gain may be adjusted by connecting a 100 Ω potentiometer between +10 V Reference Output and Gain Adjust Input (ADC Pins 18 and 27). A multi-turn, low temperature coefficient potentiometer, such as a 20-turn cermet device, is recommended. This potentiometer may be replaced with a 50 Ω, 0.1% resistor to obtain an absolute gain calibration of 0.05% without trimming.

Offset Adjust, AD363-ADC: The simplest offset adjust circuit requires a 20-turn, 20 kΩ cermet potentiometer and a 3.9 MΩ resistor as shown in Figure 9a. This arrangement has an adjustment range of ±8 LSBs, and will contribute a maximum of 2.3 ppm/°C offset drift with a carbon composition fixed resistor (TC = −1200 ppm/°C). Drift contributions from the offset adjust circuit can be reduced well below this level using metal-film resistors and the circuit of Figure 9b.

Gain Adjust, AD364-ADC: Gain may be adjusted by connecting a 100 Ω potentiometer between the Reference Output and Reference Input (ADC Pins 8 and 10). A multi-turn, low temperature coefficient potentiometer, such as a 20T cermet device, is recommended. A fixed 50 Ω, 1% resistor should be connected between Pins 8 and 10 if no gain trim is required.

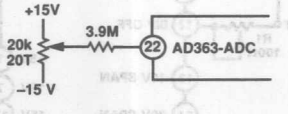

Figure 9a.

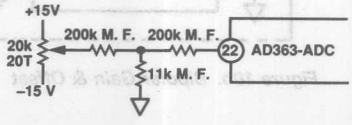

Figure 9b.

Offset Adjust, AD364-ADC: Offset adjust circuits for unipolar and bipolar operation are shown in Figures 10a and 10b. In each case the potentiometer should be a multi-turn, low temperature coefficient device, such as 20-turn cermet. Lowest offset drift in unipolar operation will be realized when the fixed resistors are low-TC (100 ppm/°C) metal-film types.

(bipolar mode).

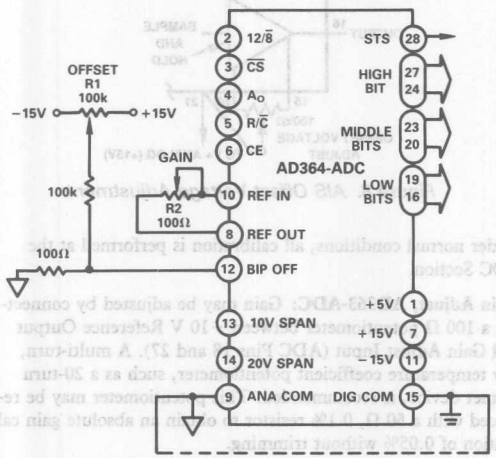

Figure 10a. Unipolar Gain & Offset

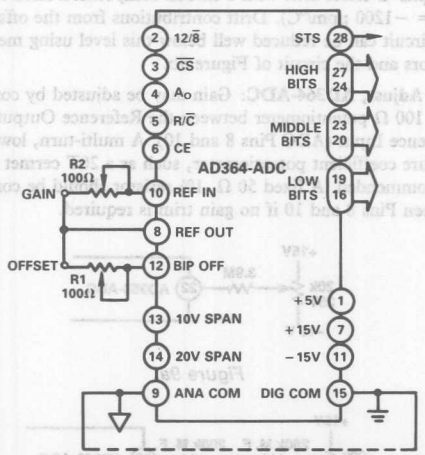

Figure 10b. Bipolar Gain & Offset

Input Scaling: Connections for the various ADC input ranges are given in Tables II and III.

Buffer: An uncommitted unity-gain buffer is available in the AD363-ADC. This buffer has a 2 μs settling time to 0.01% for a 20 V step. Its input should be grounded if the buffer is not used.

Range	Input To Pin:	Span Pin:	Pin 23 To:
0 to +5 V	24	25 to 22	22
0 to +10 V	24	—	
−2.5 V to +2.5 V	24	25 to 22	
−5 V to +5 V	24	—	
−10 V to +10 V	25	—	

Table II. AD364-ADC Pin Connections

Range	Connect Analog Input To Pin:	Connect Pin 12 To:
0 to +10 V	13	GND*

−10 V to +10 V	14	Pin 8**

*Refer to Figure 10a for gain and offset adjustments.
**Refer to Figure 10b for gain and offset adjustments.

Table III. AD364-ADC Pin Connections

Other Considerations

Grounding: Analog and digital signal grounds should be kept separate where possible to prevent digital signals from flowing in the analog ground circuit and inducing spurious analog signal noise. Analog Ground (Pin 17) and Digital Ground (Pin 2) are not connected internally; these pins must be connected externally for the system to operate properly. Preferably, this connection is made at only one point, as close to the AIS, as possible. The case is connected internally to Digital Ground to provide good electrostatic shielding. If the grounds are not tied common on the same card with the AIS they should be connected with back-to-back general purpose diodes as shown in Figure 11. This will protect the AIS from possible damage caused by voltages in excess of ±1 volt between the ground systems which could occur if the key grounding card should be removed from the overall system. The device will operate properly with as much as ±200 mV between grounds, however this difference will be reflected directly as an input offset voltage.

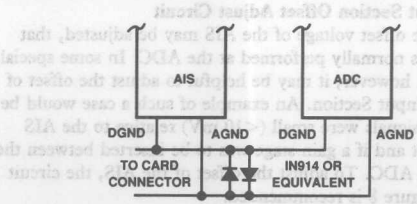

Figure 11. Ground-Fault Protection Diodes

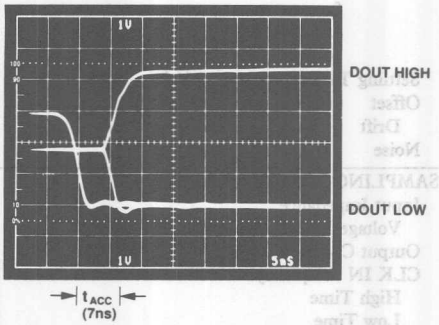
Power Supply Bypassing: The ±15 V and +5 V power leads should be capacitively bypassed to Analog Ground and Digital Ground respectively for optimum device performance. 1 μF tantalum types are recommended; these capacitors should be located close to the system. It is not necessary to shunt these capacitors with disc capacitors to provide additional high frequency power supply decoupling since each power lead is bypassed internally with a 0.039 μF ceramic capacitor.

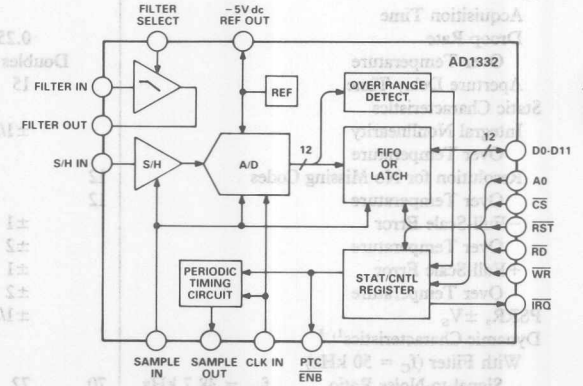
Complete 12-Bit Sampling A/D Converter for Digital Signal Processing

AD1332

FEATURES



Complete A/D System for DSP Includes:
- 4th Order Antialiasing Filter
- 12-Bit Sampling A/D Converter
- 32-Word FIFO Memory
- Fully Asynchronous, High Speed Digital Interface



Sample Rate up to 125 kHz
Entire System Is Dynamically Specified
15 ns Data Access Time Allows "No Wait State" Interface to: ADSP-2100 (A), TMS320C25 DSP56000, NECμPD77230

APPLICATIONS

Sonar Signal Processing
Vibration Analysis
Ultrasound Imaging
PC Data Acquisition
High Speed Modems
Motion Control
Speech Processing

DATA ACCESS TIME
(Typical at +25°C)

AD1332 Block Diagram

PRODUCT DESCRIPTION

The AD1332 is a complete, 12-bit A/D converter system optimized for use in high speed digital signal processing (DSP) applications. The device consists of a fourth order antialiasing filter, a 12-bit sampling A/D, a fully asynchronous high speed digital interface and a 32-word FIFO memory. The AD1332 is manufactured using highly reliable advanced hybrid circuit assembly techniques and is packaged in a 40-pin hermetic DIP.

The antialiasing filter is an active four-pole Butterworth. Cutoff frequencies (f_C) are user-selectable (capacitor programmable), and operation is specified for f_C up to 50 kHz. The filter may be bypassed entirely if desired.

The 12-bit sampling A/D converter can convert ±5 V full-scale signals at sample rates up to 125 kHz. The rate is programmable by means of a single external clock. The entire converter system is specified and tested for signal-to-noise ratio and total harmonic distortion.

The digital interface provides a true asynchronous link between the A/D and a high speed microprocessor. Data transfer is controlled by generating an interrupt signal when data is available. Interrupts can be generated when the FIFO is full (32 words), half-full (16 words), or when a single word of data is ready (FIFO bypassed). In addition, the AD1332 can generate an interrupt signal when the A/D conversion results are overrange.

The AD1332 provides a completely specified and tested system that bridges the interface and specification gap between A/D converters and high speed DSP.

This is an abridged version of the data sheet. To obtain a complete data sheet, contact your nearest sales office.

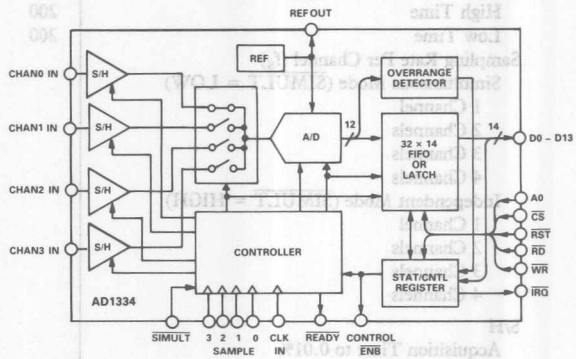
*Stresses greater than those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. This is a stress rating only and functional operation of the device at these or any other conditions above those indicated in the operational section of this specification is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

CAUTION

ESD (electrostatic discharge) sensitive device. The digital control inputs are diode protected; however, permanent damage may occur on unconnected devices subject to high energy electrostatic fields. Unused devices must be stored in conductive foam or shunts. The protective foam should be discharged to the destination socket before devices are removed.

Four-Channel 12-Bit Sampling A/D Converter for Digital Signal Processing

AD1334



FEATURES

- Four-Channel A/D Converter for DSP Includes:
  - Simultaneous or Independent Sampling Capability
  - 12-Bit Accurate A/D Converter
  - 2-Bit Channel ID Tags Each Conversion Result
  - 32-Word FIFO Memory
  - Fully Asynchronous, High Speed Digital Interface
- Single-Channel Sample Rate Up to 67 kHz
- Four-Channel Simultaneous Sample Rate Up to 28 kHz
- Entire System Dynamically Characterized
- Minimal Effective Aperture Delay Mismatch from Channel-to-Channel & Device-to-Device
- 15 ns Data Access Time Allows "No Wait State" Interface to: ADSP-2100 (A), TMS320C25 DSP56000, NECμPD77230
- Low Power, 250 mW/Channel

APPLICATIONS

- Sonar Signal Processing
- Robotics/Machine Control
- Disk-Drive Head Positioning
- Vibration Analysis

BLOCK DIAGRAM

PRODUCT DESCRIPTION

The AD1334 is a four-channel, 12-bit, sampling A/D converter system optimized for use in multichannel digital signal processing (DSP) applications. The device consists of four independent sample-and-hold amplifiers, a multiplexer, an A/D converter, a controller, a 32-word FIFO memory and a fully asynchronous high speed digital interface. The product is packaged in a 40-pin hermetic DIP.

The channel controller enables the AD1334 to appear as four independent channels of analog input by generating all of the timing necessary to ensure that the sampled channel is digitized to 12-bit accuracy. Upon receipt of a sample command, the controller will immediately place the sample-and-hold amplifier into hold mode and then prioritize and schedule the held value for A/D conversion. At the appropriate time, the sampled input is gated through the multiplexer and, after settling, is digitized by the A/D converter. The sample-and-hold amplifier is then returned to sample mode so that it can acquire the next sample.

For effective use in simultaneous sampling applications, the sample-and-hold amplifiers are designed to provide a minimum amount of aperture delay time mismatch from channel-to-channel and device-to-device.

The 12-bit A/D converter can convert ±5 V full scale signals at sample rates up to 67 kHz for single-channel operation. In the simultaneous mode, the AD1334 has a four-channel sample rate up to 28 kHz. The entire converter system is specified and tested for signal-to-noise ratio, total harmonic distortion and channel-to-channel isolation.

The digital interface provides a true asynchronous link between the A/D and a high speed microprocessor. Data transfer is controlled by generating an interrupt signal when data is available. Interrupts can be generated when the FIFO is full (32 words), half-full (16 words), or when a single word of data is ready (FIFO bypassed). The AD1334 can also generate an interrupt when the A/D conversion results are overrange.

The AD1334 provides a completely specified and tested system that bridges the interface and specification gap between A/D converters and high speed DSP.

NOTES

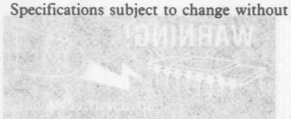
[1]Specifications are per channel in 4 Channel Simultaneous Mode (SAMPLE 0–3 connected together and $\overline{SIMULT}$ & CONTROL $\overline{ENB}$ = LOW), at f_S = 28 kHz, and with SAMPLE 0–3 having an 80% duty cycle unless noted.

[2]Group delay is the negative of the 1st derivative of phase with respect to frequency and is a measure of the analog time delay through the S/H.

[3]Aperture delay is the time delay from the SAMPLE input to S/H switch opening and is a measure of the digital time delay through the S/H.

[4]Effective aperture delay is the difference between analog and digital time delays described in (2) and (3).

[5]THD of harmonics 2–7 of the fundamental. SNR of fundamental less harmonics 2–7.



[6]Guaranteed over operating temperature and power supply voltage range.

[7]Isolation of any one channel from remaining three channels which have near maximum amplitude ac signals at their inputs.

[8]I_{OL} = 4 mA for AD1334BD, I_{OL} = 3.2 mA for AD1334TD; I_{OH} = −4 mA for AD1334BD, I_{OH} = −3.2 mA for AD1334TD.

[9]$\overline{RD}$, $\overline{CS}$, A0 = LOW; $\overline{WR}$, $\overline{RST}$ = HIGH.

Specifications subject to change without notice.

*Stresses above those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. This is a stress rating only and functional operation of the device at these or any other conditions above those indicated in the operational sections of this specification is not implied. Exposure to absolute maximum conditions for extended periods may affect device reliability.

CAUTION

ESD (electrostatic discharge) sensitive device. The digital control inputs are diode protected; however, permanent damage may occur on unconnected devices subject to high energy electrostatic fields. Unused devices must be stored in conductive foam or shunts. The protective foam should be discharged to the destination socket before devices are removed.

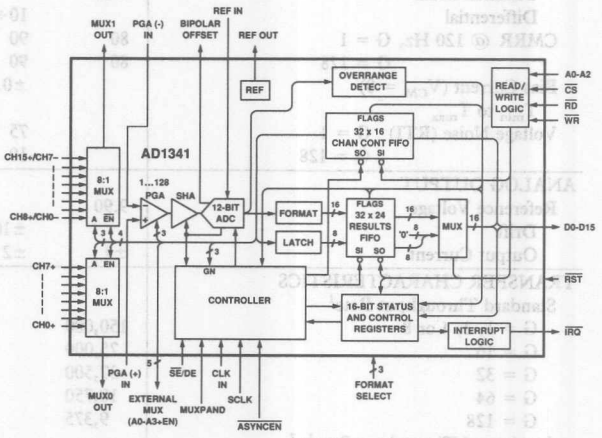
16-Channel Data Acquisition System

AD1341

FEATURES

150,000 Channels/Second Throughput Rate
Analog Inputs
- **16 Single-Ended (SE) or 8 Differential (DE); Expandable to 32 SE or 16 DE**
- **Over Voltage Protected**
- **Power Supply Loss Protected**

Programmable Gain Amplifier (PGA)
- **Binary Gains 1 to 128**
- **Independent Gain Selection per Channel**



12-Bit Sampling A/D Converter
Processor Interface
- **FIFOs for Channel Control and Conversion Results**
- **Fully Asynchronous 16-Bit Parallel Bus**
- **15 ns Data Access Time**
- **Selectable 16-Bit Data Format**
- **Programmable Interrupt Structure**

Ceramic Surface Mount Package

APPLICATIONS

DSP Data Acquisition
Missile Guidance
Vibration Analysis
Process Control

FUNCTIONAL BLOCK DIAGRAM

PRODUCT DESCRIPTION

The AD1341 is a complete 16-channel data acquisition system optimized for use in multichannel control and digital signal processing applications. The device consists of two 8-channel input multiplexers, a programmable gain amplifier (PGA), a 12-bit sampling A/D converter, two 32-word FIFOs, a controller, and registers for status and control. The device is packaged in a 100-lead ceramic quad flat package.

The input multiplexers can be configured for either 16 channels of single-ended input or 8 channels of differential input. The number of channels can be doubled with the addition of a single external 16-channel multiplexer. The inputs are protected against power loss for applications where the AD1341 is not powered from the same source as its inputs.

The programmable gain amplifier has differential inputs and 8 binary gain ranges from 1 to 128. Each channel can be programmed for a different gain. The controller timing allows the AD1341 to operate at the full 150,000 channels/second at gains from 1 to 8. Above 8, the throughput rate decreases proportionately to the increase in gain.

The 12-bit sampling A/D converter is specified and tested for both static and dynamic performance.

The AD1341 communicates asynchronously with the microprocessor over a 16-bit wide data path. Data can be formatted in either straight binary or twos complement with left, center or right justification. A 32-word FIFO is used to control channel selection and PGA gain. A second 32-word FIFO is used to store A/D conversion results.

PRODUCT HIGHLIGHTS

1. High throughput rate makes the AD1341 ideal for use in a wide range of applications in motion control, speech processing, PC data acquisition, medical instrumentation, and missile guidance.
2. Software development is simplified because timing for channel selection, PGA gain changing and settling, and A/D conversion is internal to the AD1341. Registers are available for enabling interrupt conditions and polling interrupt conditions or real-time status.
3. Software overhead is reduced by having FIFOs store channel information and conversion results.
4. Processor interface is simplified because the AD1341 operates fully asynchronously to the processor, has a maximum 15 ns data access time and is isolated by hybrid circuit construction.

NOTES

[1]All channel gains are fixed at the specified value.

[2]Accelerated performance is achieved through using a pipeline architecture and constant SHA acquisition times (see page 12 of this data sheet).

[3]f_{IN} = 4.6 kHz for G = 1, 2.3 kHz for G = 16 tests. SNR excludes harmonics 2–9. THD includes harmonics 2–9. Input amplitude is −0.3 dB relative to full-scale at each gain.

[4]Guaranteed over operating temperature range, tested at +25°C only.

Specifications subject to change without notice.

THEORY OF OPERATION

Functional Overview

The AD1341 is a complete data acquisition system designed with modern processor technology in mind. The heart of the AD1341 is a 12-bit Sampling Analog-to-Digital Converter with a maximum throughput of 150 kHz. The basic 10 V input range may be pin-strapped for either unipolar (0 to +10 V) or bipolar (−5 V to +5 V) operation. The ADC is preceded by a Programmable-Gain Instrumentation Amplifier possessing 8 binary-weighted gains between 1 and 128. Multiplexers provide 16 input channels which can be configured for either single-ended or 8-channel differential operation via a pin-strap option. All multiplexer inputs are fully protected against overvoltage and power-loss conditions. The multiplexer outputs and PGIA inputs are not internally connected to provide maximum flexibility and expansion capability. A +10 V reference output is also available.

The AD1341 offers a wide range of interface and control options. Programming and data readout are performed over a high speed asynchronous parallel 16-bit bus. Conversion results are stored in a 32-word FIFO which can be used to reduce I/O overhead. Six data formats are available. Sampling sequences of up to 32 channel/gain combinations are written to a command FIFO. A sampling sequence may be executed just once or may be continued indefinitely using the programmable Repeat mode. The AD1341 also includes expansion outputs which make possible a doubling of the number of input channels using a single external multiplexer. Expanded configurations retain all the operating features of a stand-alone AD1341. The interrupt structure is fully programmable. Status polling is fully supported. Finally, the AD1341 includes an independent programmable 16-bit countdown timer. Figure 13 shows a complete block diagram of the AD1341.

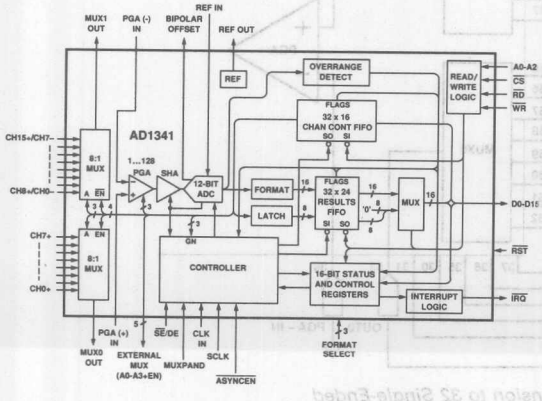

Figure 13. Functional Block Diagram

Input Configurations

The AD1341's ADC may be configured for either unipolar or bipolar inputs. Unipolar operation results when Ref Out (Pin 80) is connected to Ref In (Pin 79). BP Off (Pin 78) must be connected to Analog Signal Ground during unipolar operation. Bipolar operation requires the connection of Ref In, Ref Out, and BP Off. An external +10 V reference such as the AD2710 may be used if lower drift is required. A +10.24 V reference will provide a basic LSB size of 2 mV when the PGIA gain is set to 1.

The AD1341's multiplexer outputs and PGA inputs are not connected internally, but are instead brought out to package pins. Several pin-strapping options are possible to tailor the part to meet specific system requirements. The number of input channels may also be doubled with ease by using the AD1341's external multiplexer addressing capabilities.

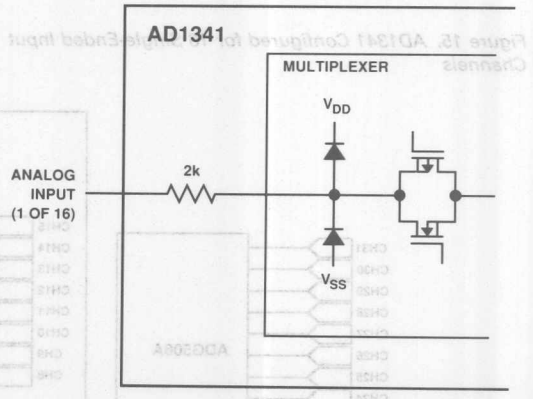

Figure 14. AD1341 Input Protection Circuitry

Single-ended or differential operation is selected using the $\overline{SE}$/DE input. When the MUXPAND input is grounded, the AD1341 can provide either 16 single-ended or 8 differential inputs. The number of inputs may be increased to 32 (single-ended) or 16 (differential) by pulling up the MUXPAND input and using an ADG506A multiplexer. Five expansion outputs enable and address the external multiplexer to give the expanded system the full functionality and programmability of a stand-alone AD1341. The four possible input schemes are shown in Figures 15 through 18, and the required pin-strapping is summarized in Table I.

A3 (ADG506A)			MUXA3	MUXA3

Table I. Connections for AD1341 Input Options

The AD1341's multiplexer inputs are protected against destructive latchup under power-loss and overvoltage conditions. Each input uses a 2 kΩ current-limiting resistor and two diodes to provide protection to at least 16 V beyond the analog supplies (Figure 14). The expanded input configurations in Figures 17 and 18 maybe similarly protected by adding 2 kΩ resistors in series with each external multiplexer input. Interactions between channels may occur under overload conditions. Unused AD1341 and ADG506A multiplexer inputs must be grounded.

Data Format Selection

Six data formats are available, offering a choice between natural binary and 2s complement coding with left, center, or right justification of the 12-bit result within the 16-bit field. The data format is determined by connections made to the three inputs FMT0, FMT1, and FMT2 (Pins 87, 86, and 85). These connections should be hardwired. Logical 0s are assigned to all unused places in the natural binary formats. The sign bit is extended as required and 0s are forced in empty least-significant places in the 2s complement formats. Tables II and III describe the data formats and their selection.

FMT2	FMT1	FMT0	Output Format
0	0	0	Natural Binary, Left Justified
0	0	1	Natural Binary, Right Justified
0	1	0	Natural Binary, Center Justified
0	1	1	Reserved
1	0	0	2s Complement, Left Justified
1	0	1	2s Complement, Right Justified
1	1	0	2s Complement, Center Justified
1	1	1	Reserved

range, and left-justified 2s complement data.

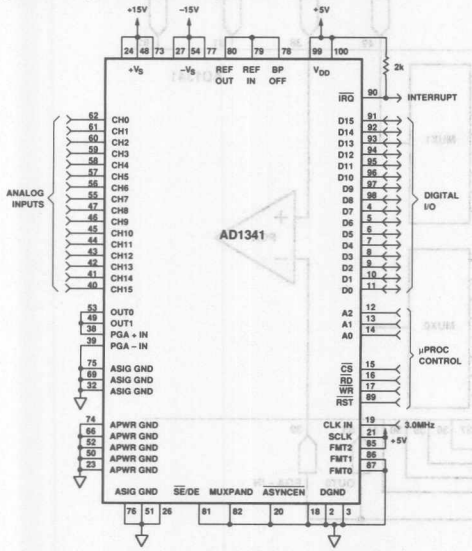

Figure 19. Typical Interface Circuit

Control Structure

The AD1341 is controlled through its digital interface. The device is completely disabled following power-up or a reset and must be programmed before conversions can be initiated.

Conversion sequences are stored in the Channel Control FIFO, from which they are subsequently executed. Each conversion instruction contains both a channel address and a channel gain. The Channel Control FIFO is 32 words deep.

Execution of programmed conversion sequences is enabled via the Mode Control Register. This register is also used to perform a programmed reset, to enable or disable interrupts, Repeat mode, and the timer, and to choose the system timing option. Selection from among a wide range of interrupt options is governed by the contents of the Interrupt Mask Register. Register contents may be read back for verification. A 32-word FIFO provides buffering for conversion results. The AD1341's register address space is defined in Table IV.

A2	A1	A0	Register Name/Function	Mnemonic	Type

Table IV. AD1341 Addresses

REGISTER DESCRIPTIONS

Channel Control Register (CCR)

The CCR is a 16-bit read/write register. Up to 32 CCR words may be written to the Channel Control queue for subsequent

CCR Description

Bit	B15	B14	B13	B12	B11	B10	B9	B8	B7	B6	B5	B4	B3	B2	B1	B0
Name	0	0	0	0	0	GN2	GN1	GN0	0	0	0	A4	A3	A2	A1	A0

Bits GN2 through GN0 control the PGIA gain. GN0 is the LSB. Gains are binary weighted, ranging from 1 to 128. A gain code of 000 corresponds to a gain of 1 and a gain code of 111 produces a gain of 128. Any channel may be programmed for any gain. A4 through A0 are channel address bits. A0 is the LSB. The range of available addresses depends upon the input configuration, which is determined by the wiring of the $\overline{SE}$/DE and MUXPAND inputs. Address ranges are outlined in Table V. Address bits invalid for the chosen input configuration must be written as 0s. Bits outside the gain and address fields are ignored during writes and set to 0 during reads.

Input Configuration	$\overline{SE}$/DE	MUXPAND	Valid Address Range
8-Channel Differential	1	0	0–7
16-Channel Single-Ended	0	0	0–15
16-Channel Differential	1	1	0–15
32-Channel Single-Ended	0	1	0–31

Table V. AD1341 Address Ranges

The CCR should be read only *after* reading a conversion result from the CRR (see below). Reading the CRR causes the related CCR data to be stored in a temporary register. The contents of this register are presented on the data bus during a subsequent CCR read. If the first CCR read is not performed before the second CRR read, the gain and channel information associated with the first CRR result will be lost.

Conversion Result Register (CRR)

The CRR is a 16-bit read-only FIFO register. The results of conversions are stored in the CRR up to 32 words deep. The results can be read out sequentially without reading the CCR in between, but the channel and gain information for the previous result will be discarded. In the descriptions below R0–R11 represent the conversion result and SE represents sign-extension bits. These will be the same as R11 for 2s complement numbers and are 0 for natural (unsigned) binary numbers.

CRR Description—Left Justified

Bit	B15	B14	B13	B12	B11	B10	B9	B8	B7	B6	B5	B4	B3	B2	B1	B0
Name	R11	R10	R9	R8	R7	R6	R5	R4	R3	R2	R1	R0	0	0	0	0

CRR Description—Center Justified

Bit	B15	B14	B13	B12	B11	B10	B9	B8	B7	B6	B5	B4	B3	B2	B1	B0
Name	SE	SE	R11	R10	R9	R8	R7	R6	R5	R4	R3	R2	R1	R0	0	0

CRR Description—Right Justified

Bit	B15	B14	B13	B12	B11	B10	B9	B8	B7	B6	B5	B4	B3	B2	B1	B0
Name	SE	SE	SE	SE	R11	R10	R9	R8	R7	R6	R5	R4	R3	R2	R1	R0

Overrange and underrange results in natural binary format are coded as twelve 1s and twelve 0s, respectively, and are positioned within the 12-bit field as determined by the selected

These results will also be properly justified and sign-extended.

Mode Control Register (MCR)

The MCR is a 16-bit read/write register. It contains six active bits. The reset (default) state for all bits is 0.

MCR Description

Bit	B15	B14	B13	B12	B11	B10	B9	B8	B7	B6	B5	B4	B3	B2	B1	B0
Name	INT	0	RST	0	CVN	0	REP	0	TIM	0	ACC	0	0	0	0	0

INT enables or disables the interrupt mask register (IMR). Interrupt generation under IMR control is enabled when INT is set to 1. New interrupts are disabled when INT is set to 0, but any interrupts pending when INT was set to 0 are not affected.

RST provides a programmed AD1341 reset. Writing a 1 to RST causes all registers and FIFOs to be reset to their default states. RST remains set until the reset sequence is complete, at which time it is cleared. A reset sequence requires one complete clock cycle and may take up to 667 ns (assuming a 3 MHz clock) depending upon the timing of the MCR write relative to the system clock.

CVN enables or disables conversions under host control. Setting CVN begins the execution of the conversion sequence stored in the CCR. Clearing CVN prevents the initiation of further conversions; any in-process conversion(s) will be completed and the conversion results written to the CRR. An in-process conversion is one for which the gain and channel instruction has been clocked out of the CCR. CVN may be set again anytime after it has been cleared; any conversions still in the CCR will resume in an orderly fashion.

REP enables the Repeat mode when set to 1. This bit may be set at any time. Setting REP disables any further writing to the CCR. Once REP has been set, the data written into the CCR queue since the last read will be repeated in a circular fashion. If Repeat mode is enabled after conversions have begun only the unexecuted conversions in the CCR queue will be repeated. Repeat mode functions with any number of instructions in the CCR queue. Clearing REP clears the CCR queue and the controller in preparation for receiving new data and starting new conversions.

TIM is used to disable or enable the 16-bit internal timer. The timer is disabled when TIM is set to 0, and enabled when TIM is set to 1. When enabled the counter counts down from the count stored in the TMR and generates an interrupt (if the timer interrupt is enabled). The preset count is then reloaded from the TMR and another countdown cycle begins on the next clock edge. Clearing TIM will halt the timer and clear its count. The contents of the TMR are not affected by clearing TIM. If the timer is enabled after having been disabled, it will begin its countdown from the previously programmed count. A Terminal Count signal is available on Pin 22.

ACC permits selection between standard and accelerated system timing (see *Conversion Timing*). Standard timing is selected when ACC is set to 0, and accelerated (optimized) timing is selected when ACC is set to 1.

Timer Register (TMR)

The TMR is a read/write register used to load and query the general purpose timer. Writing to the TMR will program a time

delay time = programmed count × basic delay unit.

The basic delay unit is one clock period, or 333.3 ns with a 3.00 MHz clock, and the maximum delay is 65535 basic delay units. T15 is the MSB. The reset (default) state for the TMR is 0. There may be an uncertainty of 1 clock period on the first countdown interval after the timer is enabled. All subsequent timer intervals will be identical and equal to the programmed delay provided timer operation is not interrupted.

TMR Description

Bit	B15	B14	B13	B12	B11	B10	B9	B8	B7	B6	B5	B4	B3	B2	B1	B0
Name	T15	T14	T13	T12	T11	T10	T9	T8	T7	T6	T5	T4	T3	T2	T1	T0

Reading the TMR will give the current programmed value. Reads are supported only when the timer is disabled. It is not possible to read the timer status during timer operation.

Interrupt Mask Register (IMR)

The IMR is a 16-bit read/write register. Setting bits in the IMR determines the conditions used to generate an interrupt to the host processor. The desired interrupt condition(s) is set by writing a 1 to the appropriate bit(s); all other IMR bits must be written as 0s. The reset (default) state for the IMR is all bits 0.

IMR Description

Bit	B15	B14	B13	B12	B11	B10	B9	B8	B7	B6	B5	B4	B3	B2	B1	B0
Name	0	CVD	CVP	TME	0	ORG	0	CCF	CCH	CCE	0	0	0	CRF	CRH	CRE

Set IMR bits have the following effects:

CVD will cause an interrupt to be asserted every time a conversion result is shifted into the CRR.

CVP will cause an interrupt to be asserted when the conversion result obtained by executing the last command in the CCR is shifted into the CRR. The condition for a CVP interrupt is sensed at the scheduled start of the "last" conversion (see *Conversion Timing*). Writing another command to the CCR prior to the scheduled start of the "last" conversion will block the CVP interrupt.

TME will cause an interrupt to be asserted when the timer count reaches zero.

ORG will cause an interrupt to be asserted whenever overrange data are shifted into the CRR.

CCF will cause an interrupt to be asserted when the CCR queue is full. The CCR depth is 32 words.

CCH will cause an interrupt to be asserted when the CCR queue is at least half full (contains at least 16 words).

CCE will cause an interrupt to be asserted when the last channel/gain command is shifted out of the CCR and the conversion programmed therein begins. It is this conversion which leads to a CVP interrupt if no further commands are written to the CCR.

CRF will cause an interrupt to be asserted when the CRR is full. The CRR depth is 32 words.

CRH will cause an interrupt to be asserted when the CRR is at least half full.

CRE will cause an interrupt to be asserted when the CRR is empty.

Status Register (STS)

The Status Register is a 16-bit read only register which provides a continuous summary of the AD1341's internal state. The default condition for all STS bits is transparent. When an interrupt condition is enabled, the STS will latch the corresponding bit upon the assertion of the enabled interrupt; all other bits remain transparent. *The interrupt will remain asserted until the processor reads the STS contents; any latched STS bits will be reset to transparent mode once the read operation is completed.* Any pending interrupt conditions will continue the interrupt request once the STS register is read. The EVT bit is set whenever any of the unmasked interrupt conditions has generated an interrupt request.

STS Description

Bit	B15	B14	B13	B12	B11	B10	B9	B8	B7	B6	B5	B4	B3	B2	B1	B0
Name	EVT	CVD	CVP	TME	0	ORG	0	CCF	CCH	CCE	0	0	0	CRF	CRH	CRE

STS bits correspond to IMR bits with the exception of EVT. STS bits have the following meanings:

EVT is set whenever an enabled interrupt event has occurred. This bit cannot be cleared directly by the user and remains set until the interrupt has been serviced.

CVD is set whenever a conversion is completed.

CVP is set whenever the conversion pipeline (CCR queue) is empty.

TME is set when the timer expires.

ORG is set when overrange or underrange data are shifted into the CCR.

CCF is set when the CCR queue has been filled.

CCH is set when the CCR queue is at least half full.

CCE is set when the CCR queue has been emptied.

CRF is set when the CRR FIFO is full.

CRH is set when the CRR FIFO is at least half full.

CRE is set when the CRR FIFO is empty.

Some of the remaining STS bit positions are used for diagnostic purposes. These bits (B11, B9, B5, B4, and B3) should be masked during normal operation.

FIFO Boundary Conditions

Overflow conditions occur whenever more than 32 words are written to either the CCR or the CRR. In both cases, data beyond the 32nd word are lost. The first 32 data words are not affected.

An underflow condition occurs when more than 32 words are read out of the CRR. The last valid word remains in the CRR and will be placed on the bus repeatedly in response to additional read commands. The CCR queue cannot underflow. Conversions cease after the last command in the CCR has been read and executed when Repeat mode is disabled.

Conversion Timing

The AD1341 normally overlaps some of its signal processing functions to maximize throughput. Such pipelining provides maximum throughput when multiple conversion instructions are buffered in the CCR and executed sequentially using the internal controller. Externally triggered conversions are also possible, either with or without pipelining. Finally, the internal timer may be used in conjunction with external triggering to further customize the sampling rate.

Pipelined Conversions

Normal pipelined operation is enabled by grounding the $\overline{\text{ASYNCEN}}$ input (Pin 20) and tying the SCLK input to V_{DD}. In this mode the AD1341's timing is governed by its internal controller. Channel and gain instructions for conversion N+1 are read from the CCR and executed at the start of A/D conversion N. This permits the PGIA's settling to occur during the A/D conversion. The AD1341's throughput depends on the number of channels and the gain mix because of the variation in PGIA settling time with gain. The internal sequencer always provides the proper settling time for the active channel regardless of the number of channels used or the gains selected.

There are two sequencer modes, Standard and Accelerated, selected using the ACC bit (Bit 5) in the MCR. Standard timing mode increases both the SHA acquisition time and the PGIA settling time for higher gains. Accelerated mode maintains constant SHA acquisition time independent of gain and provides maximum system throughput. Table VI details throughput performance for the two timing modes. The listed throughputs assume all channels operate at the same gain.

	Standard Mode		Accelerated Mode	
Gain	Clocks per Pipelined Conversion	Throughput, Pipelined (kHz)	Clocks per Pipelined Conversion	Throughput, Pipelined (kHz)
1–8	20	150.00	20	150.00
16	40	75.00	30	100.00
32	80	37.50	52	57.69
64	160	18.75	102	29.41
128	320	9.38	202	14.85

Table VI. AD1341 Timing and Throughput (3 MHz Clock)

When Repeat mode is enabled, the instructions in the CCR are read and executed indefinitely in a circular fashion. The per-channel sampling rate in Repeat mode for arbitrary numbers of channels and various gains can be determined with a simple calculation. This calculation uses the "Clocks per Pipelined Conversion" data from Table VI and the programmed channel and gain mix. Each channel is sampled at the calculated rate, while the exact sample time will be determined by the specific channel and gain order. The example below an assumes input expansion as shown in Figure 17.

11 channels at gains between 1 and 8	$11 \times 20 = 220$ clock periods
8 channels at gain of 16	$8 \times 30 = 240$ clock periods
5 channels at gain of 32	$5 \times 52 = 260$ clock periods
2 channels at gain of 64	$2 \times 102 = 204$ clock periods
4 channels at gain of 128	$4 \times 202 = 808$ clock periods
30 channels	1732 clock periods

$$\textit{System sample rate} = \frac{1}{1732 \times 333.33\ ns} = 1.73210\ kHz$$

Calculation of System Sample Rate (Accelerated Timing Mode, 3 MHz Clock)

It is also possible to measure the system sample rate by counting the number of clock periods between successive rising edges of the CC output. CC goes high at the start of the last conversion in a sequence and remains high until that conversion is completed. CC does not toggle when a single conversion is repeated. The duty cycle of CC depends on the number of channels in a sequence and their gains. Transitions of CC occur on rising clock edges.

Externally Triggered Conversions

Conversions may be triggered directly by the host system when $\overline{\text{ASYNCEN}}$ is tied to V_{DD}. *Externally triggered conversions may only be used with Repeat mode enabled.* Channel and gain information must first be written to the CCR. After all CCR writes are completed, REP (MCR Bit 9) should be set by the host processor. This clocks out the first CCR instruction, setting the multiplexer address and PGIA gain. A subsequent rising edge on the SCLK input places the SHA into Hold mode and triggers the A/D conversion, which is clocked to its completion using the 3 MHz clock. The first rising clock edge following the rising edge of SCLK also clocks the next channel/gain word from the CCR, permitting the pipelining of externally triggered conversions. The typical setup time for SCLK high relative to the rising edge of the clock is 10 ns.

The AD1341's acquisition timing controller is inoperative when $\overline{\text{ASYNCEN}}$ is tied high, so the host system must provide sufficient time to acquire each input before pulsing the SCLK line. Failure to do so will produce an incorrect conversion result. The minimum time required for a given gain may be found using the "Clocks per Pipelined Conversion" columns of Table VI. Externally triggered conversions have an inherent timing uncertainty of 1 clock period (333.3 ns with a 3 MHz clock) when SCLK is not synchronized with the external clock.

SCLK functions much like the Start-Convert input of a standard ADC. Unlike a conventional ADC, however, the AD1341 lacks a $\overline{\text{BUSY}}$ or STATUS output. The IMR may be programmed to cause an interrupt at the completion of each conversion, which will make the $\overline{\text{IRQ}}$ output functionally similar to a traditional $\overline{\text{BUSY}}$ or STATUS output. All AD1341 interrupt conditions function normally with externally-triggered conversions.

Timer-Controlled Conversions

The AD1341's programmable timer may be used to control externally triggered conversions, making possible extremely low sample rates with minimal host overhead. *Timer-controlled conversions may only be used with Repeat mode enabled.* TC (Pin 22) should be connected to SCLK (Pin 21), and the timer must be programmed to generate a delay at least equal to the largest required number of "Clocks per Pipelined Conversion" from Table VI.

MCR Bits 7 and 9 should be set after the CCR and TMR have been programmed. This will clock out the first CCR instruction and start the timer. The first input channel is sampled and the A/D conversion begins with first rising edge of the TC output, which indicates the end of the timer interval. This edge also clocks the next instruction from the CCR, reloads the timer delay stored in the TMR, and restarts the timer. A conversion is performed every time the timer expires until the AD1341 is reprogrammed or reset.

Single Conversions

Repeat must be disabled to perform a single conversion. The desired channel and gain must first be written to the CCR. Setting CVN (MCR Bit 11) will begin the conversion under internal timing control when $\overline{\text{ASYNCEN}}$ is low. The times required to perform the acquisition and conversion of a single sample are listed in Table VII; these times are measured from the first rising clock edge after CVN has been set. The typical setup time for CVN (trailing edge of $\overline{\text{WR}}$ to rising edge of CLK) is 10 ns.

Because acquisition and conversion begin on a clock edge rather than precisely when CVN is set, there may be an uncertainty in the instant at which the input is sampled. The variation will be up to one clock period in systems in which bus operation is not synchronous with the AD1341's 3 MHz clock, and one clock period (333 ns) should be added to the contents of Table VII to account for this. These variations can be eliminated when the host system's bus is synchronized with the 3 MHz clock provided CVN's setup time is met.

Gain	Standard Mode Conversion Time, µs	Accelerated Mode Conversion Time, µs
1–8	11.00	11.00
16	17.67	15.00
32	31.00	23.33
64	57.67	40.00
128	111.00	73.33

Table VII. AD1341 Conversion Times (3 MHz Clock, $\overline{\text{ASYNCEN}}$ Low)

With $\overline{\text{ASYNCEN}}$ high, single conversions may be triggered externally. The channel and gain instruction is clocked from the CCR when REP is set, and signal acquisition begins at that time. The rising edge of SCLK places the SHA into Hold mode, and the A/D conversion begins on the first rising clock edge following the SCLK transition. Table VIII lists the minimum permissible acquisition times between setting CVN and the rising edge of SCLK, along with the time required for the actual A/D conversion. The total conversion time is the sum of Table VIII's acquisition time and A/D time.

	Standard Mode		Accelerated Mode	
Gain	Acquisition Time, µs	A/D Time, µs	Acquisition Time, µs	A/D Time, µs
1–8	6.67	4.33	6.67	4.33
16	13.33	4.33	10.67	4.33
32	26.67	4.33	19.00	4.33
64	53.33	4.33	35.67	4.33
128	106.67	4.33	69.00	4.33

Table VIII. AD1341 Timing and Throughput (3 MHz Clock)

There is an uncertainty of one clock period in *both* the acquisition and A/D times listed in Table VIII when system operation is asynchronous. The first of these uncertainties arises from the variable relationship between the trailing edge of $\overline{\text{WR}}$ with respect to the rising edge of CLK, while the second results from the timing uncertainty between the rising edges of CLK and SCLK.

APPLICATIONS

Analog Interface

Each of the AD1341's 16 multiplexer inputs is protected against overvoltage and power-loss conditions by a series resistor and two diodes (Figure 14). Each input's time constant is typically 50 ns when the AD1341 is strapped for differential inputs and 100 ns in the single-ended configuration. The settling delays caused by these time constants have been accounted for in the AD1341's internal timing generator. Additional external series resistance will increase these time constants and could prevent the inputs from settling within the time allotted. For this reason the AD1341's inputs are best driven by low-impedance sources such as op amp outputs.

The AD1341's multiplexer outputs and PGIA inputs are brought out of the package to permit easy system expansion. Excessive capacitance at these pins should be avoided as it will also interfere with settling. All connections should be kept as short and direct as possible to minimize capacitance and noise coupling. (The AD1341's timing generator allows sufficient input settling time with the capacitance added by the expansion multiplexer as shown in Figures 17 and 18.)

A small amount of charge is dumped through each input whenever it is selected or deselected. The magnitude of this charge is typically 4 pC. Each signal source should have a low output impedance at high frequencies in order to absorb this transient. Micropower op amps may have difficulty with this type of transient because of their generally higher output impedances and lower gain-bandwidth products. The AD711, AD712, and AD713 are good choices for driving the AD1341's inputs.

Each multiplexer input requires a return path for off-state leakage currents. The driving source normally supplies this path. Unused inputs must not be left floating and should be connected to the analog ground plane.

Power Supplies and Grounds

Proper grounding and power supply bypassing techniques are necessary to obtain the AD1341's specified performance. The AD1341 has separate connections for analog signal ground, analog power ground, and digital ground. All Analog Signal and Power Ground pins must be connected to a common ground plane beneath the AD1341. This will provide the low impedance path required to minimize coupling between dynamic supply currents and low level signals being processed by the AD1341.

The AD1341's metal lid is internally connected to Analog Power Ground to provide maximum shielding against electrical interference. The lid faces the circuit board when the AD1341 is soldered in place. The board surface directly beneath the AD1341 should not contain signal or power traces to eliminate the possibility of short circuits. Using this area as a ground plane will result in the lowest possible ground impedance and will preserve signal fidelity.

The Digital Ground pins should also be connected to this ground plane if at all possible. This will provide the greatest immunity to digital switching noise. If this causes ground loops or other system-level problems then a separate ground plane or other low impedance return path must be provided. In this case the analog and digital grounds should be connected together at the AD1341 using back-to-back Schottky diodes and a good high frequency bypass capacitor. Ceramic capacitors in the range 0.01–0.1 μF are recommended. These components will prevent destructive dc potential differences between grounds and will also provide a low impedance path for transient currents.

Each power supply should be capacitively bypassed to the ground plane(s) with the capacitors located as closely as possible to the device in order to provide a low source impedance for dynamic signal and supply currents. Both ceramic and solid tantalum capacitors should be used for each supply. Appropriate values are 0.01–0.1 μF for ceramic capacitors and 1–10 μF for tantalum capacitors. Aluminum electrolytic capacitors have much higher equivalent series resistance than comparable-value tantalum devices and are not recommended.

Digital Interface

The AD1341's fast parallel bus simplifies the system designer's task by permitting zero-wait-state operation in most applications. In many cases the interface between the AD1341 and a microprocessor requires nothing more than an address decoding function. Figures 20 through 23 illustrate the AD1341's interface with several popular single-chip digital signal processors.

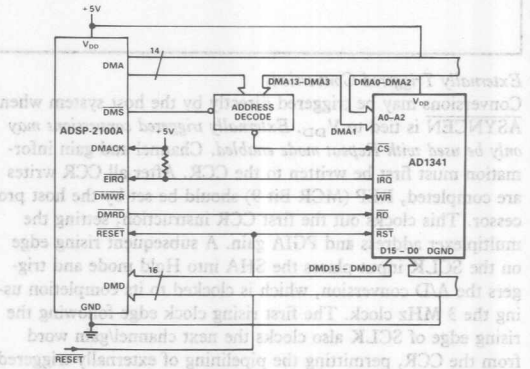

Figure 20. ADSP-2100A to AD1341 Interface

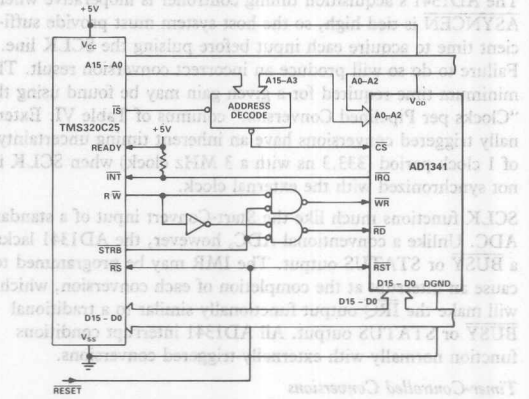

Figure 21. TMS320C25 to AD1341 Interface

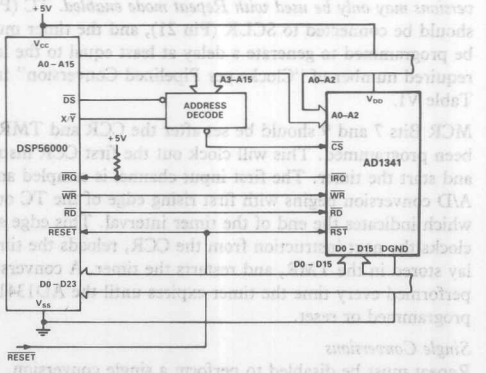

Figure 22. DSP56000 to AD1341 Interface

The AD1341's digital interface provides TTL- and CMOS-compatible levels with 10K ECL speed, exhibiting typical edge rates of 1.4 ns with 15 pF loading. Proper layout and impedance

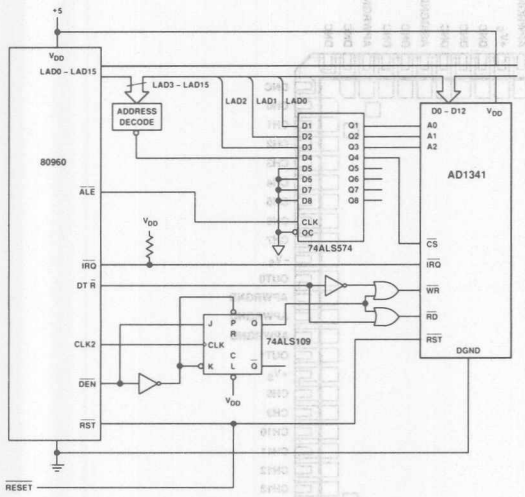

Figure 23. 80960 to AD1341 Interface

matching techniques are essential to prevent problems caused by crosstalk, reflections, and ground bounce.

Crosstalk

The fast edge rates and large voltage swings in CMOS systems will cause capacitive and inductive coupling (crosstalk) between adjacent PCB circuit traces. This will compromise signal integrity and reduce noise margins. The effect is most severe on "clocked" control lines ($\overline{RD}$, $\overline{WR}$, and $\overline{CS}$) which are close to data lines. The coupled noise may be large enough to initiate spurious I/O operations.

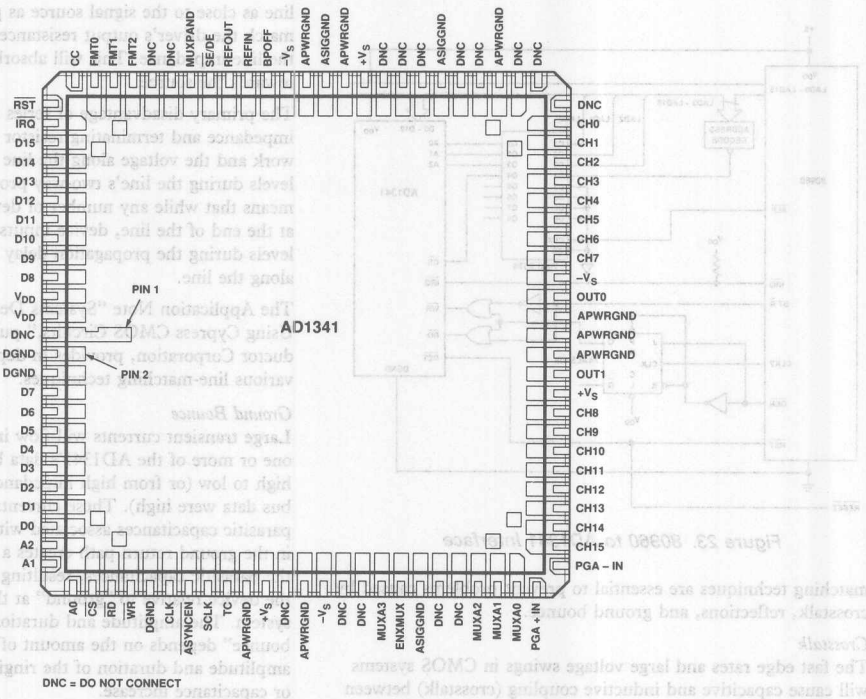
Crosstalk can be reduced by eliminating long parallel PCB circuit traces and by routing data lines away from clocked control lines. Grounded circuit traces may also be used to provide shielding between data and control lines, but this is less effective than physical separation.

Reflections

The gross impedance mismatches between high impedance CMOS inputs, low impedance CMOS outputs, and typical PCB circuit trace impedances can lead to voltage reflections and ringing. Reflections from impedance discontinuities become important whenever the line's round-trip delay exceeds the driving signal's rise or fall time. The critical line length, beyond which reflections begin to play a role, is only 13 cm for the AD1341, assuming an edge rate of 1.4 V/ns and a line delay of 0.055 ns/cm. The critical line length can be increased by running the signal lines over a ground plane because the added capacitance will reduce the edge rate (at the expense of increasing ground bounce).

A much better solution is to provide proper terminations for all signal lines. The AD1341's CMOS outputs do not have sufficient current drive capability to permit terminating PCB lines in their characteristic impedance. Series damping is a satisfactory alternative means to reduce reflections and ringing. A small resistor (typically 10 Ω to 75 Ω) is placed in series with the signal line as close to the signal source as possible. The goal is to match the driver's output resistance plus the series resistance to the line impedance. This will absorb any wave reflected back towards the source.

The primary disadvantage of series termination is that the line impedance and terminating resistor form a voltage divider network and the voltage along the line may lie between valid logic levels during the line's two-way propagation delay time. This means that while any number of device inputs may be connected at the end of the line, device inputs which require valid logic levels during the propagation delay time cannot be distributed along the line.



The Application Note "Systems Design Considerations When Using Cypress CMOS Circuits," published by Cypress Semiconductor Corporation, provides in-depth analysis and discussion of various line-matching techniques.

Ground Bounce

Large transient currents will flow into digital ground whenever one or more of the AD1341's data bus outputs switches from high to low (or from high impedance to low when the previous bus data were high). These currents result from the discharge of parasitic capacitances associated with the data bus. Inductance in the ground return path creates a resonant L-C circuit with the parasitic capacitances, resulting in ringing in "ground" at the device relative to "ground" at the supply or elsewhere in the system. The amplitude and duration of this ringing, or "ground bounce" depends on the amount of parasitic reactance. Both the amplitude and duration of the ringing increase as the inductance or capacitance increase.

The effect of ground bounce is to degrade the logic-low noise margin. This can result in system data errors. In particularly severe cases it can initiate spurious I/O operations in the AD1341 and cause the loss of data. The best defenses against ground bounce are to minimize the capacitive loading of the data bus and to use a ground plane to provide a low impedance return path for the inevitable transient currents. When large bus capacitance is unavoidable, it may prove beneficial to use BiCMOS bus transceivers between the AD1341 and the system data bus. This will increase both read and write cycle times, but the controlled edge speeds will reduce the peak currents, decreasing the possibility of erroneous data or I/O operations. The transceivers should be located close to the AD1341 to minimize the capacitance seen by the AD1341's data outputs.

16-Channel, 12-Bit Data Acquisition System

AD1362

FEATURES

- **Pin and Functional Replacement for AD362:**
  - **Lower Power Dissipation**
  - **Lower Noise**
  - **Internal Hold Capacitor**
- **16 Single-Ended or 8 Differential Channels with Switchable Mode Control**
- **True 12-Bit Precision: Nonlinearity ≤0.005%**
- **High Speed: 10μs Acquisition Time to 0.01%**
- **Complete and Calibrated: No Additional Parts Required**
- **Versatile: Simple Interface to Popular Analog-to-Digital Converters**
- **High Differential Input Impedance ($10^{10}\Omega$) and Common Mode Rejection (80dB)**
- **Fully Protected Multiplexer Inputs**

FUNCTIONAL BLOCK DIAGRAM

PRODUCT DESCRIPTION

The AD1362 is a complete, precision16-channel data acquisition system. The device contains two 8-channel multiplexers, a differential amplifier, a sample-and-hold with high-speed output amplifier, a channel address latch and control logic. The multiplexers may be connected to the differential amplifier in either an 8-channel differential or 16-channel single-ended configuration. A unique feature of the AD1362 is an internal user-controllable analog switch that connects the multiplexers in either a single-ended or differential mode. This allows a single device to perform in either mode without hard-wire programming and permits a mixture of single-ended and differential sources to be interfaced by dynamically switching the input mode control.

The sample-and-hold mode control is designed to connect directly to the "Status" output of an analog-to-digital converter so that a convert command to the ADC will automatically put the sample-and-hold into the "Hold" mode. An internal precision hold capacitor is included with each AD1362. The AD1362 output amplifier is capable of driving the unbuffered analog input of most high speed, 12-bit successive-approximation ADCs. The interface is thereby reduced to two simple connections with no additional components required.

The AD1362KD is specified for operation over a 0 to +70°C temperature range while the AD1362SD operates to specification from −55°C to +125°C. Processing to MIL-STD-883, Class B is available for the AD1362SD. Both grades are packaged in a hermetic 32-pin ceramic dual-in-line package.

PRODUCT HIGHLIGHTS

1. The AD1362, when used with a precision analog to digital converter, forms a complete, accurate, high-speed data acquisition system.
2. The 16-input channels may be configured in single-ended, differential or a mixture of both modes. Mode switching is provided by a user controllable internal analog switch.
3. Multiplexers, differential amplifier, sample-and-hold and high-speed output buffer provide complete analog interfacing capabilities.
4. Internal channel address latches are provided to facilitate interfacing the AD1362 to data, address or control buses.
5. The AD1362 is specified over the entire military temperature range, −55°C to +125°C. Processing to MIL-STD-883, Class B is available.

channel address latches and control logic as shown in the block diagram. The multiplexers can be connected to the differential amplifier in either an 8-channel differential or 16-channel single-ended configuration. A unique feature of the AD1362 is an internal analog switch controlled by a digital input that performs switching between single-ended and differential modes. This feature allows a single AD1362 to perform in either mode without external hard-wire interconnections. Of more significance is

AD1362 Block Diagram

Multiplexer channel address inputs are interfaced through a level-triggered ("transparent") input register. With a Logic "1" at the Latch Select input, the address signals feed through the register to directly select the appropriate input channel. This address information can be held in the register by placing a Logic "0" on the Latch Select input. Internal logic monitors the status of the Single-Ended/Differential Mode input and addresses the multiplexers accordingly.

A differential amplifier buffers the multiplexer outputs while providing high input impedance in both differential and single-ended modes.

The sample-and-hold is a high speed device that can also function as a gated operational amplifier. Its uncommitted differential inputs allow it to serve a second role as the output subtractor in the differential amplifier. A Logic "1" on the Sample-and-Hold Command input will cause the sample-and-hold to "freeze" the analog signal while the ADC performs the conversion. Normally the Sample-and-Hold Command is connected to the ADC Status output which is at Logic "1" during conversion and Logic "0" between conversions. For slowly changing inputs, throughput speed may be increased by grounding the Sample-and-Hold Command input instead of connecting it to the ADC status.

The output buffer is a high speed amplifier whose output impedance remains low and constant at high frequencies. Therefore, the AD1362 may drive a fast, unbuffered, precision ADC without loss of accuracy.

THEORY OF OPERATION

Concept

The AD1362 is intended to be used in conjunction with a high speed, precision analog-to-digital converter to form a complete data acquisition system (DAS). Figure 1 shows a general AD1362 with ADC DAS application.

By dividing the data acquisition task into two sections, several important advantages are realized. Performance of each design is optimized for its specific function. Production yields are increased thus decreasing costs. Furthermore, the standard configuration packages plug into standard sockets and are easier to handle than larger packages with higher pin counts.

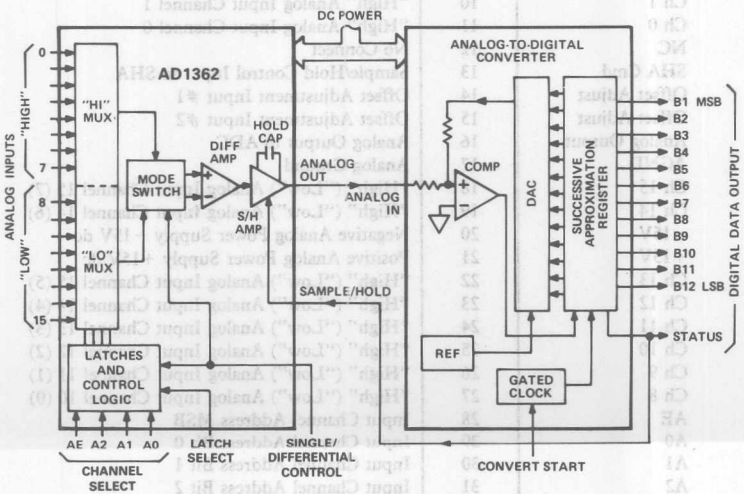

Figure 1. AD1362 with ADC as a Complete Data Acquisition System

System Timing

Figure 2 is a timing diagram for the AD1362 connected as shown in Figure 1 and operating at maximum conversion rate. The ADC is assumed to be a conventional 12-bit type such as the AD573 or AD ADC80.

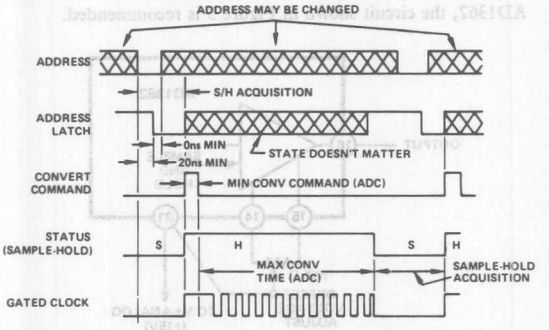

Figure 2. DAS Timing Diagram

The normal sequence of events is as follows:

1. The appropriate Channel Select Address is latched into the address register. Time is allowed for the multiplexers to settle.
2. A Convert Start command is issued to the ADC which, in response, indicates that it is "busy" by placing a Logic "1" on its Status Line.
3. The ADC Status controls the sample-and-hold. When the ADC is "busy," the sample-and-hold is in the Hold mode.
4. The ADC goes into its conversion routine. Since the sample-and-hold is holding the proper analog value, the address may be updated during conversion. Thus multiplexer settling time can coincide with conversion and need not affect throughput rate.
5. The ADC indicates completion of its conversion by returning Status to Logic "0." The sample-and-hold returns to the Sample mode.
6. If the input signal has changed full scale (different channels may have widely-varying data), the sample-and-hold will typically require 10 microseconds to "acquire" the next input to sufficient accuracy for 12-bit conversion.

After allowing a suitable interval for the sample-and-hold to stabilize at its new value, another Convert Start command may be issued to the ADC.

NOTE

Valid Output Data

Not all ADCs have all data bits available when Status indicates that the conversion is complete. Some successive approximation ADCs must have a Status delay built in or the final data bit will lag Status. This will result in two problems:

1. The sample-and-hold will return to Sample, disturbing the analog input to the ADC as it is attempting to convert the least significant bit. This may result in an error.
2. If the falling edge of Status is being used to load the data into a register, the least significant bit will not be valid when loaded.

An external delay or use of an ADC with a valid Status output is necessary to prevent this problem.

Single-Ended/Differential Mode Control

The AD1362 features an internal analog switch that configures the Analog Input Section in either a 16-channel single-ended or 8-channel differential mode. This switch is controlled by a TTL logic input applied to Pin 1:

"0": Single-Ended (16 channels)
"1": Differential (8 channels)

When in the differential mode, a differential source may be applied between corresponding "High" and "Low" analog input channels.

It is possible to mix SE and DIFF inputs by using the mode control to command the appropriate mode. In this case, four microseconds must be allowed for the output to settle to within ±0.01% of its final value, but if the mode is switched concurrent with changing the channel address, no significant additional delay is introduced. The effect of this delay may be eliminated by changing modes while a conversion is in progress (with the sample-and-hold in the "Hold" mode). When SE and DIFF signals are being processed concurrently, the DIFF signals must be applied between corresponding "High" and "Low" analog input channels. Another application of this feature is the capability of measuring 16 sources individually and/or measuring differences between pairs of those sources.

Input Channel Addressing

Table I is the truth table for input channel addressing in both the single-ended and differential modes. The 16 single-ended channels may be addressed by applying the corresponding digital number to the four Channel Select address bits, AE, A0, A1, A2 (Pins 28–31). In the differential mode, the eight channels are addressed by applying the appropriate digital code to A0, A1, and A2; AE must be enabled with a Logic "1." Internal logic monitors the status of the SE/DIFF Mode input and addresses the multiplexers singularly or in pairs as required.

When the channel address is changed, six microseconds must be allowed for the AD1362 to settle to within ±0.01% of its final output (including settling times of all elements in the signal path). The effect of this delay may be eliminated by performing the address change while a conversion is in progress (with the sample-and-hold in the "Hold" mode).

ADDRESS				ON CHANNEL		
					Differential	
AE	A2	A1	A0	Single Ended	"Hi"	"Lo"
0	0	0	0	0	None

1	1	0	1	13	5	5
1	1	1	0	14	6	6
1	1	1	1	15	7	7

Table I. Input Channel Addressing Truth Table

Input Channel Address Latch

The AD1362 is equipped with a latch for the input Channel Select address bits. If the Latch Select pin is at Logic "1," input channel select address information is passed through to the multiplexers. A Logic "0" "freezes" the input channel address present at the inputs at the "1"-to-"0" transition (level-triggered).

This feature is useful when input channel address information is provided from an address, data or control bus that may be required to service many devices. The ability to latch an address is helpful whenever the user has no control of when address information may change.

Sample-and-Hold Mode Control

The Sample-and-Hold Mode Control input is normally connected to the Status output from an analog to digital converter. When a conversion is initiated by applying a Convert Start command to the ADC, Status goes to Logic "1" putting the sample-and-hold into the "Hold" mode. This "freezes" the information to be digitized for the period of conversion. When the conversion is complete, Status returns to Logic "0" and the sample-and-hold returns to the "Sample" mode. Eighteen microseconds must be allowed for the sample-and-hold to acquire ("catch up" to) the analog input to within ±0.01% of the final value before a new Convert Start command is issued.

The purpose of a sample-and-hold is to "stop" fast changing input signals long enough to be converted. In this applicatain, it also allows the user to change channels and/or SE/DIFF mode while a conversion is in progress thus eliminating the effects of multiplexer, analog switch and differential amplifier settling times. If maximum throughput rate is required for slowly changing signals, the Sample-and-Hold Mode Control may be wired to ground (Logic "0") rather than to ADC Status thus leaving the sample-and-hold in a continuous Sample mode.

Analog Input Section Offset Adjust Circuit

Although the offset voltage of the AD1362 may be adjusted, that adjustment is normally performed at the ADC. In some special applications, however, it may be helpful to adjust the offset of the Data Acquisition System. An example of such a case would be if the input signals were small (<10mV) relative to AD1362 offset and gain errors. To adjust the offset of the AD1362, the circuit shown in Figure 3 is recommended.

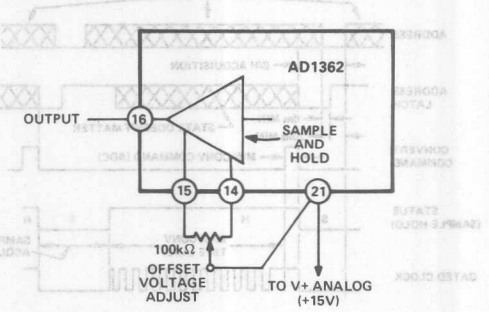

Figure 3. AD1362 Offset Voltage Adjustment

Under normal conditions, all calibration is performed at the ADC Section.

Other Considerations

Grounding: Analog and digital signal grounds should be kept separate where possible to prevent digital signals from flowing in the analog ground circuit and inducing spurious analog signal noise. Analog Ground and Digital Ground are not connected internally; these pins must be connected externally for the system to operate properly. Preferably, this connection is made at only one point, as close to the AD1362 as possible. The case is connected internally to Digital Ground to provide good electrostatic shielding. If the grounds are not tied common on the same card with the AD1362, the digital and analog grounds should be connected locally with back-to-back general-purpose diodes as shown in Figure 4. This will protect the AD1362 from possible damage caused by voltages in excess of ±1 volt between the ground systems which could occur if the key grounding card should be removed from the overall system. The device will operate properly with as much as ±200mV between grounds; however, this difference will be reflected directly as an input offset voltage.

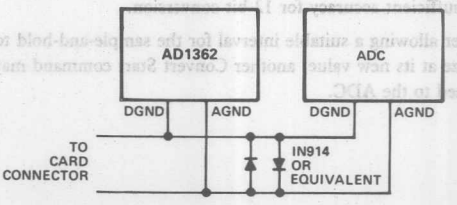

Figure 4. Ground-Fault Protection Diodes

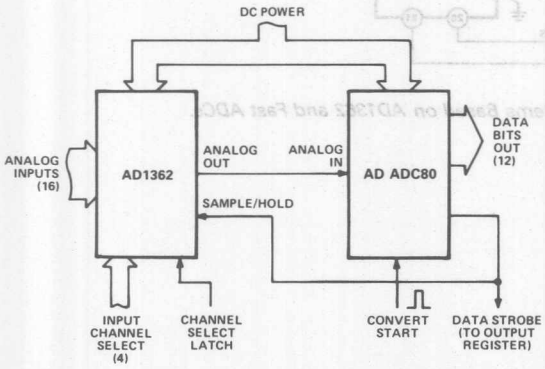
Power Supply Bypassing: The ±15V and +5V power leads should be capacitively bypassed to Analog Ground and Digital Ground respectively for optimum device performance. One microfarad tantalum types are recommended; these capacitors should be located close to the system. It is not necessary to shunt these capacitors with disk capacitors to provide additional high frequency power supply decoupling since each power lead is bypassed internally with a 0.039μF ceramic capacitor.

Interfacing to Popular Analog to Digital Converters

The AD1362 has been designed to interface directly to most analog to digital converters; often no additional components are required and only two interconnections must be made. The direct interface requirements for the ADC are as follows:

1. The ADC Status output must be positive-true Logic ("1" during conversion).
2. Transition from "0" to "1" must occur at least 200ns before the most significant bit decision is made (successive approximation ADC) or before input integration starts (integrating type ADC).
3. Status must not return to "0" before the LSB decision is made.
4. If Status is being used to latch output data, it must not return to Logic "0" until all output data bits are valid and available.



Complete system throughput performance is determined by combining the worst-case specifications of the AD1362 and the ADC. If guaranteed system performance is required, the AD363 and AD364 are recommended. The AD363 includes an AD1362 and an AD572 12-bit, 25-microsecond precision ADC. The AD364 consists of an AD1362 and an AD574 12-bit, microprocessor compatible, low cost ADC. Each is specified as a complete, two-package system.

Figure 5a shows the AD1362 driving an AD ADC80. The AD ADC80 is a 12-bit, 25-microsecond, low cost ADC that meets all of the requirements listed above. Throughput rate is typically 30kHz with no missing codes over the operating temperature range.

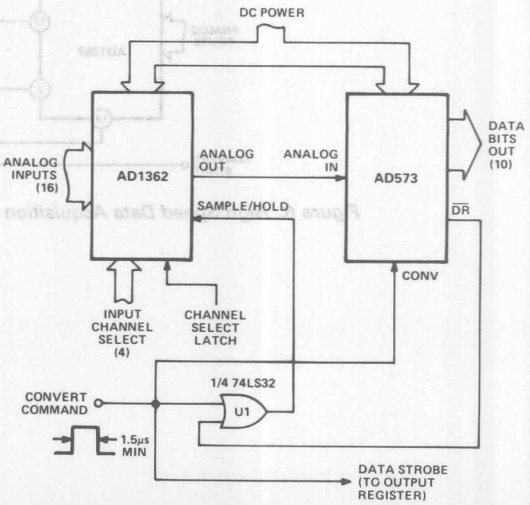


Figure 5b shows a 10-bit application based on the AD1362 and the AD573, a complete low cost 10-bit, 25-microsecond ADC. In this case, one of the above requirements is not met:

1. $\overline{DR}$ ($\overline{DATA\ READY}$), as Status, is positive-true, but . . .
2. $\overline{DR}$ does not indicate that a conversion is in progress until 1.5μs after conversion starts.

The gating provided by U1 allows the applied convert command (CC) to initiate input hold at the AD1362. CC must last for more than 1.5μs so that $\overline{DR}$ may then assume control of Hold.

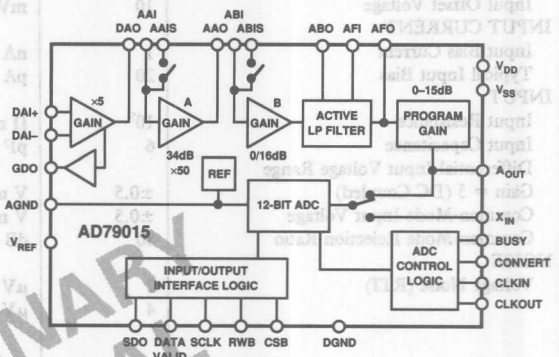
Data Acquisition System

AD79015



FEATURES

Functional Complete DAS
Single Package
Monolithic
High Impedance Differential Inputs
Guaranteed Low 1 nA Input Bias Current
Guaranteed 80 dB Common-Mode Rejection
External Selectable Bandpass Filter Frequencies
Software Programmable Gain Selection
12-Bit A/D Converter with On-Chip Reference
Serial Communication Interface
Data Sampling 40,000 Samples/Second
± 5 V Supplies
Low 175 mW (typ) Power Consumption
Small 28-Terminal Surface Mount Package (PLCC)

APPLICATION

Small Signal Data Acquisition
ECG Signal Data Acquisition
Patient Monitoring

FUNCTIONAL BLOCK DIAGRAM

GENERAL DESCRIPTION

The AD79015 is a complete data acquisition system for very small signals (i.e., biomedical ECG) with a data sampling rate of minimum 40,000 samples/sec. It provides high accuracy, high stability, and functional completeness in a single 28-pin package.

It includes a high performance instrumentation amplifier at the front-end, bandpass filter, and an accurate 12-bit ADC with on-chip reference.

An on-chip clock circuit is provided, which may be used with a crystal for stand-alone operation. Alternatively, the clock input may be driven from an external CMOS-compatible clock source such as a microprocessor clock.

The AD79015 serial interface is compatible with many microprocessors and digital signal processors such as the ADSP-2100, TMS32020, μPD7720, and DSP-56000. It can also be used with general purpose serial to parallel converters such as shift registers.

The AD79015 is fabricated in Analog Devices' linear compatible CMOS process (LC^2MOS), an advanced, all ion-implanted process that combines fast CMOS logic and linear, bipolar circuits on a single chip, thus achieving excellent linear performance while still retaining low CMOS power levels.

PRODUCT HIGHLIGHTS

1. Single chip, complete small signal DAS. It includes a high performance differential front end amplifier, programmable gain stages, externally controlled high and low corner frequencies, and a 12-bit AD converter with on-chip reference.
2. Input amplifier has extremely low input bias current of <1 nA over full temperature range. Typical input bias current at ambient temperature is 20 pA.
3. On-chip guard driver to minimize external components.
4. Software programmable gain setting with a gain range of 0 dB to 31 dB.
5. On-chip clock oscillator to minimize external components.
6. A serial interface is provided to make it easy to use AD79015 in applications where full isolation from the mains power is required.
7. Serial interface supports multichannel applications with minimal external components.
8. LC^2MOS circuitry gives low power drain (175 mW typ) from +5 V, and −5 V supplies.

PRELIMINARY TECHNICAL DATA

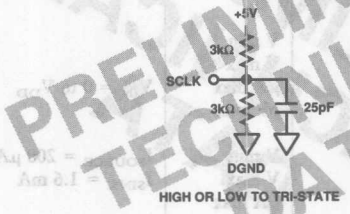
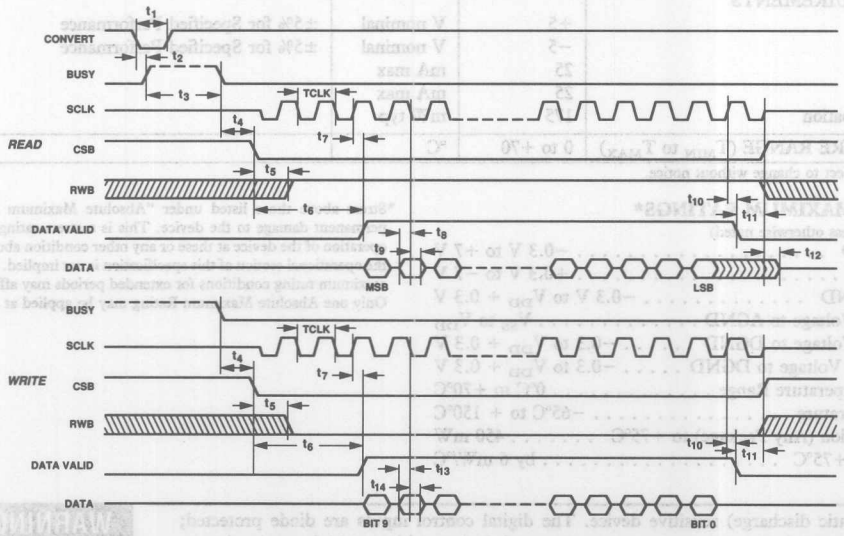
Derates above +75°C . . . . . by 6 mW/°C

*Stress above those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. This is a stress rating only and functional operation of the device at these or any other condition above those indicated in the operational section of this specification is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability. Only one Absolute Maximum Rating may be applied at any one time.

CAUTION



ESD (electrostatic discharge) sensitive device. The digital control inputs are diode protected; however, permanent damage may occur on unconnected devices subject to high energy electrostatic fields. Unused devices must be stored in conductive foam or shunts. The protective foam should be discharged to the destination socket before devices are removed.



This information applies to a product under development. Its characteristics and specifications are subject to change without notice. Analog Devices assumes no obligation regarding future manufacture unless otherwise agreed to in writing.

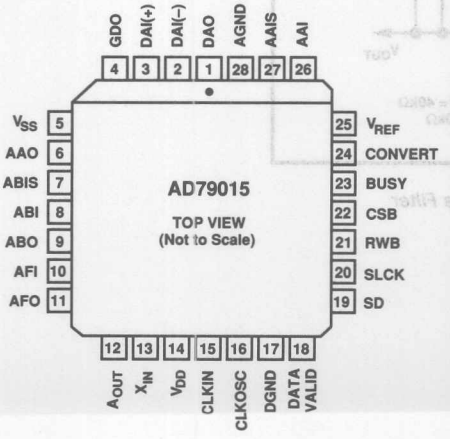
PIN FUNCTION DESCRIPTION



Pin	Mnemonic	Description
1	DAO	Differential Amplifier Out
2	DAI(−)	Differential Amplifier In (−)
3	DAI(+)	Differential Amplifier In (+)
4	GDO	Guard Drive Output
5	V_{SS}	Negative Supply, −5 V
6	AAO	Amplifier A Out
7	ABIS	Amplifier B In (Switched)
8	ABI	Amplifier B In
9	ABO	Amplifier B Out
10	AFI	Active Filter In (−)
11	AFO	Active Filter Out
12	A_{OUT}	Analog Out
13	X_{IN}	External ADC Input
14	V_{DD}	Positive Supply, +5 V
15	CLKIN	Clock Input Pin. An external TTL compatible clock may be applied to this pin
16	CLKOSC	Clock Oscillator Pin
17	DGND	Digital Ground
18	DATA VALID	This pin signals valid data in/out during SCLK low-high transition
19	SDO	Serial Data In/Out. This pin is in tristate when CSB is high
20	SCLK	Serial Clock Output. This pin is in tristate when CSB is high
21	RWB	Read/Write Select
22	CSB	Chip Select
23	BUSY	Converter Busy
24	CONVERT	Start Conversion
25	V_{REF}	Voltage Reference Out
26	AAI	Amplifier A In
27	AAIS	Amplifier A In (Switched)
28	AGND	Analog Ground

PIN CONFIGURATION

PLCC

This information applies to a product under development. Its characteristics and specifications are subject to change without notice. Analog Devices assumes no obligation regarding future manufacture unless otherwise agreed to in writing.

CIRCUIT INFORMATION

SIGNAL LEVELS

For an input gain of 5, the maximum Input Signal for Full-Scale ADC Output is ±10 mV.

INTERNAL CLOCK OSCILLATOR

Figure 1 shows the AD79015 internal clock circuit. A crystal or ceramic resonator may be connected as in Figure 1 to provide a clock oscillator for the internal timing. Alternatively, the crystal/resonator may be omitted and an external CMOS-compatible clock source connected to CLKIN. The mark/space ratio of the external clock must be in the range of 45/55 and 55/45. An inverted CLKIN signal will appear at the SCLK output pin.

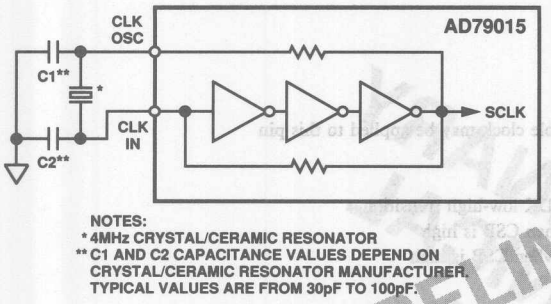

Figure 1. AD79015 Internal Clock Circuit

ACTIVE LOW-PASS FILTER

The internal active filter is implemented with a 2nd order negative feedback configuration.

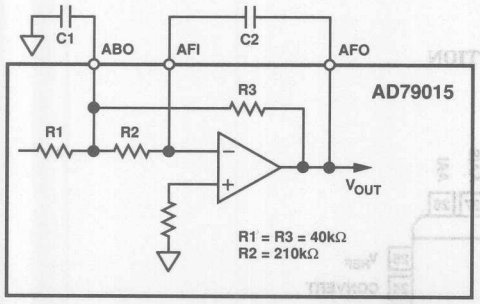

Figure 2. Low-Pass Filter

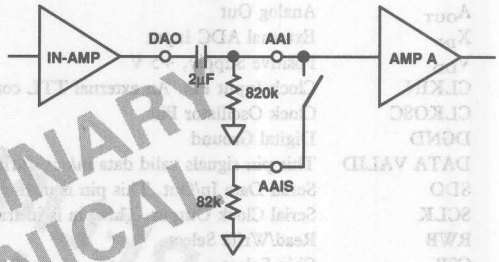
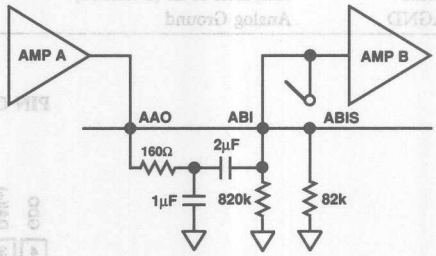


The filter cutoff frequency and filter damping factor are determined by selecting the appropriate values of C_1 and C_2. The resistor value for R1 and R3 is 40 kΩ and R2 is 210 kΩ.

$$d = \sqrt{\frac{C2}{C1}}\left[\sqrt{\frac{R2}{R3}} + \sqrt{\frac{R3}{R2}} + \sqrt{\frac{R2 \times R3}{R1}}\right] \quad gain = \frac{R3}{R1}$$

$$Bandpass\ ripple\ \frac{e_{OUT}}{e_{IN}} = -20\ log_{10}\left[\frac{d\sqrt{4-d^2}}{2}\right]$$



HIGH-PASS FILTER (Example Only)

This external high-pass filter can be implemented between the input gain stage and Amplifier A.

BAND PASS FILTER (Example Only)

This external band pass filter can be implemented between Amplifier A and Amplifier B.

PRELIMINARY TECHNICAL DATA

This information applies to a product under development. Its characteristics and specifications are subject to change without notice. Analog Devices assumes no obligation regarding future manufacture unless otherwise agreed to in writing.

PROGRAMMING THE AD79015

The function of the part is set by writing a ten-bit word to the control register on chip using the serial interface. The timing for the write operation is provided in the timing diagrams.

The order and function of the bits in the control register is as follows:

Bit 9	A "1" sets external input to the ADC.
Bit 8	Internal use only. Must be set to a "1."
Bit 7	Internal use only. Must be set to a "1."
Bit 3–Bit 6	A 4-bit binary code to set the gain of the programmable gain block between 0 dB and 15 dB in steps of 1 dB. "0000" is 0 dB and "1111" is 15 dB.
Bit 2	A "0" sets the gain of 3rd stage to 0 dB. A "1" sets the gain of 3rd stage to 16 dB.
Bit 1	A "1" closes the internal switches at the inputs to the 2nd and 3rd stage amplifiers.
Bit 0	Internal use only. Must be set to a "0."

Valid data available only after the first read from and write to the interface register

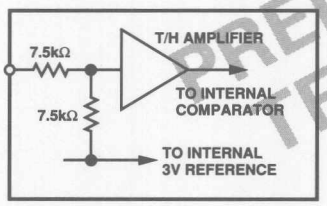


Figure 3. ADC Analog Input

ANALOG INPUT

Figure 3 shows the ADC analog input. The analog input range is 3 V into an input resistance of typically 15 kΩ. The designed code transition occurs midway between successive integer LSB values (i.e., 1/2 LSB, 3/2 LSBs, 5/2 LSBs . . . FS−3/2 LSBs). The output code is binary with 1 LSB = FS/4096 = 6 V/4096 = 1.46 mV. The ideal input/output transfer function is shown in Figure 4.

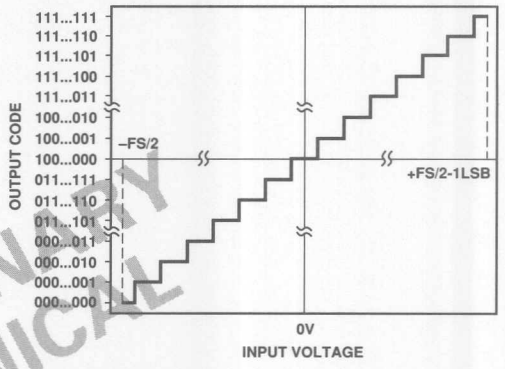

Figure 4. Bipolar Input/Output Transfer Function

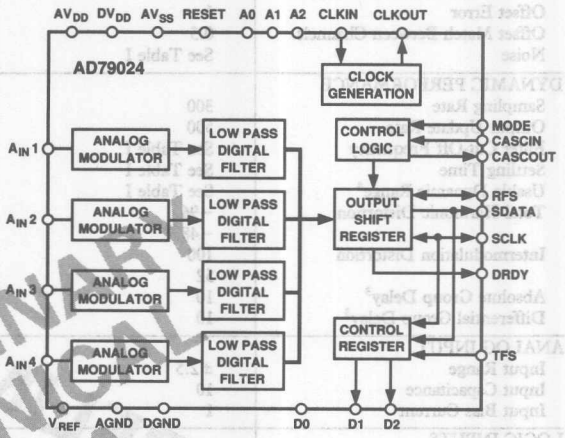
20-Bit Data Acquisition System

AD79024

FEATURES

20-Bit Sigma-Delta ADC
- Dynamic Range of 105 dB (150 Hz Input)
- ±0.0015% Integral Nonlinearity (150 Hz Input)

On-Chip Low-Pass Digital Filter
- Cut-Off Programmable from 300 Hz to 18.75 Hz
- Linear Phase Response



Five Line Serial I/O
Easy Interface to DSPs and Microcomputers
Software Control of Filter Cut-Off
±5 V Supply
Low Power Operation: 50 mW

APPLICATIONS

Biomedical Data Acquisition Systems
- ECG Machines
- EEG Machines

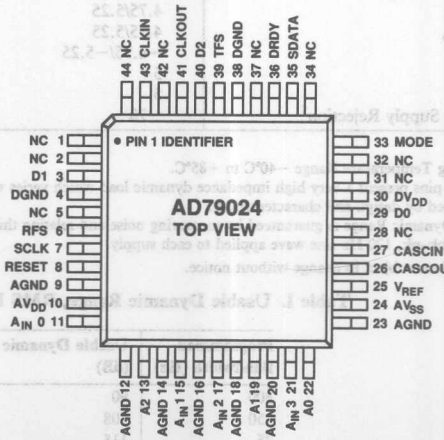
Process Control Systems
High Accuracy Measurement Systems

FUNCTIONAL BLOCK DIAGRAM

GENERAL DESCRIPTION

The AD79024 is a Signal Processing Block for Data Acquisition Systems. It is particularly suitable for biomedical applications like ECG and EEG machines. The device is capable of processing 4 channels with bandwidths of up to 300 Hz. Resolution is 20 bits, and the usable dynamic range varies from 115 dB with an input bandwidth of 18.75 Hz to 90 dB with an input bandwidth of 300 Hz.

The required system low-pass filtering is inherent in the sigma delta technique. This eliminates front-end filtering.



Three address pins program the device address. This allows a data acquisition system with up to 32 channels to be set up in a simple fashion. The output word from the device contains 32 bits of data. One bit is determined by the state of the D0 input and may be used with an external Pacemaker Detect Circuit to indicate that the output word is invalid because of the presence of a pacemaker pulse. There are 20 bits of data. Two bits contain the channel address, and 3 bits are the device address. Thus, each channel in a 32-channel system would have a discrete 5-bit address. The device also has a CASCOUT pin and a CASCIN pin which allow simple networking of multiple devices.

The on-chip Control Register is programmed using the SCLK, SDATA and TFS pins. Three bits of the Control Register set the Digital Filter Cut-Off Frequency for the device. Selectable frequencies are 300 Hz, 150 Hz, 75 Hz, 37.5 Hz and 18.75 Hz. A further 2 bits appear as outputs D1 and D2 and can be used for controlling calibration at the front end. The device is available in a 44-pin plastic QFP (Quad Flat Pack) package.

The AD79024 is fabricated in Analog Devices' Linear Compatible CMOS process (LC²MOS), an advanced, all ion-implanted process that combines fast CMOS logic and linear, bipolar circuits on a single chip, thus achieving excellent linear performance while still retaining low CMOS power levels.

PIN CONFIGURATION

Plastic QFP

NOTE: PIN 16–AGND IS THE PRIMARY AGND TO THE PART. SECONDARY AGND PINS ARE USED TO ISOLATE THE ANALOG INPUT PINS. NC PINS MAY BE CONNECTED TO EITHER DIGITAL SUPPLY OR LEFT UNCONNECTED.

PRELIMINARY TECHNICAL DATA

This information applies to a product under development. Its characteristics and specifications are subject to change without notice. Analog Devices assumes no obligation regarding future manufacture unless otherwise agreed to in writing.

50 Hz Sine Wave; A_{IN} Source Resistance = 750 Ω with 1 nF to AGND at each A_{IN}. I_A = I_{MIN} to I_{MAX}, unless otherwise stated.)

PRELIMINARY TECHNICAL DATA

NOTES
[1]Operating Temperature Range −40°C to +85°C.
[2]The A_{IN} pins present a very high impedance dynamic load which varies with clock frequency.
[3]Guaranteed by design and characterization.
[4]Usable Dynamic Range is guaranteed by measuring noise and relating this to the Full-Scale Input Range.
[5]100 mV pk–pk, 120 Hz sine wave applied to each supply.
Specifications subject to change without notice.

Table I. Usable Dynamic Range, RMS Noise and Filter Settling Time vs. Filter Bandwidth

Programmed Bandwidth (Hz)	Usable Dynamic Range (dB)	RMS Noise (μV)	Filter Settling Time to ±0.0007% FS (ms)
300	90	56	5
150	108	7	10
75	115	3	20
37.5	115	3	40
18.75	115	3	80

NOTE
Usable Dynamic Range is defined as the ratio of the rms full-scale reading (sine wave input) to the rms noise of the converter.

This information applies to a product under development. Its characteristics and specifications are subject to change without notice. Analog Devices assumes no obligation regarding future manufacture unless otherwise agreed to in writing.

Timing Characteristics[1, 2] (AV_{DD} = DV_{DD} = +5 V ± 5%; AV_{SS} = −5 V ± 5%; AGND = DGND = 0 V; f_{CLKIN} = 4 MHz; Input Levels: Logic 0 = 0 V, Logic 1 = DV_{DD}; unless otherwise stated.)

Parameter	Limit @ T_{MIN}, T_{MAX}	Units	Conditions/Comments
f_{CLKIN}[3, 4]	400	kHz min	Master Clock Frequency: Internal Gate Oscillator
	4	MHz max	
	400	kHz min	Master Clock Frequency: Externally Supplied
	4	MHz max	
t_R[5]	50	ns max	Digital Output Rise Time; Typically 20 ns
t_F[5]	50	ns max	Digital Output Fall Time; Typically 20 ns

t_5	10	ns min	SDATA Hold Time
t_6	20	ns min	TFS Hold Time
Master Mode Timing			
t_7	200	ns min	CASCIN Pulse Width
t_8[6]	25	ns max	CASCIN High to SCLK Valid Delay
t_9	500	ns min	SCLK Period
t_{10}	150	ns min	SCLK Width
t_{11}	25	ns max	SCLK High to RFS High Delay
t_{12}	0	ns min	RFS Hold After SCLK High
t_{13}[7]	100	ns max	SCLK High to SDATA Valid
t_{14}[8]	250	ns max	SCLK Falling Edge to Hi-Z Delay
t_{15}	25	ns max	SCLK Hi-Z to CASCOUT High Delay
t_{16}	500	ns min	CASCOUT Pulse Width
Slave Mode Timing			
t_7	200	ns min	CASCIN Pulse Width
t_{16}	500	ns min	CASCOUT Pulse Width
t_{17}	100	ns min	CASCIN High to SCLK High Setup Time
t_{18}	250	ns min	SCLK Period
t_{19}	77	ns min	SCLK Width
t_{20}	50	ns min	RFS to SCLK High Setup Time
t_{21}	10	ns min	RFS Hold Time After SCLK Low
t_{22}[7]	100	ns max	SCLK High to SDATA Valid
t_{23}[8]	250	ns max	SCLK Falling Edge to Hi-Z Delay.
t_{24}	50	ns max	SCLK Low to CASCOUT High Delay

PRELIMINARY TECHNICAL DATA

NOTES
[1]Sample tested at +25°C to ensure compliance. All input signals are specified with tr = tf = 5 ns (10% to 90% of 5 V) and timed from a voltage level of 1.6 V.
[2]See Figures 1 to 6.
[3]CLKIN Duty Cycle range is 20% to 80%.
[4]The AD79024 is production tested with f_{CLKIN} at 4 MHz. It is guaranteed by characterization to operate at 400 kHz.
[5]Specified using 10% and 90% points on waveform of interest.
[6]If DRDY is high when a rising edge occurs on CASCIN, the rising edge will not be recognized until DRDY goes low to indicate that the output register can be read.
[7]t_{13} and t_{22} are measured with the load circuit of Figure 1 and defined as the time required for an output to cross 0.8 V or 2.4 V.
[8]t_{14} and t_{23} are derived from the measured time taken by the data outputs to change 0.5 V when loaded with the circuit of Figure 1. The measured number is then extrapolated back to remove the effects of charging or discharging the 100 pF capacitor. This means that the time quoted in the Timing Characteristics is the true bus relinquish time of the part and as such is independent of external bus loading capacitances.

This information applies to a product under development. Its characteristics and specifications are subject to change without notice. Analog Devices assumes no obligation regarding future manufacture unless otherwise agreed to in writing.

*Stresses above those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. This is a stress rating only and functional operation of the device at these or any other conditions above those listed in the operational sections of this specification is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

CAUTION

ESD (electrostatic discharge) sensitive device. The digital control inputs are diode protected; however, permanent damage may occur on unconnected devices subject to high energy electrostatic fields. Unused devices must be stored in conductive foam or shunts. The protective foam should be discharged to the destination socket before devices are inserted.

PRELIMINARY TECHNICAL DATA

PIN DESCRIPTION

Pin	Description
AV_{DD}	Analog Positive Supply, +5 V nominal.
DV_{DD}	Digital Positive Supply, +5 V nominal.
AV_{SS}	Analog Negative Supply, −5 V nominal.
RESET	A high pulse on this pin synchronizes the sampling point on the four input channels. It can be used in a multichannel system to ensure simultaneous sampling.
A0–A2	The three address pins, A0, A1 and A2 give the device a unique address. This information is contained in the output data stream from the device.
CLKIN	Clock Input for External Clock.
CLKOUT	Clock Output which is used to generate an internal master clock by connecting a crystal between CLKOUT and CLKIN. If an external clock is used, then CLKOUT is not connected.
MODE	This digital input determines the device interface mode. If it is hardwired low then the Master Mode interface is enabled; whereas if it is high, the Slave Mode interface is enabled.
CASCIN	Positive-edge triggered digital input which is used to enable the output data stream. This input is used to cascade several devices in a multichannel system.
CASCOUT	Digital output which goes high at the end of a complete 4-channel data transfer. This can be connected to the CASCIN of the next device in a multi-channel system to ensure proper control of the data transfer.
RFS	Receive Frame Synchronization signal for the serial output data stream. This can be an input or output depending on the interface mode.
SDATA	Serial Data Input/Output pin.
SCLK	Serial Clock Input/Output. The SCLK pin is configured as an input or output, depending on the state of the Mode pin.
DRDY	Data Ready Output. DRDY is low when valid data is available in the output register. It goes high for four clock cycles when a new word is being loaded into the output register, to indicate that valid data is not available.
TFS	Transmit Frame Sync input for programming the on-chip Control Register.
D0	Digital Data Input. This is contained in the digital data stream sent from the device.
D1, D2	Digital Outputs. These two digital outputs can be programmed from the on-chip Control Register. They can be used to switch in calibration signals at the front end.
V_{REF}	Reference Input, nominally 2.5 V.
AGND	Analog Ground. Ground reference for analog circuitry.
DGND	Digital Ground. Ground return for digital circuitry.
$A_{IN}1$–$A_{IN}4$	Analog Input pins. The analog input range is ±2.5 V.

This information applies to a product under development. Its characteristics and specifications are subject to change without notice. Analog Devices assumes no obligation regarding future manufacture unless otherwise agreed to in writing.

DESCRIPTION OF OPERATION

Voltage Reference

Full scale analog input corresponds to reference voltage input.

The reference input presents exactly the same dynamic load as the analog input, but in the case of the reference input, source resistance and long settling time introduce gain errors rather than offset errors. Most precision references however have sufficiently low output impedance and wide enough bandwidth to settle to the required accuracy in the time allowed by the AD79024.

The reference should be chosen to have minimal noise in the programmed passband. Recommended references are the AD580, AD680 or the ADREF-43 from Analog Devices. These low noise references have a typical noise spectral density of 40 nV/$\sqrt{\text{Hz}}$ at 300 Hz.

Clock Generation

The device operates from a master clock which must be provided either from a crystal source or an external clock source. If a crystal is used, it must be connected across the CLKIN and CLKOUT pins. An external clock can be used by driving the CLKIN input directly with a CMOS compatible clock. In this case, CLKOUT is left unconnected. The nominal clock frequency for the device is 4.096 MHz.

Control Register Description

The 16-bit control register is programmed in two 8-bit bytes. Three control lines are used: TFS, SCLK and SDATA. SCLK can be an input or an output depending on the state of the MODE pin. When this is low, SCLK is an output (Master Mode); and when it is high, SCLK is an input (Slave Mode). When TFS goes low, data on the SDATA line is clocked into the control register on each succeeding falling edge of SCLK.

When 8 bits have been clocked in, the transfer automatically stops. Only when another negative going edge is detected on TFS will new information be written into the control register. The control register programming model is shown in Table II. Bits DB8 and DB0 allow the control register to identify whether the MS Byte or the LS Byte has been programmed. Only when DB8 is a 1 and DB0 is a 0 will the register recognize that a complete valid word has been programmed.

Control Register bit, A3, acts as an extra address bit which must always be set to 1 to enable programming of the AD79024. If it is set to 0 then the programmed word is ignored. This allows the user to bypass the AD79024 control register and use the serial stream from the DSP or microcomputer to program other serial peripheral devices.

When a valid word has been received, the device interrogates the mode bit, M0. If this is 0, then the digital filter cut-off frequencies are programmed to the appropriate value if the device address pins correspond to the A2, A1, A0 bits in the control register. If the device address pins do not correspond to the A2, A1, A0 bits, then the FC2, FC1, FC0 bits are ignored. If M0 is 1, then the digital filter cut-off frequencies are programmed to the FC2, FC1, FC0 value irrespective of the address bits. In a multichannel system this allows the user to either program all AD79024s to have the same cut-off frequency or else to give each device a separate cut-off frequency.

Control Register bits FC2, FC1, FC0 program the digital filter cut-off frequency (see Table IV).

Control Register bits D2, D1 control the digital output Pins D2 and D1. These are programmed in the same way as FC2, FC1, FC0.

PRELIMINARY TECHNICAL DATA

Table II. Control Register Programming Model

DB15	DB14	DB13	DB12	DB11	DB10	DB9	DB8	DB7	DB6	DB5	DB4	DB3	DB2	DB1	DB0
A3	A2	A1	A0	M0	FC2	FC1	1	FC0	D2	D1	X	X	X	X	0

Table III. M0 Truth Table

M0	Operating Mode
0	Initialization Mode 0. A2, A1, A0 determine which device is addressed and programmed with cut-off frequency and digital output.
1	Initialization Mode 1. A2, A1, A0 ignored. All devices are addressed and programmed with common cut-off frequency and digital output.

Reset

The AD79024 has a hardware reset which can be used to synchronize many devices. When the RESET pin goes low after being high for at least 4 CLKIN cycles, the modulator sampling points and digital filter starting points are all synchronized. This synchronizes all devices which receive the RESET pulse and gives simultaneous sampling of all channels.

Data Output Interface Modes

When the control register has been programmed, the device begins conversion. There is an initial delay of 400,000 master clock cycles to allow the digital filters to settle. These filters are $Sinc^3$ and so the filter output update rate is directly related to the programmed cut-off frequency. The ratio between these is 3.81. So, for a filter cut-off frequency of 300 Hz, the output update is 1.145 kHz. The falling edge of the DRDY output indicates that the output shift register has been updated. There are two interface modes. One is the Master Mode where the AD79024 is the master in the system and the processor to which it is communicating is the slave. The other mode is the Slave Mode where the AD79024 is the slave and the processor is the system master. In both of these modes the data output stream contains 4 × 32 bits corresponding to the four input channels. The output data format is given in Table V, and the channel address format is given in Table VI.

Master Mode Interface

In this mode, data is clocked out of the AD79024 by an internally generated serial clock and frame synchronization pulse. Two signals initiate the transfer. These are the input CASCIN* and the internally generated DRDY signal. When a rising edge is detected on CASCIN, the device checks the state of DRDY. Note, that on initial power-up or after a reset has been applied, the CASCIN input is not necessary on device 000 for the first data transfer but is required thereafter.

If DRDY is low, then the 3-state output, RFS, goes high on the next rising edge of CLKIN and stays high for two CLKIN cycles before going low again. The 3-state SCLK output is also activated on the same rising edge. As RFS goes low, DB31 is clocked out on the rising edge of SCLK. Data is transmitted in 16-bit words. For each A_{IN}, there are two 16-bit words and two RFS signals. When DB0 of $A_{IN}4$ has been clocked out, SCLK goes back into 3-state and the CASCOUT output goes high for two master clock cycles. DRDY also goes high at this point. Successive devices can be networked together by tying the CASCOUT of one device to the CASCIN on the next one.

The Master Mode interface is very suitable for loading data into a serial-to-parallel shift register or for DSPs like the ADSP-2101 which can accept a continuous stream of 16-bit words.

Slave Mode Interface

In this mode, the master processor controls the transfer of data from the signal processing block. It starts the transfer by sending a frame synchronization pulse and serial clock to the AD79024. This could be in response to an interrupt generated by the DRDY output on the AD79024. If the device has detected a rising edge on CASCIN or is device 000 on its first transfer, it starts to send out data on the next rising edge of SCLK. When all the data bits have been clocked out, the CASCOUT pin goes high for two CLKIN cycles and DRDY also goes high. If the device is still transmitting data when a new word becomes available, the old data will continue to be transmitted and the new data is lost.

The Slave Mode interface is suited to both microcomputers like the 8051 and 68HC11 and also DSPs like the TMS320C25, ADSP-2101 and 56000.

Reset

The AD7902A has a hardware reset which can be used to synchronize many devices. When the RESET pin goes low after being high for at least 4 CLKIN cycles, the modulator sampling points and digital filter starting points are all synchronized. This synchronizes all devices which receive the RESET pulse and gives simultaneous sampling of all channels.

Data Output Interface Modes

When the control register has been programmed, the device begins conversion. There is an initial delay of 400,000 master clock cycles to allow the digital filters to settle. These filters are $Sinc^3$ and so the filter output update rate is directly related to the programmed cut-off frequency. The ratio between these is 3.81. So, for a filter cut-off frequency of 300 Hz, the output update is 1.145 kHz. The falling edge of the DRDY output indicates that the output shift register has been updated. There are two interface modes. One is the Master Mode where the AD7902A is the master in the system and the processor to which it is communicating is the slave. The other mode is the Slave Mode where the AD7902A is the slave and the processor is the system master. In both of these modes the data output stream contains 4 × 32 bits corresponding to the four input channels. The output data format is given in Table V, and the channel address format is given in Table VI.

Master Mode Interface

In this mode, data is clocked out of the AD7902A by an internally generated serial clock and framing/synchronizing pulse. Two signals initiate the transfer. These are the input CASCIN and the internally generated DRDY signal. When a rising edge is detected on CASCIN, the device checks the state of DRDY. Note, that on initial power-up or after a reset has been applied the CASCIN input is not necessary on device 000 for the first data transfer but is required thereafter.

If DRDY is low, then the 3-state output, RFS, goes high on the next rising edge of CLKIN and stays high for two CLKIN cycles before going low again. The 3-state SCLK output is also activated on the same rising edge. As RFS goes low, DB31 is clocked out on the rising edge of SCLK. Data is transmitted in 16-bit words. For each A_{DD} there are two 16-bit words and two RFS signals. When DB0 of $A_{DD}4$ has been clocked out, SCLK goes back into 3-state and the CASCOUT output goes high for two master clock cycles. DRDY also goes high at this point. Successive devices can be networked together by tying the CASCOUT of one device to the CASCIN on the next one.

The Master Mode interface is very suitable for loading data into a serial-to-parallel shift register or for DSPs like the ADSP-2101 which can accept a continuous stream of 16-bit words.

Slave Mode Interface

In this mode, the master processor controls the transfer of data from the signal processing block. It starts the transfer by sending a framing synchronization pulse and serial clock to the AD7902A. This could be in response to an interrupt generated by the DRDY output on the AD7902A. If the device has detected a rising edge on CASCIN or it is device 000 on its first transfer, it sets its second out data on the next rising edge of SCLK. When all the data bits have been clocked out, the CASCOUT pin goes high for two CLKIN cycles and DRDY also goes high. If the device is still transmitting data when a new word becomes available, the old data will continue to be transmitted and the new data is lost.

The Slave Mode interface is suited to both microcomputers like the 8051 and 68HC11 and also DSPs like the TMS320C25, ADSP-2101 and 56000.

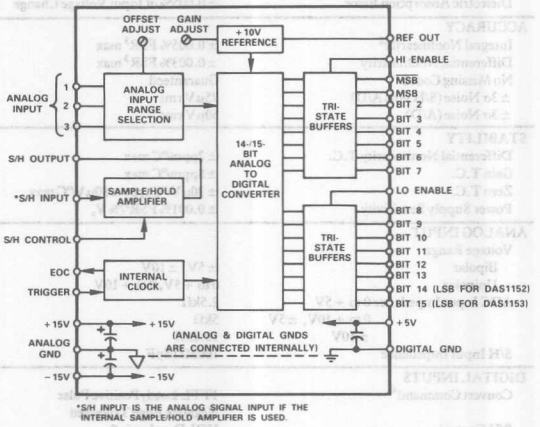
14-Bit & 15-Bit Sampling Analog-to-Digital Converters

DAS1152/DAS1153



FEATURES

- Complete with High Accuracy Sample/Hold and A/D Converter
- Differential Nonlinearity: ±0.002% FSR max (DAS1153)
- Nonlinearity: DAS1152: ±0.005% FSR max
  DAS1153: ±0.003% FSR max
- Low Differential Nonlinearity T.C.: ±2ppm/°C max
- High Throughput Rate: 25kHz min (DAS1152)
- High Feedthrough Rejection: −96dB
- Byte-Selectable Tri-State Buffered Outputs
- Internal Gain & Offset Potentiometers
- Improved Second Source to A/D/A/M 824 and A/D/A/M 825 Modules

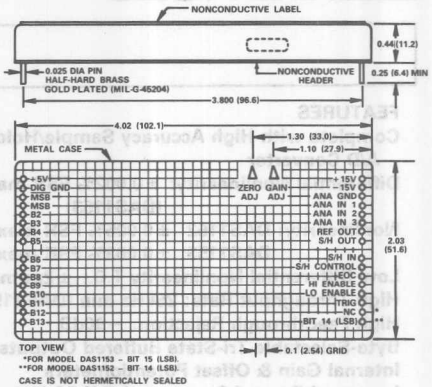
APPLICATIONS

- Process Control Data Acquisition
- Automated Test Equipment
- Seismic Data Acquisition
- Nuclear Instrumentation
- Medical Instrumentation
- Robotics

FUNCTIONAL BLOCK DIAGRAM

GENERAL DESCRIPTION

The DAS1152/DAS1153 are 14-/15-bit sampling analog-to-digital converters having a maximum throughput rate of 25kHz/20kHz. They provide high accuracy, high stability, and functional completeness all in a 2″ × 4″ × 0.44″ metal case.



Guaranteed high accuracy system performance such as nonlinearity of ±0.005% FSR (DAS1152)/±0.003% FSR (DAS1153) and differential nonlinearity of ±0.003% FSR (DAS1152)/±0.002% FSR (DAS1153) are provided. Guaranteed stability such as differential nonlinearity T.C. of ±2ppm/°C (DAS1153) maximum, zero T.C. of ±80μV/°C maximum, gain T. C. of ±8ppm/°C maximum and power supply sensitivity of ±0.001% FSR/% V_S are also provided by the DAS1152/DAS1153.

The DAS1152/DAS1153 make extensive use of both integrated circuit and thin film components to obtain their excellent performance, small size, and low cost. The devices contain a precision sample/hold amplifier, high accuracy 14-/15-bit analog-to-digital converter, tri-state output buffers, internal gain and offset trim potentiometers, and power supply bypass capacitors (as shown in Figure 1).

Four analog input voltage ranges are selectable via user pin programming: 0 to +5V, 0 to +10V, ±5V, and ±10V. Unipolar coding is provided in true binary format with bipolar coding displayed in offset binary and two's complement. Tri-state buffers provide easy interface to bus structured applications.

*FOR MODEL DAS1153 – BIT 15 (LSB).
**FOR MODEL DAS1152 – BIT 14 (LSB).
CASE IS NOT HERMETICALLY SEALED

NOTES
*Specifications same as DAS1152
[1]Measured in hold mode, input 20V pk-pk @ 10kHz.
[2]Worst-case summation of S/H and A/D nonlinearity errors.
[3]FSR means Full Scale Range.
[4]When connecting the Convert Command and the S/H control terminals together, the pulse width must be long enough for the S/H amplifier to acquire the input signal to the required accuracy 4µs (max, DAS1152)/5µs (max, DAS1153). If the A/D converter is only used, the Convert Command pulse width should be 100ns min (see Figure 2).
[5]If only the ADC portion is used, the operating power supply voltage can be maintained at ±12V to ±17V. But if the S/H section is required, the operating voltage must be maintained at ±15V (±3%) or the S/H input voltage must be limited to −7V to +10V for a ±12V supply voltage.
[6]Recommended Power Supply: Analog Devices Model 923.
Specifications subject to change without notice.

ASSEMBLY INSTRUCTIONS

CAUTION: This module is not an embedded assembly and is not hermetically sealed. Do not subject to a solvent or water-wash process that would allow direct contact with free liquids or vapors. Entrapment of contaminants may occur, causing performance degradation and permanent damage. Install after any clean/wash process and then only spot clean by hand.

The DAS1152/DAS1153 are functionally complete data acquisition subsystems being fully characterized as such. All the necessary data acquisition and microprocessor interface elements are provided internal to these devices. Accuracy and performance criteria are tested and specified for the entire system. Thus, design time and associated high accuracy problems are minimized because layout and component optimization have already been performed.

For operation, the only connections necessary to the DAS1152/DAS1153 are the ±15V and +5V power supplies, analog input signal, trigger pulse, and the HI-ENABLE/LO-ENABLE tri-state controls. Analog input and digital output programming are user selectable via external jumper connections.

ANALOG INPUT SECTION

The analog input can be applied to just the A/D converter or to the internal sample/hold amplifier ahead of the A/D converter. When using just the A/D converter, apply the analog input per the voltage range pin programming shown in Table I. When using the sample/hold amplifier in conjunction with A/D converter, apply the analog input to the S/H INPUT terminal and connect the S/H OUTPUT terminal to the appropriate A/D converter analog input.

Table I. Analog Input Pin Programming

Analog Voltage Input Range	Connect V_{IN} or S/H Out To	Connect Analog Common To	Connect Ref Out To
0 to +5V	ANA IN 1, ANA IN 2, ANA IN 3	Ground	NC*
0 to +10V	ANA IN 2 ANA IN 3	Ground ANA IN 1	NC*
±5V	ANA IN 1	Ground, ANA IN 3	ANA IN 2
±10V	ANA IN 3	Ground, ANA IN 1	ANA IN 2

*No Connection

Errors due to source loading are eliminated since the sample/hold amplifier is a high-impedance unity-gain amplifier. High feedthrough rejection is provided for either single-channel or multichannel applications. Feedthrough rejection can be optimized, in multichannel applications, by changing channels at the rising or falling edge of the S/H control pulse.

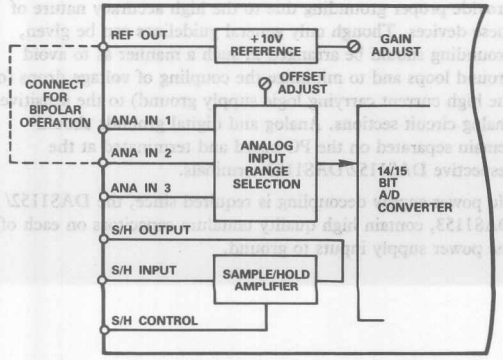

Figure 2. Analog Input Block Diagram

The timing diagram for the DAS1152/DAS1153 is illustrated in Figure 3. This figure also includes the sample/hold amplifier acquisition time.

If the sample/hold amplifier is required, the TRIGGER input and S/H CONTROL terminal can be tied together providing only one conversion control signal. When the trigger pulse goes high, it places the sample/hold amplifier in the sample mode allowing it to acquire the present input signal. The trigger pulse must remain high for a minimum of 4μs (DAS1152)/5μs (DAS1153) to insure accuracy is attained. If the sample/hold amplifier is not used, the trigger pulse needs to be only 100ns (min) in length to satisfy the A/D converter trigger requirements. At the falling edge of the trigger pulse, the sample/hold amplifier is placed in the hold mode, the A/D conversion begins, and all internal logic is reset. Once the conversion process is initiated, it cannot be retriggered until after the end of conversion.

With this negative edge of the trigger pulse the MSB is set low with the remaining digital outputs set to logic high state, and the status line is set high and remains high through the full conversion cycle. During conversion each bit, starting with the MSB, is sequentially switched low at the rising edge of the internal clock. The DAC output is then compared to the analog input and the bit decision is made. Each comparison lasts one clock cycle with the complete 14-/15-bit conversion taking 35μs/44μs maximum for the DAS1152/DAS1153 respectively. At this time, the STATUS line goes low signifying that the conversion is complete. For microprocessor bus applications, the digital output can now be applied to the data bus by enabling the tri-state buffers. For maximum data throughput, the digital output data should be read while the sample/hold amplifier is acquiring the new analog input signal.

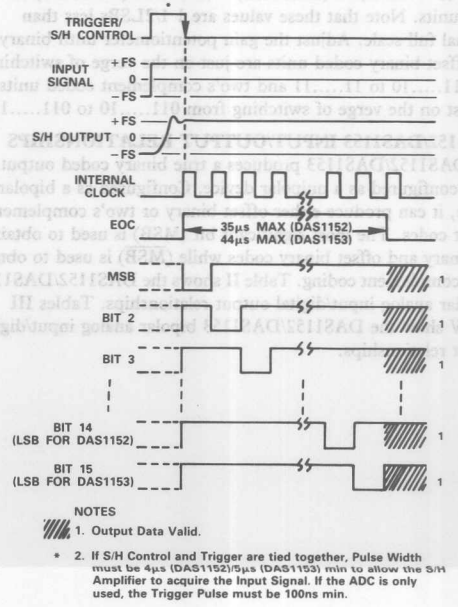

Figure 3. DAS1152/DAS1153 Timing Diagram

GAIN AND OFFSET ADJUSTMENT

The DAS1152/DAS1153 contain internal gain and offset adjustment potentiometers. Each potentiometer has ample adjustment range so that gain and offset errors can be trimmed to zero.

Since offset calibration is not affected by changes in gain calibration, it should be performed prior to gain calibration. Proper gain and offset calibration requires great care and the use of extremely sensitive and accurate reference instruments. The voltage standard used as a signal source must be very stable and be capable of being set to within ±1/10LSB of the desired value at any point within its range.

OFFSET CALIBRATION

For a 0 to +10V unipolar range set the input voltage precisely to +305μV for the DAS1152 and +153μV for the DAS1153. For a 0 to +5V unipolar range set the input to +153μV for the DAS1152 and +76μV for the DAS1153. Then adjust the zero potentiometer until the converter is just on the verge of switching from 000.....000 to 000.....001.

For the ±5V bipolar range set the input voltage precisely to +305μV for the DAS1152 and +153μV for the DAS1153. For a ±10V bipolar range set the input voltage precisely to +610μV for the DAS1152 and +305μV for the DAS1153. Adjust the zero potentiometer until the offset binary coded units are just on the verge of switching from 000.....000 to 000.....001 and the two's complement coded units are just on the verge of switching from 100.....000 to 100.....001.

GAIN CALIBRATION

Set the input voltage precisely to +9.99909V (DAS1152)/ +9.99954V (DAS1153) for the 0 to +10V units, +4.99954V (DAS1152)/+4.99977V (DAS1153) for 0 to +5V units, +9.99817V (DAS1152)/+9.99909V (DAS1153) for ±10V units, or +4.99909V (DAS1152)/+4.99954V (DAS1153) for ±5V units. Note that these values are 1 1/2LSBs less than nominal full scale. Adjust the gain potentiometer until binary and offset binary coded units are just on the verge of switching from 11.....10 to 11.....11 and two's complement coded units are just on the verge of switching from 011.....10 to 011.....11.

DAS1152/DAS1153 INPUT/OUTPUT RELATIONSHIPS

The DAS1152/DAS1153 produces a true binary coded output when configured as a unipolar device. Configured as a bipolar device, it can produce either offset binary or two's complement output codes. The most significant bit (MSB) is used to obtain the binary and offset binary codes while ($\overline{\text{MSB}}$) is used to obtain two's complement coding. Table II shows the DAS1152/DAS1153 unipolar analog input/digital output relationships. Tables III and IV show the DAS1152/DAS1153 bipolar analog input/digital output relationships.

NOMINAL BIPOLAR INPUT-OUTPUT RELATIONSHIPS

+0.00000V	+0.00000V	100 000 000 000 000	000 000 000 000 000
−5.00000V	−10.00000V	000 000 000 000 000	100 000 000 000 000

TRI-STATE DIGITAL OUTPUT

The ADC digital outputs are provided in parallel format to the output tri-state buffers. The output information can be applied to a data bus in either a one-byte or a two-byte format by using the HIGH BYTE ENABLE and LOW BYTE ENABLE terminals. If the tri-state feature is not required, normal digital outputs can be obtained by connecting the enable pins to ground.

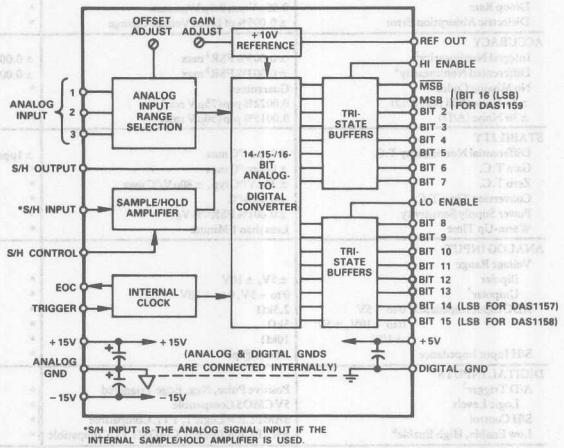
POWER SUPPLY AND GROUNDING CONNECTIONS

Although the analog power ground and the digital ground are connected in the DAS1152/DAS1153, care must still be taken to provide proper grounding due to the high accuracy nature of these devices. Though only general guidelines can be given, grounding should be arranged in such a manner as to avoid ground loops and to minimize the coupling of voltage drops (on the high current carrying logic supply ground) to the sensitive analog circuit sections. Analog and digital grounds should remain separated on the PC board and terminated at the respective DAS1152/DAS1153 terminals.

No power supply decoupling is required since, the DAS1152/ DAS1153, contain high quality tantalum capacitors on each of the power supply inputs to ground.

Low Power 14-Bit, 15 Bit & 16-Bit Sampling Analog-to-Digital Converters

DAS1157/DAS1158/DAS1159



FEATURES

- Complete with High Accuracy Sample/Hold and A/D Converter
- Low Power Consumption: 650mW max, $V_S = \pm 15V$
- Rated Performance: −25°C to +85°C
- Low Nonlinearity (DAS1158 and DAS1159)
  - Differential: ±0.0015% FSR max
  - Integral: ±0.003% FSR max
  - Differential T.C.: ±1ppm/°C max
- High Throughput Rate: 18kHz min
- Byte-Selectable Tri-State Buffered Outputs
- Internal Gain & Offset Potentiometers
- Improved Second Source to A/D/A/M-834 and A/D/A/M-835 Modules

APPLICATIONS

- Seismic Data Acquisition
- Portable Field Instrumentation
- Automated Test Equipment
- Process Control Data Acquisition
- Medical Instrumentation

FUNCTIONAL BLOCK DIAGRAM

GENERAL DESCRIPTION

The DAS1157/DAS1158/DAS1159 are 14-/15-/16-bit sampling analog-to-digital converters. They are ideally suited for use in portable and remote data acquisition equipment where low power consumption (650mW maximum) and wide temperature range (−25°C to +85°C rated performance) are required.

DAS1157/DAS1158/DAS1159 provide guaranteed high accuracy and high stability system performance essential to medical, analytical and process control equipment: differential nonlinearity of ±0.0015% max and integral nonlinearity of ±0.003% max (DAS1158 and DAS1159); no missing codes guaranteed; gain T.C. of ±8ppm/°C max, zero T.C. of ±80μV/°C max and differential nonlinearity T.C. of ±1ppm/°C max.

The wide dynamic range will enhance the performance of critical measurements in gas and liquid chromatography, blood analyzers, distributed data acquisition in factory automation and power generating equipment, and in automatic test equipment.

The DAS1157/DAS1158/DAS1159 make use of Analog Devices' proprietary CMOS technology to achieve low power operation, while utilizing the latest integrated circuit and thin-film components to achieve the highest level of performance and reliability.

As shown in Figure 1, each device contains a precision sample/hold amplifier, high accuracy 14-/15-/16-bit analog-to-digital converter, precision reference, CMOS tri-state output buffers (for direct 8-bit or 16-bit bus interface), user accessible gain and offset adjust potentiometers, and power supply bypass capacitors, all in a compact low profile 2″×4″×0.375″ metal case package. No additional components are required for operation.

OUTLINE DIMENSIONS

Dimensions shown in inches and (mm).

ASSEMBLY INSTRUCTIONS

CAUTION: This module is not an embedded assembly and is not hermetically sealed. Do not subject to a solvent or water-wash process that would allow direct contact with free liquids or vapors. Entrapment of contaminants may occur, causing performance degradation and permanent damage. Install after any clean/wash process and then only spot clean by hand.

NOTES

*Specifications same as DAS1157

**Specifications same as DAS1158

[1]Measured in hold mode, input 20V pk-pk @ 10kHz.

[2]Worst-case summation of S/H and A/D nonlinearity errors.

[3]FSR means Full Scale Range.

[4]Differential Nonlinearity in the 0 to +5V input range is specified as ±0.003% typical for the DAS1157, DAS1158 and DAS1159.

[5]When connecting the Trigger and the S/H control terminals together, the pulse width must be long enough for the S/H amplifier to acquire the input signal to the required accuracy (5µs min). If the A/D converter only is used, the Trigger pulse width should be 1µs min (see Figure 3).

[6]Low Byte Enable pin connections are Bits 8 through 15; High Byte Enable pin connections are $\overline{\text{MSB}}$, MSB or Bit 16 and Bits 2 through 7.

[7]DAS1159 unipolar coding is provided in a modified binary format (MSB complement) while bipolar coding is two's complement only. The MSB must be inverted for binary and offset binary codes.

[8]When the S/H section is required, $-V_S$ must be at least 5 volts more negative than the most negative analog input voltage (example: V_S = ±12V dc, therefore, maximum analog input is +10 and −7V).

[9]Recommended Power Supply: Analog Devices Model 923.

Specifications subject to change without notice.

OPERATION

For operation, the only connections necessary to the DAS1157/DAS1158/DAS1159 are the ±15V and +5V power supplies, analog input signal, trigger pulse, and the HI-ENABLE/LO-ENABLE tri-state controls. Analog input and digital output programming are user selectable via external jumper connections.

Input voltage ranges are selectable via user pin programming: 0 to +5V, 0 to +10V, ±5V and ±10V. Unipolar coding is provided in true binary format with bipolar coding displayed in offset binary and two's complement (DAS1157 and DAS1158). DAS1159 unipolar coding is provided in a modified binary format (MSB complement) while bipolar coding is two's complement only.

ANALOG INPUT SECTION

The analog input can be applied to just the A/D converter or to the internal sample/hold amplifier ahead of the A/D converter. When using just the A/D converter, apply the analog input per the voltage range pin programming shown in Table I. When using the sample/hold amplifier in conjunction with A/D converter, apply the analog input to the S/H INPUT terminal and connect the S/H OUTPUT terminal to the appropriate A/D converter analog input.

Analog Voltage Input Range	Connect V_{IN} or S/H Out To	Connect Analog Common To	Connect Ref Out To
0 to +5V	ANA IN 1, ANA IN 2, ANA IN 3	Ground	NC*
0 to +10V	ANA IN 2 ANA IN 3	Ground ANA IN 1	NC*
±5V	ANA IN 1	Ground, ANA IN 3	ANA IN 2
±10V	ANA IN 3	Ground, ANA IN 1	ANA IN 2

*No Connection

Table I. Analog Input Pin Programming

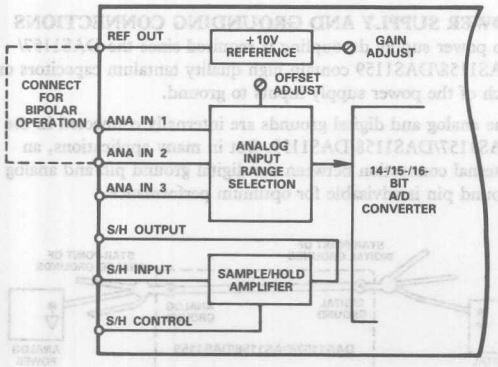

Figure 2. Analog Input Block Diagram

Errors due to source loading are eliminated since the sample/hold amplifier is a high-impedance unity-gain amplifier. High feedthrough rejection is provided for either single-channel or multichannel applications. Feedthrough rejection can be optimized, in multichannel applications, by changing channels at the rising or falling edge of the S/H control pulse.

TIMING DIAGRAM

The timing diagram for the DAS1157/DAS1158/DAS1159 is illustrated in Figure 3. This figure also includes the sample/hold amplifier acquisition time.

If the sample/hold amplifier is required, the TRIGGER input and S/H CONTROL terminal can be tied together providing only one conversion control signal. When the trigger pulse goes high, it places the sample/hold amplifier in the sample mode allowing it to acquire the present input signal. The trigger pulse must remain high for a minimum of 5μs to insure accuracy. If the sample/hold amplifier is not used, the trigger pulse needs to be 1μs (minimum) in length to satisfy the A/D converter trigger requirements. At the falling edge of the trigger pulse, the sample/hold amplifier is placed in the hold mode, all internal logic is reset and the A/D conversion begins. The conversion process can be retriggered at any time, including during conversion.

With this negative edge of the trigger pulse, the MSB is set high with the remaining digital outputs set to logic low state, and the end of conversion is set high and remains high through the full conversion cycle. During conversion each bit, starting with the MSB, is sequentially switched high at the rising edge of the internal clock. The DAC output is then compared to the analog input and the bit decision is made. Each comparison lasts one clock cycle with the complete 14-/15-/16-bit conversion taking 50μs maximum. At this time, the end of conversion line goes low signifying that the conversion is complete. For microprocessor bus applications, the digital output can now be applied to the data bus by enabling the tri-state buffers. For maximum data throughput, the digital output data should be read while the sample/hold amplifier is acquiring the new analog input signal.

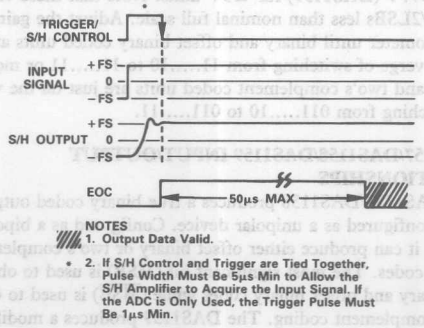

Figure 3. DAS1157/DAS1158/DAS1159 Timing Diagram

7

The DAS1157/DAS1158/DAS1159 contain internal gain and offset adjustment potentiometers. Each potentiometer has ample adjustment range so that gain and offset errors can be trimmed to zero.

Offset calibration is not affected by changes in gain calibration, and should be performed prior to gain calibration. Proper gain and offset calibration requires great care and the use of extremely sensitive and accurate reference instruments. The voltage standard used as a signal source must be very stable and be capable of being set to within ±1/10LSB of the desired value at any point within its range.

OFFSET CALIBRATION

For a 0 to +10V unipolar range, set the input voltage precisely to +305μV for the DAS1157, +153μV for the DAS1158 and +76μV for the DAS1159. For a 0 to +5V unipolar range, set the input to +153μV for the DAS1157, +76μV for the DAS1158 and +38μV for the DAS1159. Then adjust the zero potentiometer until the converter is just on the verge of switching from 000.....000 to 000.....001 (DAS1157/DAS1158) or from 100.....000 to 100.....001 (DAS1159).

For the ±5V bipolar range, set the input voltage precisely to +305μV for the DAS1157, +153μV for the DAS1158 and +76μV for the DAS1159. For a ±10V bipolar range, set the input voltage precisely to +610μV for the DAS1157, +305μV for the DAS1158 and +153μV for the DAS1159. Adjust the zero potentiometer until the offset binary coded units are just on the verge of switching from 000.....000 to 000.....001 and the two's complement coded units are just on the verge of switching from 100.....000 to 100.....001.

GAIN CALIBRATION

Set the input voltage precisely to +9.99909V (DAS1157)/ +9.99954V (DAS1158)/+9.99977V (DAS1159) for the 0 to +10V units, +4.99954V (DAS1157)/+4.99977V (DAS1158)/ +4.99989V (DAS1159) for 0 to +5V units, +9.99817V (DAS1157)/+9.99909V (DAS1158)/+9.99954V (DAS1159) for ±10V units, or +4.99909V (DAS1157)/+4.99954V (DAS1158)/ +4.99977V (DAS1159) for ±5V units. Note that these values are 1 1/2LSBs less than nominal full scale. Adjust the gain potentiometer until binary and offset binary coded units are just on the verge of switching from 11.....10 to 11.....11 or modified binary and two's complement coded units are just on the verge of switching from 011.....10 to 011.....11.

DAS1157/DAS1158/DAS1159 INPUT/OUTPUT RELATIONSHIPS

The DAS1157/DAS1158 produces a true binary coded output when configured as a unipolar device. Configured as a bipolar device, it can produce either offset binary or two's complement output codes. The most significant bit (MSB) is used to obtain the binary and offset binary codes while ($\overline{\text{MSB}}$) is used to obtain two's complement coding. The DAS1159 produces a modified binary coded output when configured as a unipolar device. Configured as a bipolar device it can only produce two's complement output codes. The DAS1159 uses $\overline{\text{MSB}}$ to obtain the modified binary and two's complement output codes; the DAS1159 does not have an MSB output. Table II shows the DAS1157/ DAS1158/DAS1159 unipolar analog input/digital output relationships. Table III shows the DAS1157/DAS1158/DAS1159 bipolar analog input/digital output relationships.

Unipolar Input Voltages

TRI-STATE DIGITAL OUTPUT

The ADC digital outputs are provided in parallel format to the output tri-state buffers. The output information can be applied to a data bus in either a one-byte or a two-byte format by using the HIGH BYTE ENABLE and LOW BYTE ENABLE terminals. If the tri-state feature is not required, normal digital outputs can be obtained by connecting the enable pins to ground.

POWER SUPPLY AND GROUNDING CONNECTIONS

No power supply decoupling is required since the DAS1157/ DAS1158/DAS1159 contain high quality tantalum capacitors on each of the power supply inputs to ground.

The analog and digital grounds are internally connected in the DAS1157/DAS1158/DAS1159. But in many applications, an external connection between the digital ground pin and analog ground pin is advisable for optimum performance.

Orientation
Analog I/O Ports

Analog I/O Port products represent one of the highest levels of integration and functionality available in an IC package. These devices usually consist of the following functional blocks:

- single or multiple channel ADC
- one or more voltage output DACs with varying resolution
- sample-and-hold amplifiers
- one or more voltage references for both the DACs and ADC
- analog and/or digital filters
- associated control logic for easy μP interfacing.

This high level of integration on a chip has several distinct advantages over a multipackage solution. The ability to perform several functions on one chip lowers a systems chip count, thereby decreasing a system's real estate requirements while increasing its reliability. These devices, consisting of the various functional blocks, are fully specified, thus allowing for more predictable performance characteristics over the full operating range. The inherent cost savings due to a lower chip count as well as to lower R&D expenditures make Analog I/O Port devices an attractive solution for many data acquisition and distribution applications.

Our product portfolio for these devices can be subdivided into the following three subcategories: General Purpose, Disk Drive/Servo, and Communications. Some Analog I/O Ports are intended for specific industry applications but should not be considered to be limited to only those applications. General Purpose I/O Ports have a wide range of applications which include:

- digital signal processing
- speech recognition and synthesis
- spectrum analysis
- high speed modems
- servo control
- infinite sample and hold
- analog delay line
- peak detection.

These General Purpose I/O Ports are fully specified for dynamic parameters such as signal-to-noise ratio and harmonic distortion as well as traditional dc specifications.

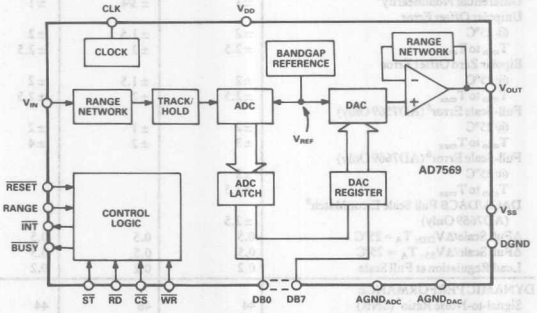
Our Disk Drive/Servo category contains products which span the complete range of disk diameters and capabilities. Products such as the AD7773 and AD7775 contain all the circuitry to implement the demodulation and signal conversion in embedded servo systems. Both devices consist of a differential amplifier front end, a rectifier/integrator, a 10-bit sampling ADC and an 8- and 10-bit DAC. The AD7775 uses a multiplexed address/data bus with an ALE input latch to latch the address while the AD7773 uses a 10-bit data port with separate address pins.

The Communication I/O Port products integrate much of the functional blocks required in various communications applications onto a single chip. The AD28msp01 and the AD28msp02 are linear codecs that provide a complete front end for high performance modem and voiceband DSP applications, while the AD7001/02/05 are three products designed for the Pan-American (GSM) and American Digital Cellular Telephone systems.

DEFINITION OF SPECIFICATIONS

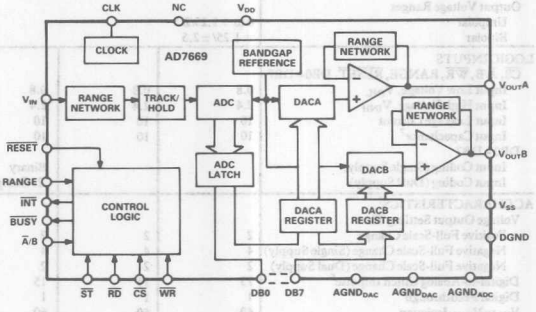
The specifications pertaining to these Analog I/O Port products are similar to those used in evaluating ADCs and DACs.

ANALOG DEVICES



LC²MOS Complete, 8-Bit Analog I/O System

AD7569/AD7669



FEATURES

2μs ADC with Track/Hold
1μs DAC with Output Amplifier
AD7569, Single DAC Output
AD7669, Dual DAC Output
On-Chip Bandgap Reference
Fast Bus Interface
Single or Dual 5V Supplies

FUNCTIONAL BLOCK DIAGRAM

FUNCTIONAL BLOCK DIAGRAM

GENERAL DESCRIPTION

The AD7569/AD7669 is a complete, 8-bit, analog I/O system on a single monolithic chip. The AD7569 contains a high speed successive approximation ADC with 2μs conversion time, a track/hold with 200kHz bandwidth, a DAC and output buffer amplifier with 1μs settling time. A temperature-compensated 1.25V bandgap reference provides a precision reference voltage for the ADC and the DAC. The AD7669 is similar but contains two DACs with output buffer amplifiers.

A choice of analog input/output ranges is available. Using a supply voltage of +5V, input and output ranges of zero to 1.25V and zero to 2.5 volts may be programmed using the RANGE input pin. Using a ±5V supply, bipolar ranges of ±1.25V or ±2.5V may be programmed.

Digital interfacing is via an 8-bit I/O port and standard microprocessor control lines. Bus interface timing is extremely fast, allowing easy connection to all popular 8-bit microprocessors. A separate start convert line controls the track/hold and ADC to give precise control of the sampling period.

The AD7569/AD7669 is fabricated in Linear-Compatible CMOS (LC²MOS), an advanced, mixed technology process combining precision bipolar circuits with low power CMOS logic. The AD7569 is packaged in a 24-pin, 0.3″ wide "skinny" DIP, a 24-terminal SOIC and 28-terminal PLCC and LCCC packages. The AD7669 is available in a 28-pin, 0.6″ plastic DIP, 28-terminal SOIC, and 28-terminal PLCC package.

PRODUCT HIGHLIGHTS

1. Complete Analog I/O on a Single Chip.
   The AD7569/AD7669 provides everything necessary to interface a microprocessor to the analog world. No external components or user trims are required, and the overall accuracy of the system is tightly specified, eliminating the need to calculate error budgets from individual component specifications.
2. Dynamic Specifications for DSP Users.
   In addition to the traditional ADC and DAC specifications the AD7569/AD7669 is specified for AC parameters, including signal-to-noise ratio, distortion and input bandwidth.
3. Fast Microprocessor Interface.
   The AD7569/AD7669 has bus interface timing compatible with all modern microprocessors, with bus access and relinquish times less than 75ns and Write pulse width less than 80ns.

NOTES

[1]Specifications apply to both DACs in the AD7669. V_{OUT} applies to both V_{OUT}A and V_{OUT}B of the AD7669.

[2]Except where noted, specifications apply for all output ranges including bipolar ranges with dual supply operation.

[3]Temperature ranges are as follows: J, K versions; 0 to +70°C
A, B versions; −25°C to +85°C
S, T versions; −55°C to +125°C

[4]1LSB = 4.88mV for 0 to +1.25V output range, 9.76mV for 0 to +2.5V and ±1.25V ranges and 19.5mV for ±2.5V range.

[5]See Terminology.

[6]Includes internal voltage reference error and is calculated after offset error has been adjusted out. Ideal unipolar full-scale voltage is (FS – 1LSB); ideal bipolar positive full-scale voltage is (FS/2 – 1LSB) and ideal bipolar negative full-scale voltage is −FS/2.

[7]Sample tested at 25°C to ensure compliance.

Specifications subject to change without notice.

ADC SPECIFICATIONS

(V_{DD} = +5V ±5%; V_{SS}[1] = RANGE = $AGND_{DAC}$ = $AGND_{ADC}$ = DGND = 0V; f_{CLK} = 5MHz external unless otherwise stated. All specifications T_{min} to T_{max} unless otherwise stated.) Specifications apply to Mode 1 interface.

NOTES

[1]Except where noted, specifications apply for all ranges including bipolar ranges with dual supply operation.

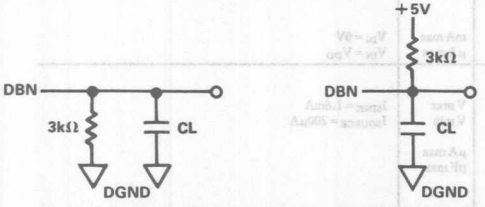
[2]Temperature ranges are as follows: J, K versions; 0 to +70°C
A, B versions; −25°C to +85°C
S, T versions; −55°C to +125°C

[3]1LSB = 4.88mV for 0 to +1.25V range, 9.76mV for 0 to +2.5V and ±1.25V ranges and 19.5mV for ±2.5V range.

[4]See Terminology.

[5]Includes internal voltage reference error and is calculated after offset error has been adjusted out. Ideal unipolar last code transition occurs at (FS – 3/2LSB); Ideal bipolar last code transition occurs at (FS/2 – 3/2LSB).

[6]Exact frequencies are 101kHz and 384kHz to avoid harmonics coinciding with sampling frequency.



[7]Rising edge of $\overline{BUSY}$ to falling edge of $\overline{ST}$. The time given refers to the acquisition time which gives a 3dB degradation in SNR from the tested figure.

[8]Sample tested at 25°C to ensure compliance.

Specifications subject to change without notice.

t_{17}[2]	60	75	90	ns max	Data Valid Time after $\overline{BUSY}$; $C_L = 20pF$
	90	115	135	ns max	Data Valid Time after $\overline{BUSY}$; $C_L = 100pF$

NOTES
[1]Sample tested at +25°C to ensure compliance. All input control signals are specified with $t_R = t_F = 5ns$ (10% to 90% of +5V) and timed from a voltage level of 1.6V.
[2]t_{13} and t_{17} are measured with the load circuits of Figure 1 and defined as the time required for an output to cross either 0.8V or 2.4V.
[3]t_{14} is defined as the time required for the data line to change 0.5V when loaded with the circuit of Figure 2.
Specifications subject to change without notice.

ABSOLUTE MAXIMUM RATINGS

V_{DD} to $AGND_{DAC}$ or $AGND_{ADC}$ . . . . . −0.3V, +7V
V_{DD} to DGND . . . . . −0.3V, +7V
V_{DD} to V_{SS} . . . . . −0.3V, +14V
$AGND_{DAC}$ or $AGND_{ADC}$ to DGND . . −0.3V, V_{DD} +0.3V
$AGND_{DAC}$ to $AGND_{ADC}$ . . . . . ±5V
Logic Voltage to DGND . . . . . −0.3V, V_{DD} +0.3V
CLK Input Voltage to DGND . . . . −0.3V, V_{DD} +0.3V
V_{OUT} (V_{OUT}A, V_{OUT}B) to
$AGND^1_{DAC}$ . . . . . V_{SS} −0.3V, V_{DD}+0.3V
V_{IN} to $AGND_{ADC}$ . . . . . V_{SS} −0.3V, V_{DD} +0.3V

NOTE
[1]Output may be shorted to any voltage in the range V_{SS} to V_{DD} provided that the power dissipation of the package is not exceeded. Typical short circuit current for a short to AGND or V_{SS} is 50mA.

Power Dissipation (Any Package) to +75°C 450mW
Derates above 75°C by . . . . . 6mW/°C
Operating Temperature Range
Commercial (J, K) . . . . . 0 to +70°C
Industrial (A, B) . . . . . −25°C to +85°C
Extended (S, T) . . . . . −55°C to +125°C
Storage Temperature Range . . . . . −65°C to +150°C
Lead Temperature (Soldering, 10 Secs) . . . . . +300°C

*Stress above those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. This is a stress rating only and functional operation of the device at these or any other condition above those indicated in the operational sections of this specification is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

CAUTION

ESD (electrostatic discharge) sensitive device. The digital control inputs are diode protected; however, permanent damage may occur on unconnected devices subject to high energy electrostatic fields. Unused devices must be stored in conductive foam or shunts. The protective foam should be discharged to the destination socket before devices are removed.

NOTE:
The term DAC (Digital-to-Analog Converter) throughout the data sheet applies equally to the dual DACs in the AD7669 as well as to the single DAC of the AD7569 unless otherwise stated. It follows that the term V_{OUT} applies to both $V_{OUT}A$ and $V_{OUT}B$ of the AD7669 also.

TERMINOLOGY

Total Unadjusted Error
Total unadjusted error is a comprehensive specification which includes internal voltage reference error, relative accuracy, gain and offset errors.

Relative Accuracy (DAC)
Relative Accuracy or endpoint nonlinearity is a measure of the maximum deviation from a straight line passing through the endpoints of the DAC transfer function. It is measured after allowing for offset and gain errors. For the bipolar output ranges the endpoints of the DAC transfer function are defined as those voltages which correspond to negative full-scale and positive full-scale codes. For the unipolar output ranges the endpoints are code 1 and code 255. Code 1 is chosen because the amplifier is now working in single supply and in cases where the true offset of the amplifier is negative it cannot be seen at code 0. If the relative accuracy was calculated between code 0 and code 255 the "negative offset" would appear as a linearity error. If the offset is negative and less than 1LSB, it will appear at code 1, and hence the true linearity of the converter is seen between code 1 and code 255.

Relative Accuracy (ADC)
Relative Accuracy is the deviation of the ADC's actual code transition points from a straight line drawn between the endpoints of the ADC transfer function. For the bipolar input ranges these points are the measured negative full-scale transition point and the measured positive full-scale transition point. For the unipolar ranges the straight line is drawn between the measured first LSB transition point and the measured full-scale transition point.

Differential Nonlinearity
Differential Nonlinearity is the difference between the measured change and an ideal 1LSB change between any two adjacent codes. A specified differential nonlinearity of ±1LSB max ensures monotonicity (DAC) or no missed codes (ADC). A differential nonlinearity of ±3/4LSB max ensures that the minimum step size (DAC) or code width (ADC) is 1/4LSB and the maximum step size or code width is 3/4LSB.

Digital-to-Analog Glitch Impluse
Digital-to-Analog Glitch Impulse is the impulse injected into the analog output when the digital inputs change state with the DAC selected. It is normally specified as the area of the glitch in nVsecs and is measured when the digital input code is changed by 1LSB at the major carry transition.

Digital Feedthrough
Digital Feedthrough is also a measure of the impulse injected to the analog output from the digital inputs but is measured when the DAC is not selected. It is essentially feedthrough across the die and package. It is also a measure of the glitch impulse transferred to the analog output when data is read from the internal ADC. It is specified in nVsecs and is measured with $\overline{WR}$ high and a digital code change from all 0s to all 1s.

DAC-to-DAC Crosstalk (AD7669 Only)
The glitch energy transferred to the output of one DAC due to an update at the output of the second DAC. The figure given is the worst case and is expressed in nV secs. It is measured with an update voltage of full scale.

DAC-to-DAC Isolation (AD7669 Only)
DAC-to-DAC Isolation is the proportion of a digitized sine wave from the output of one DAC which appears at the output of the second DAC (loaded with all 1s). The figure given is the worst case for the second DAC output and is expressed as a ratio in dBs. It is measured with a digitized sine wave ($f_{SAMPLING}$ = 100kHz) of 20kHz at 2.5V pk-pk.

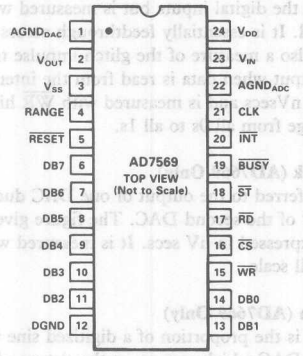
Signal-to-Noise Ratio
Signal-to-Noise Ratio (SNR) is the measured signal to noise at the output of the converter. The signal is the rms magnitude of the fundamental. Noise is the rms sum of all the nonfundamental signals (excluding dc) up to half the sampling frequency. SNR is dependent on the number of quantization levels used in the digitization process; the more levels, the smaller the quantization noise. The theoretical SNR for a sine wave is given by

$$SNR = (6.02N + 1.76)\ dB$$

where N is the number of bits. Thus for an ideal 8-bit converter, SNR = 50dB.

Harmonic Distortion
Harmonic Distortion is the ratio of the rms sum of harmonics to the fundamental. For the AD7569/AD7669, Total Harmonic Distortion (THD) is defined as

$$20 \log \frac{\sqrt{V_2^2 + V_3^2 + V_4^2 + V_5^2 + V_6^2}}{V_1}$$



where V_1 is the rms amplitude of the fundamental and V_2, V_3, V_4, V_5 and V_6 are the rms amplitudes of the individual harmonics.

Intermodulation Distortion
With inputs consisting of sine waves at two frequencies, fa and fb, any active device with nonlinearities will create distortion products, of order (m+n), at sum and difference frequencies of mfa ± nfb, where m,n = 0, 1, 2, 3,.... . Intermodulation terms are those for which m or n is not equal to zero. For example, the second order terms include (fa + fb) and (fa − fb) and the third order terms include (2fa + fb), (2fa − fb), (fa + 2fb) and (fa − 2fb).

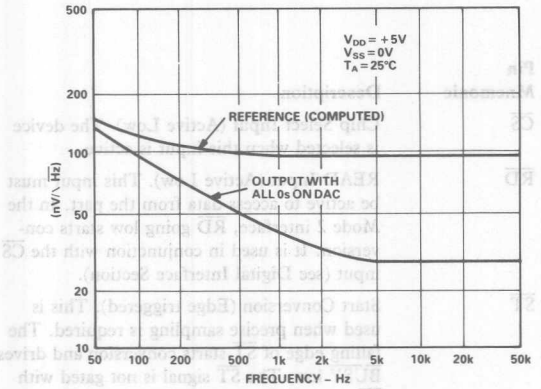
PIN FUNCTION DESCRIPTION

(Applies to the AD7569 and AD7669 unless otherwise stated.)

Pin Mnemonic	Description
$AGND_{DAC}$	Analog Ground for the DAC(s). Separate ground return paths are provided for the DAC(s) and ADC to minimize crosstalk.
V_{OUT} ($V_{OUT}A$, $V_{OUT}B$)	Output Voltage. V_{OUT} is the buffered output voltage from the AD7569 DAC. $V_{OUT}A$ and $V_{OUT}B$ are the buffered DAC output voltages from the AD7669. Four different output voltage ranges can be achieved (see Table I).
V_{SS}	Negative Supply Voltage ($-5V$ for dual supply or 0V for single supply). This pin is also used with the RANGE pin to select the different input/output ranges and changes the data format from binary ($V_{SS} = 0V$) to 2s complement ($V_{SS} = -5V$) (see Table I).
RANGE	Range Selection Input. This is used with the V_{SS} input to select the different ranges as per Table I. The range selected applies to both the analog input voltage of the ADC and the output voltage from the DAC(s).
$\overline{RESET}$	Reset Input (Active Low). This is an asynchronous system reset which clears the DAC register(s) to all 0s and clears the $\overline{INT}$ line of the ADC (i.e., makes the ADC ready for new conversion). In unipolar operation this input sets the output voltage to 0V; in bipolar operation it sets the output to negative full scale.
DB7	Data Bit 7. Most Significant Bit (MSB).
DB6–DB2	Data Bit 6 to Data Bit 2.
DGND	Digital Ground.
DB1	Data Bit 1.
DB0	Data Bit 0. Least Significant Bit (LSB).
$\overline{WR}$	Write Input (Edge triggered). This is used in conjunction with $\overline{CS}$ to write data into the AD7569 DAC register. It is used in conjunction with $\overline{CS}$ and A/B to write data into the selected DAC register of the AD7669. Data is transferred on the rising edge of $\overline{WR}$.



Pin Mnemonic	Description
$\overline{CS}$	Chip Select Input (Active Low). The device is selected when this input is active.
$\overline{RD}$	READ Input (Active Low). This input must be active to access data from the part. In the Mode 2 interface, $\overline{RD}$ going low starts conversion. It is used in conjunction with the $\overline{CS}$ input (see Digital Interface Section).
$\overline{ST}$	Start Conversion (Edge triggered). This is used when precise sampling is required. The falling edge of $\overline{ST}$ starts conversion and drives $\overline{BUSY}$ low. The $\overline{ST}$ signal is not gated with $\overline{CS}$.
$\overline{BUSY}$	BUSY Status Output (Active Low). When this pin is active the ADC is performing a conversion. The input signal is held prior to the falling edge of $\overline{BUSY}$ (see Digital Interface Section).
$\overline{INT}$	INTERRUPT Output (Active Low). $\overline{INT}$ going low indicates that the conversion is complete. $\overline{INT}$ goes high on the rising edge of $\overline{CS}$ or $\overline{RD}$ and is also set high by a low pulse on $\overline{RESET}$ (see Digital Interface Section).
A/B (AD7669 Only)	DAC Select Input. This input selects which DAC register data is written to under control of $\overline{CS}$ and $\overline{WR}$. With this input low data is written to the DACA register; with this input high data is written to the DACB register.
CLK	A TTL compatible clock signal may be used to determine the ADC conversion time. Internal clock operation is achieved by connecting a resistor and capacitor to ground.
$AGND_{ADC}$	Analog Ground for the ADC.
V_{IN}	Analog Input. Various input ranges can be selected (see Table I).
V_{DD}	Positive Supply Voltage ($+5V$).

Range	V_{SS}	Input/Output Voltage Range	DB0–DB7 Data Format
0	0V	0 to +1.25V	Binary
1	0V	0 to +2.5V	Binary
0	−5V	±1.25V	2s Complement
1	−5V	±2.5V	2s Complement

CIRCUIT DESCRIPTION

D/A SECTION

The AD7569 contains an 8-bit, voltage-mode, D/A converter which uses eight equally weighted current sources switched into an R-2R ladder network to give a direct but unbuffered 0 to +1.25V output range. The AD7669 is similar but contains two D/A converters. The current sources are fabricated using PNP transistors. These transistors allow current sources which are driven from positive voltage logic and give a zero-based output range. The output voltage from the voltage switching R-2R ladder network has the same positive polarity as the reference and therefore the D/A converter can be operated from a single power supply rail.

The PNP current sources are generated using the on-chip bandgap reference and a control amplifier. The current sources are switched to either the ladder or $AGND_{DAC}$ by high speed p-channel switches. These high-speed switches ensure a fast settling time for the output voltage of the DAC. The R-2R ladder network of the DAC consists of highly stable, thin-film resistors. A simplified circuit diagram for the D/A converter section is shown in Figure 3. An identical D/A converter is used as part of the A/D converter which is discussed later.

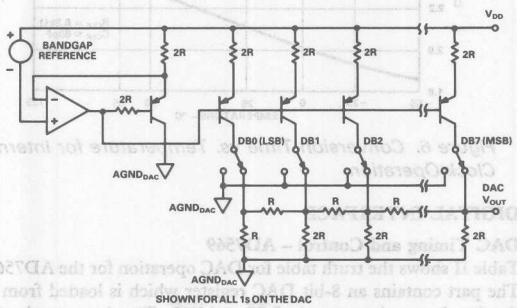

Figure 3. DAC Simplified Circuit Diagram

OP AMP SECTION

The output from the D/A converter is buffered by a high speed, noninverting op amp. This op amp is capable of developing ±2.5V across a 2kΩ and 100pF load to $AGND_{DAC}$. The amplifier can be operated from a single +5V supply to give two unipolar output ranges or from dual supplies (±5V) to allow two bipolar output ranges.

The feedback path of the amplifier contains a gain/offset network which provides four voltage ranges at the output of the op amp. The output voltage range is determined by the RANGE and V_{SS} inputs. (See Table I in the Pin Function Description section.) The four output ranges possible are: 0 to +1.25V, 0 to +2.5V, ±1.25V and ±2.5V. It should be noted that whatever range is selected for the output amplifier also applies to the input voltage range of the A/D converter.

The output amplifier settles to within 1/2LSB of its final value in typically less than 500ns. Operating the part from single or dual supplies has no effect on the positive-going settling time. However, the negative-going output settling time to voltages near 0V in single supply will be slightly longer than the settling time to negative full scale for dual supply operation. Additionally, to ensure that the output voltage can go to 0V in single supply, a transistor on the output acts as a passive pull-down with output voltages near 0V with V_{SS} = 0V. This means that the sink capability of the amplifier is reduced as the output voltage nears 0V in single supply. In dual supply operation the full sink capability of 1.25mA is maintained over the entire output voltage range.

For all other parameters the single and dual supply performances of the amplifier are essentially identical. The output noise from the amplifier with full scale on the DAC is 200μV peak-to-peak. The spot noise at 1kHz is 35nV/$\sqrt{Hz}$ with all 0s on the DAC. A noise spectral density versus frequency plot for the amplifier is shown in the typical performance graphs.

VOLTAGE REFERENCE

The AD7569/AD7669 contains an on-chip bandgap reference which provides a low noise, temperature compensated reference voltage for both the DAC and the ADC. The reference is trimmed for both absolute accuracy and temperature coefficient. The bandgap reference is generated with respect to V_{DD}. It is buffered by a separate control amplifier for both the DAC and the ADC reference. This can be seen in the DAC ladder network configuration in Figure 3.

DIGITAL SECTION

The data pins on the AD7569/AD7669 provide a connection between the external bus and both the DAC data inputs and ADC data outputs. The threshold levels of all digital inputs and outputs are compatible with either TTL or 5V CMOS levels. Internal input protection of all digital pins is achieved by on-chip distributed diodes.

The data format is straight binary when the part is used in single supply (V_{SS} = 0V). However, when a V_{SS} of −5V is applied, the data format becomes 2s complement. This data format applies to the digital inputs of the DAC and the digital outputs of the ADC.

ADC SECTION

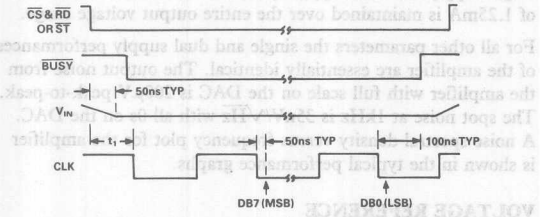
The analog-to-digital converter on the AD7569/AD7669 uses the successive approximation technique to achieve a fast conversion time of 2μs and provide an 8-bit parallel digital output. The reference for the ADC is provided by the on-chip bandgap reference.

Conversion start is controlled by $\overline{ST}$ or by $\overline{CS}$ and $\overline{RD}$. Once a conversion has been started another conversion start should not be attempted until the conversion in progress is completed. Exercising the $\overline{RESET}$ input does not affect conversion; the $\overline{RESET}$ input resets the $\overline{INT}$ line high which is useful in interrupt-driven systems where a READ has not been performed at the end of the previous conversion. The $\overline{INT}$ line does not have to be cleared at the end of conversion. The ADC will continue to convert correctly but the function of the $\overline{INT}$ line will be affected.

Figure 4 shows the operating waveforms for a conversion cycle. The analog input voltage, V_{IN}, is held 50ns typical after the falling edge of $\overline{ST}$ or ($\overline{CS}$ & $\overline{RD}$). The MSB decision is made approximately 50ns after the second falling edge of the input CLK following a conversion start. If t_1 in Figure 4 is greater than 50ns, then the falling edge of the input CLK will be seen as the first falling clock edge. If t_1 is less than 50ns, the first falling clock edge of the conversion will not occur until one clock cycle later. The succeeding bit decisions are made approximately 50ns after a CLK edge until conversion is complete. At

8

the end of conversion, the SAR contents are transferred to the output latch and the SAR is reset in readiness for a new conversion. A single conversion lasts for 8 input clock cycles.



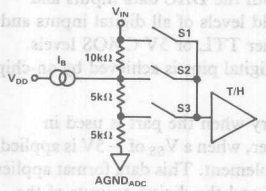


Figure 4. Operating Waveforms Using External Clock

ANALOG INPUT

The analog input of the AD7569/AD7669 feeds into an on-chip track-and-hold amplifier. To accommodate different full-scale ranges, the analog input signal is conditioned by a gain/offset network which conditions all input ranges so that the internal ADC always works with a 0 to +1.25V signal. As a result, the input current on the V_{IN} input varies with the input range selected as shown in Figure 5.

VOLTAGE RANGE	ON SWITCH	I_B
0 TO +1.25V	S1	20μA
0 TO +2.5V	S2	20μA
−1.25V TO +1.25V	S2	140μA
−2.5V TO +2.5V	S3	280μA

Figure 5. Equivalent V_{IN} Circuit

TRACK-AND-HOLD

The track-and-hold (T/H) amplifier on the analog input of the AD7569/AD7669 allows the ADC to accurately convert an input sine wave of 2.5V peak-to-peak amplitude up to a frequency of 200kHz, the Nyquist frequency of the ADC when operated at its maximum throughput rate of 400kHz. This maximum rate of conversion includes conversion time and time between conversions. Because the input bandwidth of the T/H amplifier is much larger than 200kHz, the input signal should be band-limited to avoid converting high-frequency noise components.

The operation of this T/H amplifier is essentially transparent to the user. The T/H amplifier goes from its tracking mode to its hold mode at the start of conversion. This occurs when the ADC receives a conversion start command from either $\overline{ST}$ or $\overline{CS}$ & $\overline{RD}$. At the end of conversion ($\overline{BUSY}$ going high) the T/H reverts back to tracking the input signal.

EXTERNAL CLOCK

The AD7569/AD7669 ADC can be used with its on-chip clock or with an externally applied clock. When using an external clock, the CLK input of the AD7569/AD7669 may be driven directly from 74HC, 4000B series buffers (such as 4049) or from TTL buffers. When conversion is complete, the internal clock is disabled. The external clock can continue to run between conversions without being disabled. The mark/space ratio of the external clock can vary from 70/30 to 30/70.

INTERNAL CLOCK

Clock pulses are generated by the action of an internal current source charging the external capacitor (C_{CLK}) and this external capacitor discharging through the external resistor (R_{CLK}). When a conversion is complete, this internal clock stops operating and the CLK pin goes to the DGND potential. Connections for R_{CLK} and C_{CLK} are shown in the operating diagram of Figure 21. The nominal conversion time versus temperature for the recommended R_{CLK} and C_{CLK} combination is shown in Figure 6. The internal clock provides a convenient clock source for the AD7569/AD7669. Due to process variations, the actual operating frequency for this R_{CLK}/C_{CLK} combination can vary from device to device by up to ±25%.

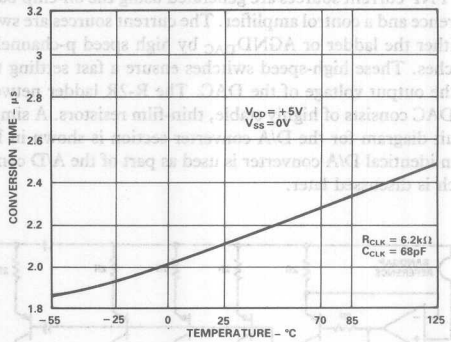

Figure 6. Conversion Time vs. Temperature for Internal Clock Operation

DIGITAL INTERFACE

DAC Timing and Control – AD7569

Table II shows the truth table for DAC operation for the AD7569. The part contains an 8-bit DAC register which is loaded from the data bus under control of $\overline{CS}$ and $\overline{WR}$. The data contained in the DAC register determines the analog output from the DAC. The $\overline{WR}$ input is an edge-triggered input and data is transferred into the DAC register on the rising edge of $\overline{WR}$. Holding $\overline{CS}$ and $\overline{WR}$ low does not make the DAC register transparent.

$\overline{CS}$	$\overline{WR}$	$\overline{RESET}$	DAC Function
H	H	H	DAC Register Unaffected
L	L	H	DAC Register Unaffected
L	↑	H	DAC Register Updated
↑	L	H	DAC Register Updated
X	X	L	DAC Register Loaded with All Zeros

L = Low State H = High State X = Don't Care

Table II. AD7569 DAC Truth Table

The contents of the DAC register are reset to all 0s by an active low pulse on the $\overline{RESET}$ line and for the unipolar output ranges the output remains at 0V after $\overline{RESET}$ returns high. For the bipolar output ranges a low pulse on $\overline{RESET}$ causes the output to go to negative full scale. In unipolar applications the $\overline{RESET}$ line can be used to ensure power-up to 0V on the AD7569 DAC output and is also useful when used as a zero override in system calibration cycles. If the $\overline{RESET}$ input is connected to the system

RESET line, then the DAC output resets to 0V when the entire system is reset. Figure 7 shows the input control logic for the AD7569 DAC and the write cycle timing diagram is shown in Figure 8.

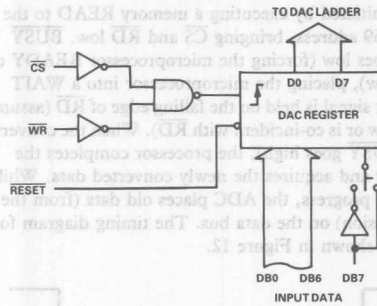

Figure 7. AD7569 DAC Input Control Logic

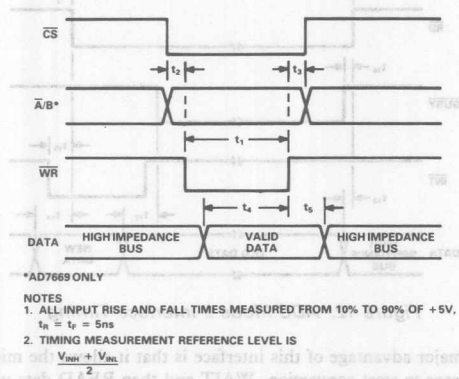

Figure 8. AD7569/AD7669 Write Cycle Timing Diagram

DAC Timing and Control – AD7669

Table III shows the truth table for the dual DAC operation of the AD7669. The part contains two 8-bit DAC registers which are loaded from the data bus under the control of CS, A/B and WR. Address line A/B selects which DAC register the data is loaded to. The data contained in the DAC registers determines the analog output from the respective DACs. The WR input is an edge-triggered input and data is transferred into the selected DAC register on the rising edge of WR. Holding CS and WR low does not make the selected DAC register transparent. The A/B input should not be changed while CS and WR are low.

CS	WR	A/B	RESET	DAC Function
H	H	X	H	DAC Registers Unaffected
L	↑	L	H	DACA Register Updated
↑	L	L	H	DACA Register Updated
L	↑	H	H	DACB Register Updated
↑	L	H	H	DACB Register Updated
X	X	X	L	DAC Registers Loaded with All Zeros

L = Low State H = High State X = Don't Care

Table III. AD7669 DAC Truth Table

The contents of the DAC registers are reset to all 0s by an active low pulse on the RESET line and for the unipolar output ranges the outputs remain at 0V after RESET returns high. For the bipolar output ranges a low pulse on RESET causes the outputs to go to negative full scale. In unipolar applications the RESET line can be used to ensure power-up to 0V on the AD7669 DAC outputs and is also useful when used as a zero override in system calibration cycles. If the RESET input is connected to the system RESET line, then the DAC outputs reset to 0V when the entire system is reset. Figure 9 shows the DAC input control logic for the AD7669, and the write cycle timing diagram is shown in Figure 8.

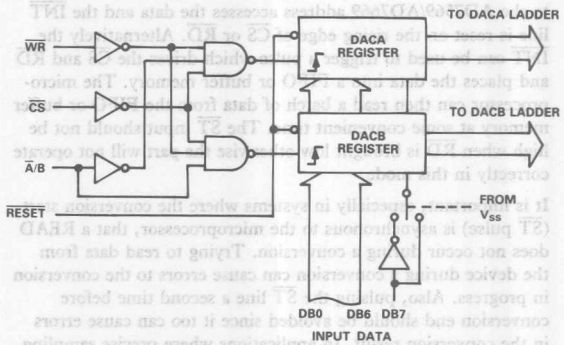

Figure 9. AD7669 DAC Control Logic

ADC Timing and Control

The ADC on the AD7569/AD7669 is capable of two basic operating modes. In the first mode the ST line is used to start conversion and drive the track-and-hold into hold mode. At the end of conversion the track-and-hold returns to its tracking mode. The second mode is achieved by hard-wiring the ST line high. In this case, CS and RD start conversion and the microprocessor is driven into a WAIT state for the duration of conversion by BUSY.

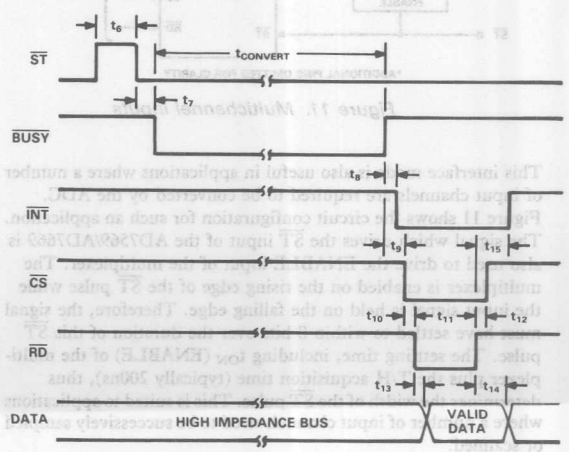

Figure 10. ADC Mode 1 Interface Timing

8

The timing diagram for the first mode is shown in Figure 10. It can be used in digital signal processing and other applications where precise sampling in time is required. In these applications it is important that the signal sampling occurs at exactly equal intervals to minimize errors due to sampling uncertainty or jitter. In these cases the $\overline{ST}$ line is driven by a timer or some precise clock source.

The falling edge of the $\overline{ST}$ pulse starts conversion and drives the AD7569/AD7669 track-and-hold amplifier into its hold mode. $\overline{BUSY}$ stays low for the duration of conversion and returns high at the end of conversion and the track-and hold amplifier reverts to its tracking mode on this rising edge of $\overline{BUSY}$. The $\overline{INT}$ line can be used to interrupt the microprocessor. A READ to the AD7569/AD7669 address accesses the data and the $\overline{INT}$ line is reset on the rising edge of $\overline{CS}$ or $\overline{RD}$. Alternatively the $\overline{INT}$ can be used to trigger a pulse which drives the $\overline{CS}$ and $\overline{RD}$ and places the data into a FIFO or buffer memory. The microprocessor can then read a batch of data from the FIFO or buffer memory at some convenient time. The $\overline{ST}$ input should not be high when $\overline{RD}$ is brought low otherwise the part will not operate correctly in this mode.

It is important, especially in systems where the conversion start ($\overline{ST}$ pulse) is asynchronous to the microprocessor, that a READ does not occur during a conversion. Trying to read data from the device during a conversion can cause errors to the conversion in progress. Also, pulsing the $\overline{ST}$ line a second time before conversion end should be avoided since it too can cause errors in the conversion result. In applications where precise sampling is not critical the $\overline{ST}$ pulse can be generated from a microprocessor $\overline{WR}$ or $\overline{RD}$ line gated with a decoded address (different to AD7569/AD7669 $\overline{CS}$ address).

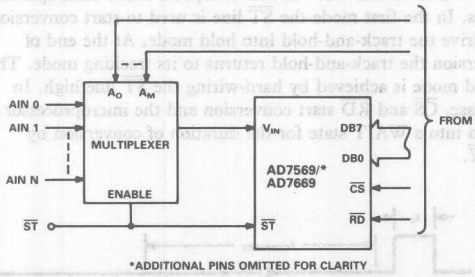

Figure 11. Multichannel Inputs

This interface mode is also useful in applications where a number of input channels are required to be converted by the ADC. Figure 11 shows the circuit configuration for such an application. The signal which drives the $\overline{ST}$ input of the AD7569/AD7669 is also used to drive the ENABLE input of the multiplexer. The multiplexer is enabled on the rising edge of the $\overline{ST}$ pulse while the input signal is held on the falling edge. Therefore, the signal must have settled to within 8 bits over the duration of this $\overline{ST}$ pulse. The settling time, including t_{ON} (ENABLE) of the multiplexer plus the T/H acquisition time (typically 200ns), thus determines the width of the $\overline{ST}$ pulse. This is suited to applications where a number of input channels need to be successively sampled or scanned.

The second interface mode is intended for use with microprocessors which can be forced into a WAIT state for at least 2µs. The $\overline{ST}$ line of the AD7569/AD7669 must be hard-wired high to achieve this mode. The microprocessor starts a conversion and is halted until the result of the conversion is read from the converter. Conversion is initiated by executing a memory READ to the AD7569/AD7669 address, bringing $\overline{CS}$ and $\overline{RD}$ low. $\overline{BUSY}$ subsequently goes low (forcing the microprocessor READY or WAIT input low), placing the microprocessor into a WAIT state. The input signal is held on the falling edge of $\overline{RD}$ (assuming $\overline{CS}$ is already low or is co-incident with $\overline{RD}$). When the conversion is complete ($\overline{BUSY}$ goes high), the processor completes the memory READ and acquires the newly converted data. While conversion is in progress, the ADC places old data (from the previous conversion) on the data bus. The timing diagram for this interface is shown in Figure 12.

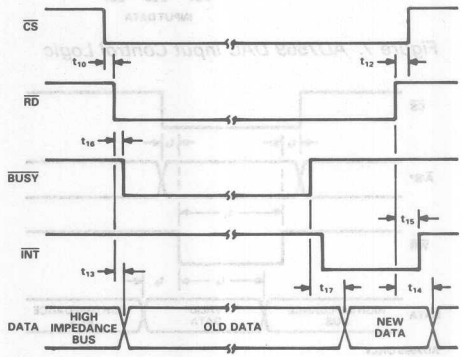

Figure 12. ADC Mode 2 Interface Timing

The major advantage of this interface is that it allows the microprocessor to start conversion, WAIT and then READ data with a single READ instruction. The user does not have to worry about servicing interrupts or ensuring that software delays are long enough to avoid reading during conversion. The fast conversion time of the ADC ensures that for many microprocessors, the processor is not placed in a WAIT state for an excessive amount of time.

DIGITAL SIGNAL PROCESSING APPLICATIONS

In Digital Signal Processing (DSP) application areas like voice recognition, echo cancellation and adaptive filtering, the dynamic characteristics (SNR, Harmonic Distortion, Intermodulation Distortion) of both the ADC and DAC are critical. The AD7569/AD7669 is specified dynamically as well as with standard dc specifications. Because the track/hold amplifier has a wide bandwidth, an anti-aliasing filter should be placed on the V_{IN} input to avoid aliasing of high-frequency noise back into the band of interest.

The dynamic performance of the ADC is evaluated by applying a sine-wave signal of very low distortion to the V_{IN} input which is sampled at a 409.6kHz sampling rate. A Fast Fourier Transform (FFT) plot or Histogram plot is then generated from which SNR, harmonic distortion and dynamic differential nonlinearity data can be obtained. For the DAC, the codes for an ideal sine wave are stored in PROM and loaded down to the DAC. The output spectrum is analyzed, using a spectrum analyzer to evaluate

consisting of pure sine waves at two frequencies is applied to the AD7569/AD7669.

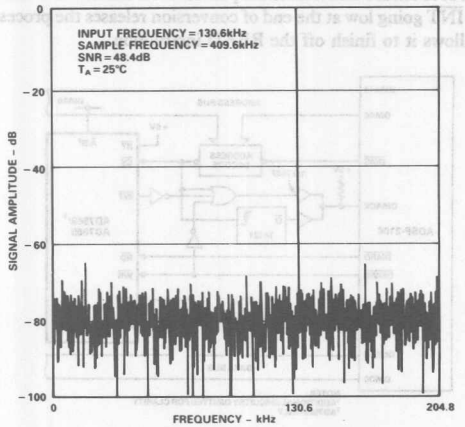

Figure 13. ADC FFT Plot

Figure 13 shows a 2048 point FFT plot of the ADC with an input signal of 130kHz. The SNR is 48.4dB. It can be seen that most of the harmonics are buried in the noise floor. It should be noted that the harmonics are taken into account when calculating the SNR. The relationship between SNR and resolution(N) is expressed by the following equation:

$$SNR = (6.02N + 1.76)dB$$

This is for an ideal part with no differential or integral linearity errors. These errors will cause a degradation in SNR. By working backwards from the above equation, it is possible to get a measure of ADC performance expressed in effective number of bits (N). This effective number of bits is plotted versus frequency in Figure 14. The effective number of bits typically falls between 7.7 and 7.8 corresponding to SNR figures of 48.1 and 48.7dB.

Figure 15 shows a spectrum analyzer plot of the output spectrum from the DAC with an ideal sine-wave table loaded to the data inputs of the DAC. In this case, the SNR is 46dB.

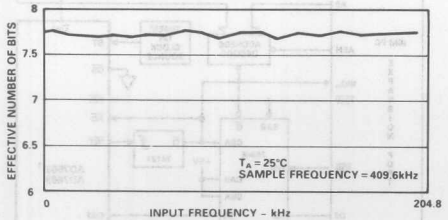

Figure 14. Effective Number of Bits vs. Frequency

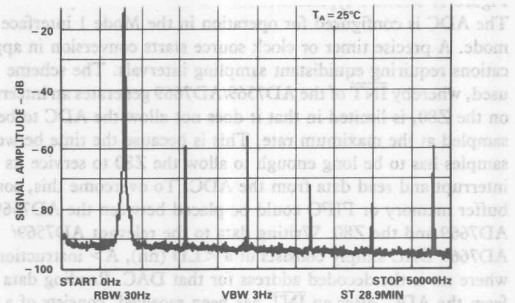

Figure 15. DAC Output Spectrum

HISTOGRAM PLOT

When a sine wave of specified frequency is applied to the V_{IN} input of the AD7569/AD7669 and several thousand samples are taken, it is possible to plot a histogram showing the frequency of occurrence of each of the 256 ADC codes. If a particular step is wider than the ideal 1LSB width, then the code associated with that step will accumulate more counts than for the code for an ideal step. Likewise, a step narrower than ideal width will have fewer counts. Missing codes are easily seen because a missing code means zero counts for a particular code. The absence of large spikes in the plot indicates small differential nonlinearity.

Figure 16 shows a histogram plot for the ADC indicating very small differential nonlinearity and no missing codes for an input frequency of 204kHz. For a sine-wave input, a perfect ADC would produce a cusp probability density function described by the equation

$$p(V) = \frac{1}{\pi (A^2 - V^2)^{1/2}}$$

where A is the peak amplitude of the sine wave and p(V) the probability of occurrence at a voltage V.

The histogram plot of Figure 16 corresponds very well with this cusp shape.

Further typical plots of the performance of the AD7569/AD7669 are shown in the Typical Performance Graphs section of the data sheet.

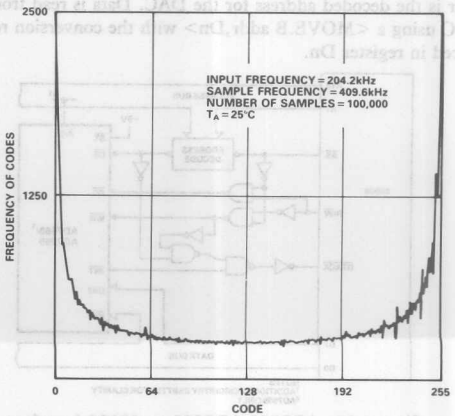

Figure 16. ADC Histogram Plot

8

INTERFACING THE AD7569/AD7669

AD7569/AD7669 – Z80 INTERFACE

Figure 17 shows a typical interface to the Z80 microprocessor. The ADC is configured for operation in the Mode 1 interface mode. A precise timer or clock source starts conversion in applications requiring equidistant sampling intervals. The scheme used, whereby $\overline{INT}$ of the AD7569/AD7669 generates an interrupt on the Z80, is limited in that it does not allow the ADC to be sampled at the maximum rate. This is because the time between samples has to be long enough to allow the Z80 to service its interrupt and read data from the ADC. To overcome this, some buffer memory or FIFO could be placed between the AD7569/AD7669 and the Z80. Writing data to the relevant AD7569/AD7669 DAC simply consists of a <LD (nn), A> instruction where nn is the decoded address for that DAC. Reading data from the ADC, after an $\overline{INT}$ has been received, consists of a <LDA, (nn)> instruction.

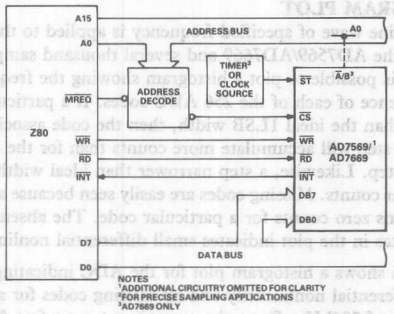

Figure 17. AD7569/AD7669 to Z80 Interface

AD7569/AD7669 – 68008 INTERFACE

A typical interface to the 68008 is shown in Figure 18. In this case the ADC is configured in the Mode 2 interface mode. This means that the one read instruction starts conversion and reads the data. The read cycle is stretched out over the entire conversion period by taking the $\overline{INT}$ line back into the $\overline{DTACK}$ input of the 68008. The additional gates are required so that the 68008 gets a $\overline{DTACK}$ when the processor is writing data to the AD7569/AD7669. In this case there are no wait states introduced into the write cycle. Writing data to the relevant AD7569/AD7669 DAC consists of a <MOVE.B Dn, addr> where Dn is the data register which contains the data to be loaded to that DAC and addr is the decoded address for the DAC. Data is read from the ADC using a <MOVE.B addr,Dn> with the conversion result placed in register Dn.

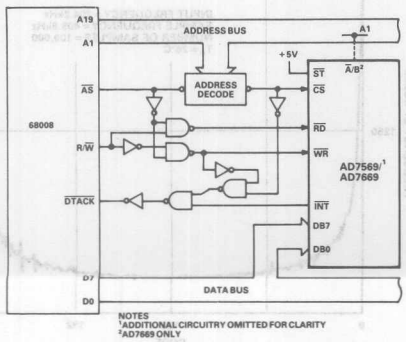

Figure 18. AD7569/AD7669 to 68008 Interface

AD7569/AD7669 – ADSP-2100 INTERFACE

Figure 19 shows a typical interface to the DSP processor, the ADSP-2100. The ADC is in the Mode 2 interface mode which means that the ADSP-2100 is halted during conversion. This is achieved using the decoded address output. This is gated with $\overline{DMWR}$ to ensure that it halts the processor for READ instructions only. $\overline{INT}$ going low at the end of conversion releases the processor and allows it to finish off the READ instruction.

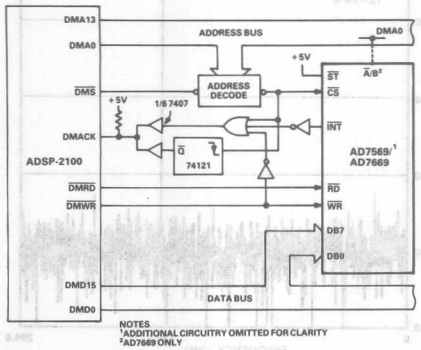

Figure 19. AD7569/AD7669 to ADSP-2100 Interface

Because the instruction cycle of the ADSP-2100 is so fast (125ns cycle) the $\overline{DMWR}$ pulse has to be stretched also for write cycles. This is achieved using the 74121 which generates a pulse which is fed back to DMACK. The duration of this pulse determines how long the ADSP-2100 write cycle is stretched. The buffers which drive the DMACK line must have open-collector outputs. Writing data to the relevant AD7569/AD7669 DAC is achieved using a single instruction, <DM (addr) = MRO> where addr is the decoded address of that DAC and MRO contains the data to be loaded to the DAC register. Data is read from the ADC using a single instruction also, <MRO = DM (addr)>where the conversion result is placed in the MRO data register.

AD7569/AD7669 – IBM PC* INTERFACE

The AD7569/AD7669 is ideal for implementing an analog input/output port for the IBM PC. Figure 20 shows an interface which realizes this function. The ADC is configured in the Mode 1 interface mode and conversions are initiated using a precise clock source for equidistant sampling intervals. At the end of

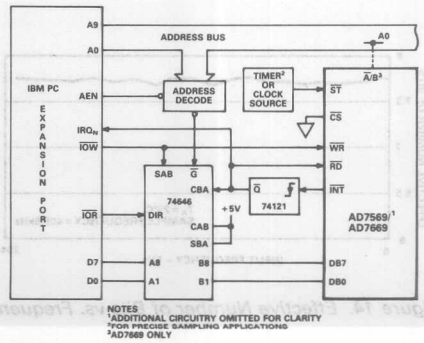

Figure 20. AD7569/AD7669 to IBM PC Interface

conversion the $\overline{INT}$ line goes low, and the 74121 generates a $\overline{RD}$ pulse for the AD7569/AD7669. This $\overline{RD}$ pulse accesses data from the ADC and places the conversion result into a register on the 74646. The rising edge of this pulse generates an interrupt request to the processor. The conversion result is read from the 74646 register by performing an I/0 read to the decoded address of the 74646. Writing data to the relevant AD7569/AD7669 DAC involves an I/0 write to the 74646 which transfers the data to the data inputs of the AD7569/AD7669. Data is latched into the selected DAC register on the rising edge of $\overline{IOW}$.

APPLYING THE AD7569/AD7669 DAC

An internal gain/offset network on the AD7569/AD7669 allows several output voltage ranges. The part can produce unipolar output ranges of 0 to +1.25V or 0 to +2.5V and bipolar output ranges of −1.25V to +1.25V or −2.5V to +2.5V. Connections for these various output ranges are outlined below.

UNIPOLAR (0 to +1.25V) CONFIGURATION

The first of the configurations provides an output voltage range of 0 to +1.25V. This is achieved by tying the V_{SS} and RANGE inputs to $AGND_{DAC}$(=0V). Figure 21 shows the configuration of the AD7569 to achieve this output range. A similar configuration of the AD7669 gives the same output range. The table for output voltage versus the digital code in the DAC register is shown in Table IV.

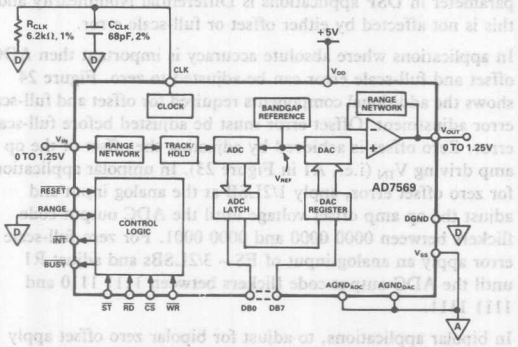

Figure 21. AD7569 Unipolar (0 to +1.25V) Operation

DAC Register Contents MSB	LSB	Analog Output, V_{OUT}
1111	1111	$+V_{REF}\left(\frac{255}{256}\right)$
1000	0001	$+V_{REF}\left(\frac{129}{256}\right)$
1000	0000	$+V_{REF}\left(\frac{128}{256}\right) = +V_{REF}/2$
0111	1111	$+V_{REF}\left(\frac{127}{256}\right)$
0000	0001	$+V_{REF}\left(\frac{1}{256}\right)$
0000	0000	0V

NOTE: 1LSB = $(V_{REF})(2^{-8}) = V_{REF}$ (1/256); V_{REF} = +1.25V Nominal

Table IV. Unipolar (0 to +1.25V) Code Table

UNIPOLAR (0 to +2.5V) CONFIGURATION

The 0 to +2.5V output voltage range is achieved by tying V_{SS} to $AGND_{DAC}$(=0V) and the RANGE input to V_{DD}. The table for output voltage versus digital code is as in Table IV, with $2.V_{REF}$ replacing V_{REF}. Note that for this range

$$1LSB = 2.V_{REF}(2^{-8}) = V_{REF}\frac{1}{128}$$

BIPOLAR (−1.25V to +1.25V) CONFIGURATION

The first of the bipolar configurations is achieved by tying the RANGE input to $AGND_{DAC}$(=0V) and V_{SS} to −5V. The V_{SS} voltage level at which the AD7569/AD7669 changes to bipolar operation is approximately −1V. When the part is configured for bipolar outputs the input coding becomes 2s complement. The table for output voltage versus the digital code in the DAC register is shown in Table V. Note that, as with the unipolar configuration, a digital input code of all 0s produces an output of 0V. It should be noted, however, that a low pulse on the $\overline{RESET}$ line for the bipolar ranges sets the ouput voltage to negative full scale.

DAC Register Contents MSB	LSB	Analog Output, V_{OUT}
0111	1111	$+V_{REF}\left(\frac{127}{128}\right)$
0000	0001	$+V_{REF}\left(\frac{1}{128}\right)$
0000	0000	0V
1111	1111	$-V_{REF}\left(\frac{1}{128}\right)$
1000	0001	$-V_{REF}\left(\frac{127}{128}\right)$
1000	0000	$-V_{REF}\left(\frac{128}{128}\right) = -V_{REF}$

NOTE: 1LSB = $(V_{REF})(2^{-7}) = V_{REF}$ (1/128)

Table V. Bipolar (−1.25V to +1.25V) Code Table

BIPOLAR (−2.5V to +2.5V) CONFIGURATION

The −2.5V to +2.5V bipolar output range is achieved by tying the RANGE input to V_{DD} and the V_{SS} input to −5V. Once again, the input coding is 2s complement. The table for output voltage versus digital code is as in Table V with $2.V_{REF}$ replacing V_{REF}. Note that for this range

$$1LSB = 4.V_{REF}(2^{-8}) = V_{REF}\frac{1}{64}$$

8

The analog input on the AD7569/AD7669 accepts the same four input ranges as the output ranges on the DAC. Whatever output range is selected for the DAC also applies to the input range of the ADC.

Although separate AGNDs exist for both the DAC and ADC to minimize crosstalk, writing data to the DAC while the ADC is performing a conversion may result in an incorrect conversion from the ADC due to an interaction of currents between the DAC and ADC. Therefore, to ensure correct operation of the ADC, the DAC register should not be updated while the ADC is converting.

UNIPOLAR OPERATION

The circuit of Figure 21 shows the AD7569 configured for both an input and output range of 0 to +1.25V (the AD7669 configuration is similar). The nominal transfer characteristic for this range is shown in Figure 22. The output code is Natural Binary with 1LSB = (1.25/256)V = 4.88mV.

As before, to achieve the unipolar 0 to +2.5V input range V_{SS} is connected to 0V and the RANGE input is tied to a logic high. The nominal transfer characteristic is as in Figure 22 but in this case ILSB = (2.5/256)V = 9.76mV.

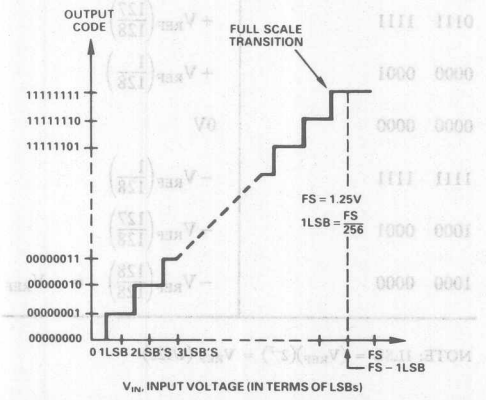

Figure 22. Nominal Transfer Characteristic for Unipolar (0 to +1.25V) Operation

BIPOLAR OPERATION

The analog input of the AD7569/AD7669 ADC is configured for bipolar inputs when V_{SS} = −5V. The output code provided by the part is 2s complement. Figure 23 shows the transfer function for bipolar (−1.25V to +1.25V) operation. The LSB size for this range is (2.5/256)V = 9.76mV.

The transfer function for the −2.5V to +2.5V range is identical to that of Figure 23 but now FS = 5V and the LSB size is (5/256)V = 19.5mV.

ADC OFFSET AND FULL-SCALE ERROR ADJUSTMENT

In most Digital Signal Processing (DSP) applications, offset and full-scale error have little or no effect on system performance. A

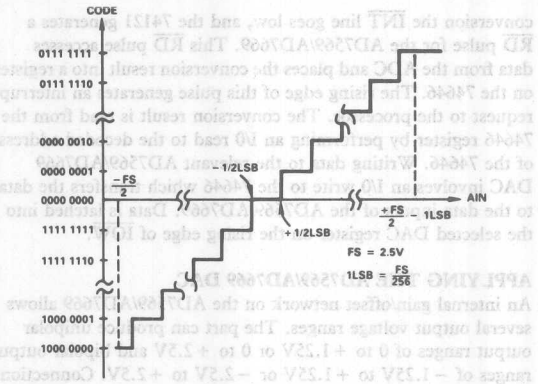

Figure 23. Nominal Transfer Characteristic for Bipolar (−1.25V to +1.25V) Operation

typical example is a digital filter, where an ac analog signal is quantized by the ADC, digitally processed and recreated using the DAC. In these type of applications the offset error can be eliminated by ac coupling the recreated signal. Full-scale error effect is linear and does not cause problems as long as the input signal is within the full dynamic range of the ADC. An important parameter in DSP applications is Differential Nonlinearity and this is not affected by either offset or full-scale error.

In applications where absolute accuracy is important then ADC offset and full-scale error can be adjusted to zero. Figure 24 shows the additional components required for offset and full-scale error adjustment. Offset error must be adjusted before full-scale error. Zero offset is achieved by adjusting the offset of the op amp driving V_{IN} (i.e., A1 in Figure 23). In unipolar applications, for zero offset error, apply 1/2LSB at the analog input and adjust the op amp offset voltage until the ADC output code flickers between 0000 0000 and 0000 0001. For zero full-scale error apply an analog input of FS – 3/2LSBs and adjust R1 until the ADC output code flickers between 1111 1110 and 1111 1111.

In bipolar applications, to adjust for bipolar zero offset apply −1/2LSB at the analog input and adjust the op amp offset voltage until the output code flickers between 1111 1111 and 0000 0000. For zero full-scale error apply +FS/2 – 3/2LSB at the analog input and adjust R1 until the ADC output code flickers between 01111110 and 0111 1111.

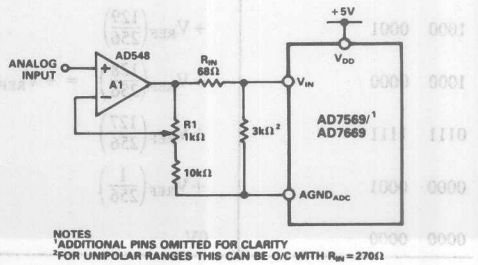

Figure 24. ADC Error Adjust Circuit

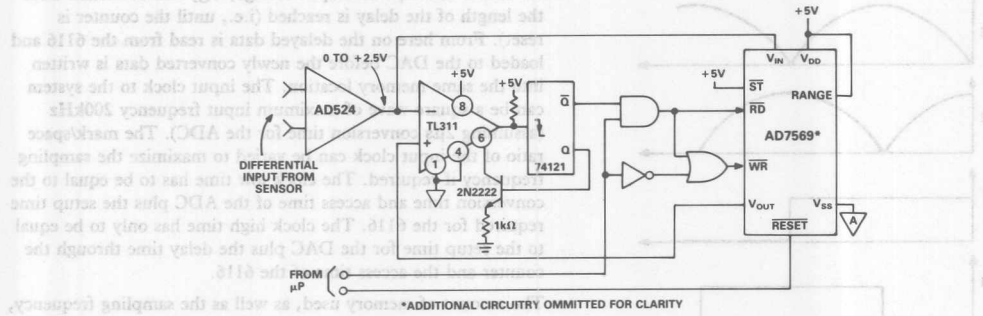

Figure 25. Peak-Reading A/D Converter

PEAK DETECTION – AD7569

The circuit of Figure 25 shows a peak-reading A/D converter which is useful in such applications as monitoring flow rates, temperature, pressure, etc. The circuit ensures that a peak will not be missed while at the same time does not require the microprocessor to frequently monitor the data. The peak value is stored in the A/D converter and can be read at any time.

The gain on the AD524 is adjusted to yield a 0 to +2.5V output. When the input signal exceeds the current stored value, the output of the TL311 goes low, triggering the $\overline{Q}$ output of the 74121. This low-going pulse starts a conversion on the AD7569 ADC and at the end of conversion latches the result into the DAC. This pulse must be at least 120ns greater than the conversion time of the ADC. The Q output is used to drive the strobe input of the TL311, resetting the TL311 output high in readiness for another conversion.

The additional gates on the $\overline{RD}$ and $\overline{WR}$ inputs are to allow the data to be read by the microprocessor while at the same time ensuring that the DAC is not updated when the microprocessor reads the data. It may be necessary to monitor the AD7569 $\overline{BUSY}$ line to ensure that a processor READ is not attempted while the AD7569 is in the middle of a conversion. The READ pulse width from the processor must be less than 1μs to ensure correct data is read from the ADC. A low-going pulse on the $\overline{RESET}$ line resets the DAC output to 0V and starts a new "peak-detection" period. This $\overline{RESET}$ pulse must also be less than 1μs.

DISK DRIVE APPLICATION – AD7669

Closed-Loop Microstepping

Microstepping is a popular technique in low density disk drives (both floppy and hard disk) which allows higher positional resolution of the disk drive head over that obtainable from a full-step driven stepper motor. Typically, a two-phase stepper motor has its phase currents driven with a sine-cosine relationship. These cosinusoidal signals are generated by two DACs driven with the appropriate data. The resolution of the DACs determines the number of microsteps into which each full step can be divided. For example, with a 1.8° full-step motor and a 4-bit DAC, a microstep size of 0.11° (1.8°/(2^n) is obtainable.

The microstepping technique improves the positioning resolution possible in any control application. However, the positional accuracy can be significantly worse than that offered by the original full-step accuracy specification due to load torque effects. To ensure that the increased resolution is useable, it is therefore necessary to use a closed-loop system where the position of the disk drive head (or motor) is monitored. The closed-loop system allows an error between the desired position and the actual position to be monitored and corrected. The correction is achieved by adjusting the ratio of the phase currents in the motor windings until the required head position is reached.

The AD7669 is ideally suited for the closed-loop microstepping technique with its on-chip dual DACs for positioning the disk drive head and on-board ADC for monitoring the position of the head. A generalized circuit for a closed-loop microstepping system is shown in Figure 26. The DAC waveforms are shown in Figure 27 along with the direction information for clockwise rotation supplied by the controller.

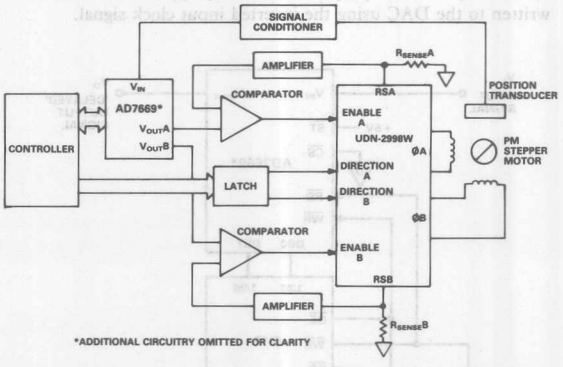

Figure 26. Typical Closed-Loop Microstepping Circuit with the AD7669

The AD7669 is used in the unipolar 0 to +2.5V configuration. This allows the circuit of Figure 26 to be completely unipolar (+5V, +12V supplies); no negative power supplies are required. The power output stage is a dual H-Bridge device such as the UDN-2998W from Sprague Electric. The phase currents in both windings are detected by means of the small value sense resistors, R_SA and R_SB, in series with the windings. The voltage developed across these resistors is amplified and compared with the respective DAC output voltage. The comparators in turn chop the phase winding current. The ADC completes the feedback path by converting information from a suitable transducer for analysis by the controller.

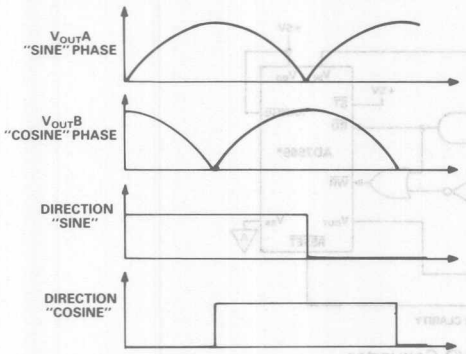

Figure 27. Typical DAC Output Voltages for Microstepping and Direction Signals for Clockwise Rotation with the UDN-2998W

ANALOG DELAY LINE – AD7569

In many applications, especially in audio systems, it is necessary to provide a delay on the input signal. The circuit of Figure 28 shows how a simple analog delay line can be implemented based on the AD7569. The input signal is sampled using the AD7569 ADC and converted data is loaded into the 6116 (2K × 8 static ram). The inverted input clock drives a counter which selects the address for the 6116. The delay is selected by choosing one of the output lines of the HCT4040 counter to reset the counter. This can be done using a simple switch in a manual system or by a multiplexer in a programmable delay application. Data is written to the DAC using the inverted input clock signal.

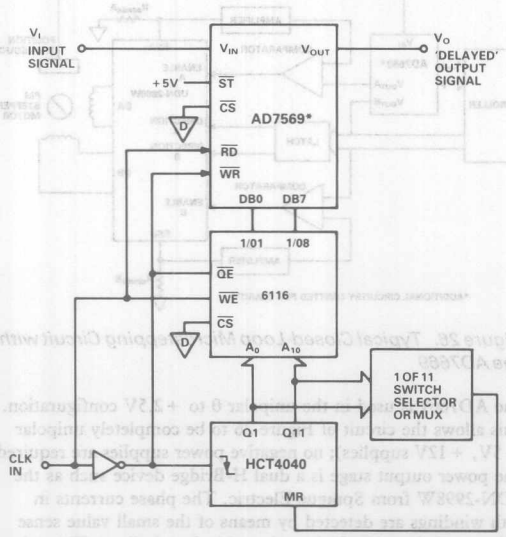

Figure 28. Analog Delay Line

On initial start-up the output voltage, V_O, will be invalid until the length of the delay is reached (i.e., until the counter is reset). From here on the delayed data is read from the 6116 and loaded to the DAC before the newly converted data is written into the same memory location. The input clock to the system can be a square wave of maximum input frequency 200kHz (assuming 2μs conversion time for the ADC). The mark/space ratio of the input clock can be varied to maximize the sampling frequency if required. The clock low time has to be equal to the conversion time and access time of the ADC plus the setup time required for the 6116. The clock high time has only to be equal to the setup time for the DAC plus the delay time through the counter and the access time of the 6116.

The amount of memory used, as well as the sampling frequency, determines the maximum possible delay. Using the HCT4040 and the 6116 with an input clock frequency of 200kHz, the maximum delay is 5ms on a maximum input frequency of 100kHz. Using 64K memory, with an 8kHz input clock frequency the maximum delay is 8 seconds on a maximum input frequency of 4kHz.

TRANSIENT RECORDER – AD7569

The scheme just outlined can also form the basis for a transient recorder. In this case transients on the input signal are converted and stored in memory. The transient can then be recalled from memory at a later time and the transient waveform can be recreated using the AD7569 DAC.

INFINITE SAMPLE-AND-HOLD – AD7569

The AD7569 is ideal for implementing a single-chip infinite sample-and-hold function. Basically, the ADC samples and converts the input signal into an 8-bit digital word. The 8 bits of data are then loaded to the DAC and the sampled value is restored to analog form. The sampled value is held until the DAC register is updated. The full-scale matching between the ADC and the DAC on the AD7569 ensures a typical error of less than 1% between the analog input voltage and the "held" output voltage. Figure 29 shows the connections required on the AD7569 to achieve this infinite sample-and-hold function.

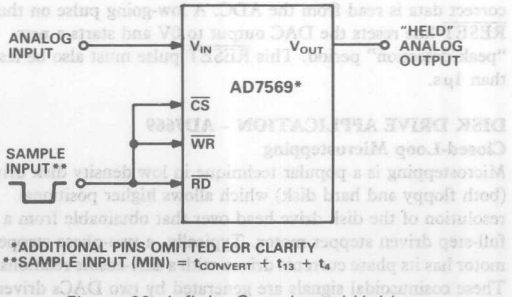

Figure 29. Infinite Sample-and-Hold

TARE FUNCTION FOR WEIGH SCALE – AD7569

The infinite sample-and-hold just outlined can also form the basis of a circuit to provide a tare function for a weigh scale system. Figure 30 shows a circuit for a weigh scale system. It incorporates a tare function using a simple circuit based on the AD7569.

The AD587 along with the 2N6285 provides a buffered +10V reference to supply the low impedance load cell transducer. The load cell output is amplified by the AD624 precision instrumentation amplifier with gain adjustment provided by R1. The output of the AD624 is applied to the noninverting input of a unity gain differential summing amplifier which uses the AD707, a high precision op amp with low drift. The AD707 feeds a 3 1/2 digit panel meter module which converts the signal for digital readout. The input signal to the panel meter is also applied to the analog input of the AD7569 for the tare function. When the tare switch (S1) is closed, a tare cycle commences and V_{IN} is sampled and held infinitely at V_{OUT} until the next tare cycle. V_{OUT} drives the inverting input of the differential amplifier and forces its output to zero. Thus, the tare function is used to give a readout of zero for any undesired weight, such as a box, when only the item placed in it is to be weighed. The tare function can also be used in calibrating the system, to cancel out offset errors due to the load cell, AD624 and differential amplifier.

The AD7569 offers many advantages in the system outlined, such as: simple, low cost circuit – no need for microprocessor, software, etc. – and low power consumption.

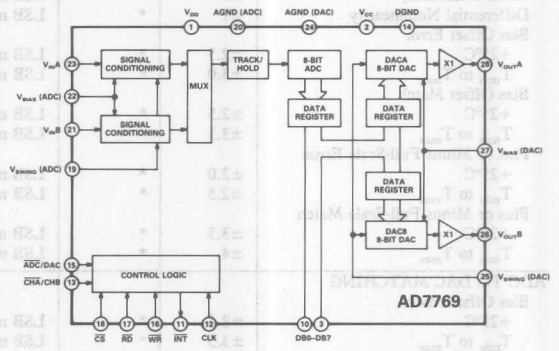
LC²MOS Analog I/O Port

AD7769*



FEATURES

Two-Channel, 8-Bit 2.5 μs ADC
Two 8-Bit, 2.5 μs DACs with Output Amplifiers
Span and Offset of ADC and DAC
Independently Adjustable
Low Power

APPLICATIONS

Winchester Disk Servo Controllers
Floppy Disk Microstepping
Closed Loop Servo Systems

FUNCTIONAL BLOCK DIAGRAM

GENERAL DESCRIPTION

The AD7769 is a complete, two-channel, 8-bit, analog I/O port. It has versatile input and output signal conditioning features that make it ideal for use in head-positioning servos in Winchester disk systems. It is equally suitable for floppy disk microstepping head positioning, other closed loop digital servo systems and general purpose 8-bit data acquisition.

The AD7769 contains a high speed successive approximation ADC, preceded by a two-channel multiplexer and signal conditioning circuits. The input span of the ADC and the offset of the zero point from ground can be independently set by applying ground referenced voltages. The AD7769 also contains two independent, fast settling, 8-bit DACs with output amplifiers. The output span and offset voltage of the DACs can be set independently of those of the ADC. This makes the AD7769 especially useful in disk drives, where only a positive supply rail is available and the ranges of the ADC and DACs must be referenced to some positive voltage less than the supply.

The AD7769 is easily interfaced to a standard 8-bit mpu bus via an 8-bit data port and standard microprocessor control lines.

The AD7769 is fabricated in Linear Compatible CMOS (LC²MOS), an advanced, mixed technology process that combines precision bipolar circuits with low power CMOS logic. The part is available in a 28-pin plastic DIP and 28-terminal PLCC package.

*Covered by U.S. Patent No. 4,990,916.

PRODUCT HIGHLIGHTS

1. Two-Channel, 8-Bit Analog I/O port on a Single Chip.
   The AD7769 contains a two-channel, high speed ADC with input signal conditioning and two, fast settling 8-bit DACs with output amplifiers, on a single chip.
2. Independent Control of Span and Offset.
   The input voltage span of the ADC and the midpoint of the transfer function, the output voltage swing of the two DACs and the half-scale output voltage, can be set independently by applying ground referenced control voltages.
3. Dynamic Specifications for DSP Users.
   In addition to the traditional ADC and DAC specifications, the AD7769 is specified with ac parameters including signal-to-noise ratio, distortion and signal bandwidth.
4. Fast Microprocessor Interface.
   The AD7669 has bus interface timing compatible with all modern microprocessors, with bus access and relinquish times less than 65 ns and a Write pulse width less than 90 ns.

NOTES
[1]See Figures 11, 12 and 13.
[2]Sample tested at +25°C to ensure compliance. All input signals are specified with tr = tf = 5 ns (10% to 90% of 5 V) and timed from a voltage level of 1.6 V.
[3]t_{10} and t_{13} are measured with the load circuits of Figure 1 and defined as the time required for an output to cross 0.8 V or 2.4 V.
[4]t_{14} is defined as the time required for the data lines to change 0.5 V when loaded with the circuits of Figure 2.
Specifications subject to change without notice.

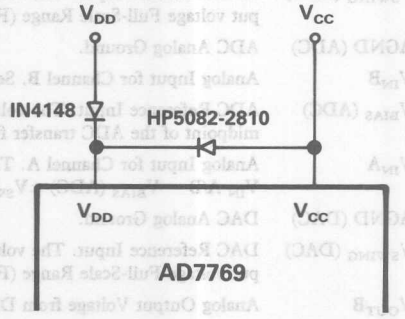
Lead Temperature (Soldering 10 secs) . . . . . +300°C

*Stresses above those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. This is a stress rating only and functional operation of the device at these or any other conditions above those listed in the operational sections of this specification is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability. Only one Absolute Maximum Rating may be applied at any one time.

CAUTION

ESD (electrostatic discharge) sensitive device. The digital control inputs are diode protected; however, permanent damage may occur on unconnected devices subject to high energy electrostatic fields. Unused devices must be stored in conductive foam or shunts. The protective foam should be discharged to the destination socket before devices are inserted.

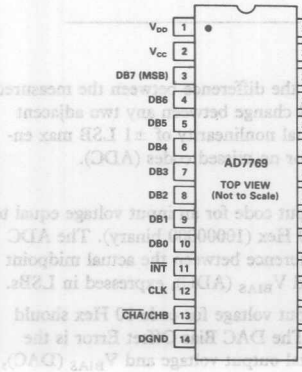


ORDERING GUIDE

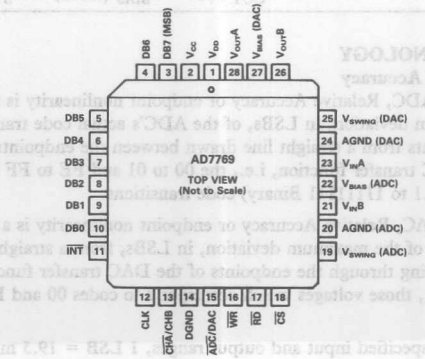
Model	Temperature Range	Package Option*
AD7769JN	0°C to +70°C	N-28
AD7769JP	0°C to +70°C	P-28A
AD7769AN	−40°C to +85°C	N-28
AD7769AP	−40°C to +85°C	P-28A

*N = Plastic DIP; P = Plastic Leaded Chip Carrier. For package outline information see Package Information section.

NOTE



Do not allow V_{CC} to exceed V_{DD} by more than 0.3 V. In cases where this can happen the diode protection scheme shown below is recommended.



8

PIN CONFIGURATION

DIP

PLCC

Pin	Mnemonic	Description
1	V_{DD}	+12 V Power Supply. This powers the analog circuitry.
2	V_{CC}	+5 V Power Supply. This powers the logic circuitry.
3–10	DB7–DB0	Input/Output Data Bus. A bidirectional data port from which ADC output data may be read and to which DAC input data may be written. DB7 is the Most Significant Bit.
11	$\overline{INT}$	Interrupt Output (active low). $\overline{INT}$ is set high on the falling edge of $\overline{RD}$ or $\overline{WR}$ to the ADC and goes low at the end of a conversion.
12	CLK	Clock input. A clock is required for the ADC. An external TTL-compatible clock may be applied to this input pin. Alternatively, tying this pin to V_{DD} enables the internal clock oscillator. With an external clock, the mark-space ratio can vary from 30/70 to 70/30.
13	$\overline{CHA}$/CHB	Channel A/Channel B Select Input. Selects Channel A or Channel B of the DAC or ADC. Used in conjunction with $\overline{WR}$, $\overline{RD}$, $\overline{CS}$ and $\overline{ADC}$/DAC for read or write operations.
14	DGND	Digital Ground.
15	$\overline{ADC}$/DAC	ADC or DAC Select Input. Selects either the ADC or the DAC for read or write operations in conjunction with $\overline{WR}$, $\overline{RD}$, $\overline{CS}$ and $\overline{CHA}$/CHB.
16	$\overline{WR}$	Write Input (edge triggered). This is used in conjunction with the $\overline{ADC}$/DAC, $\overline{CHA}$/CHB and $\overline{CS}$ control inputs to start an ADC conversion or write data to the DAC. An ADC conversion starts on the rising edge of $\overline{WR}$.
17	$\overline{RD}$	Read Input (active low). This input must be low to access data from the ADC.
18	$\overline{CS}$	Chip Select Input (active low). The device is selected when this input is low.
19	V_{SWING} (ADC)	ADC Reference Input. The voltage applied to this pin with respect to AGND (ADC) sets the input voltage Full-Scale Range (FSR) of the ADC. V_{IN} (FSR) = 2 V_{SWING} (ADC).
20	AGND (ADC)	ADC Analog Ground.
21	V_{IN}B	Analog Input for Channel B. See V_{IN}A description.
22	V_{BIAS} (ADC)	ADC Reference Input. The voltage applied to this pin with respect to AGND (ADC) sets the midpoint of the ADC transfer function.
23	V_{IN}A	Analog Input for Channel A. The input voltage range of both ADC channels is given by: V_{IN} A/B = V_{BIAS} (ADC) ±V_{SWING} (ADC).
24	AGND (DAC)	DAC Analog Ground.
25	V_{SWING} (DAC)	DAC Reference Input. The voltage applied to this pin with respect to AGND (DAC) sets the output voltage Full-Scale Range (FSR) of the DACs. V_{OUT} (FSR) = 2 V_{SWING} (DAC).
26	V_{OUT}B	Analog Output Voltage from DAC B. See V_{OUT}A description.
27	V_{BIAS} (DAC)	DAC Reference Input. The voltage applied to this pin with respect to AGND (DAC) sets the midpoint output voltage of the DACs.
28	V_{OUT}A	Analog Output Voltage from DAC A. The output voltage range of both DACs is given by: V_{OUT} A/B = V_{BIAS} (DAC) ± V_{SWING} (DAC).

TERMINOLOGY

Relative Accuracy

For an ADC, Relative Accuracy or endpoint nonlinearity is the maximum deviation, in LSBs, of the ADC's actual code transition points from a straight line drawn between the endpoints of the ADC transfer function, i.e., the 00 to 01 and FE to FF Hex (01111111 to 11111111 Binary) code transitions.

For a DAC, Relative Accuracy or endpoint nonlinearity is a measure of the maximum deviation, in LSBs, from a straight line passing through the endpoints of the DAC transfer function, i.e., those voltages which correspond to codes 00 and FF Hex.

For the specified input and output ranges, 1 LSB = 19.5 mV, but will vary with V_{SWING}. For both DACs and ADC, 1 LSB = 2 V_{SWING} / 256 = FSR / 256.

Differential Nonlinearity

Differential Nonlinearity is the difference between the measured change and the ideal 1 LSB change between any two adjacent codes. A specified differential nonlinearity of ±1 LSB max ensures monotonicity (DAC) or no missed codes (ADC).

Bias Offset Error

For an ideal ADC, the output code for an input voltage equal to V_{BIAS} (ADC), should be 80 Hex (10000000 binary). The ADC Bias Offset Error is the difference between the actual midpoint voltage for code 80 Hex and V_{BIAS} (ADC), expressed in LSBs.

For an ideal DAC, the output voltage for code 80 Hex should be equal to V_{BIAS} (DAC). The DAC Bias Offset Error is the difference between the actual output voltage and V_{BIAS} (DAC), expressed in LSBs.

Plus and Minus Full-Scale Error
The ADC and DACs in the AD7769 can be considered as devices with bipolar (plus and minus) input ranges, but referred to V_{BIAS} instead of AGND. Plus Full-Scale Error for the ADC is the difference between the actual input voltage at the FE to FF code transition and the ideal input voltage (V_{BIAS} + V_{SWING} −1.5 LSB), expressed in LSBs. Minus Full-Scale Error is similarly specified for the 01 to 00 code transition, relative to the ideal input voltage for this transition (V_{BIAS} − V_{SWING} +0.5 LSB). Plus Full-Scale Error for the DACs is the difference, expressed in LSBs, between the actual output voltage for input code FF and the ideal voltage (V_{BIAS} + V_{SWING} − 1 LSB). Minus Full-Scale Error is similarly specified for code 00, relative to the ideal output voltage (V_{BIAS} − V_{SWING}). Note that Plus and Minus Full-Scale errors for the ADC and the DAC outputs are measured after their respective Bias Offset errors have been adjusted out.

Digital-to-Analog Glitch Impulse
Digital-to-Analog Glitch Impulse is the impulse injected into the analog outputs when the digital inputs change state with either DAC selected. It is normally specified as the area of the glitch in nV secs and is measured when the digital input code is changed by 1 LSB at the major carry transition.

Digital Feedthrough
Digital Feedthrough is also a measure of the impulse injected into the analog outputs from the digital inputs but is measured when the DACs are not selected. It is essentially feedthrough across the die and package. It is important in the AD7769 since it is a measure of the glitch impulse transferred to the analog outputs when data is read from the ADC register. It is specified in nV secs and is measured with $\overline{WR}$ high and a digital code change from all 0s to all 1s.

Signal-to-Noise Ratio (SNR)
SNR is the measured Signal-to-Noise Ratio at the output of the converter. The signal is the rms magnitude of the fundamental. Noise is the rms sum of all the nonfundamental signals up to half the sampling frequency. SNR is dependent on the number of quantization levels used in the digitization process; the more levels, the smaller the quantization noise. The theoretical SNR for a sine wave is given by

$$SNR = (6.02N + 1.76)\ dB$$

where N is the number of bits. Thus for an ideal 8-bit converter, SNR = 49.92 dB.

Total Harmonic Distortion (THD)
THD is the ratio of the rms sum of harmonics to the fundamental. For the AD7769, Total Harmonic Distortion is defined as

$$20\ log\ \frac{(V_2^2 + V_3^2 + V_4^2 + V_5^2 + V_6^2)^{1/2}}{V_1}$$

where V_1 is the rms amplitude of the fundamental and V_2, V_3, V_4, V_5 and V_6 are the rms amplitudes of the individual harmonics.

Intermodulation Distortion (IMD)
With inputs consisting of sine waves at two frequencies, f_a and f_b, any active device with nonlinearities will create distortion products, of order (m+n), at sum and difference frequencies of mf_a+nf_b, where m, n = 0, 1, 2, 3 . . . Intermodulation terms are those for which m or n is not equal to zero. For example, the second order terms include (f_a+f_b) and (f_a-f_b) and the third order terms include ($2f_a+f_b$), ($2f_a-f_b$), (f_a+2f_b) and (f_a-2f_b).

1	X	X	X	X	High-Z	N/C	No Operation.

NOTES
[1]If $\overline{RD}$ = 1, DB0–DB7 will remain high impedance. If $\overline{RD}$ = 0, DB0–DB7 will output previous ADC data. The $\overline{RD}$ input should not change during a conversion.
[2]X = Don't Care.
[3]N/C = No Change.

CIRCUIT DESCRIPTION

Analog Inputs and Outputs

The AD7769 provides the analog-to-digital and digital-to-analog conversion functions required between the microcontroller and the servo power amplifier in digital servo systems. It is intended primarily for closed loop head positioning in Winchester disk drives but may also be used for microstepping in drives with stepper motor head positioning or other servo applications. The AD7769 contains a high speed, 8-bit, sampling ADC with two input channels and two 8-bit DACs with output buffer amplifiers. A unique feature of the AD7769 is the input and output signal conditioning circuitry which allows the analog input and output voltages to be referred to a point other than analog ground. The input range and offset of the ADC, the output swing and offset of the DACs may be adjusted independently by the application of ground-referenced, positive control voltages, V_{BIAS} (ADC), V_{SWING} (ADC), V_{BIAS} (DAC) and V_{SWING} (DAC). Thus, for example, the peak-to-peak output swing of the DACs could be set to 3 V above and 3 V below a bias voltage of 5 V.

Figures 5 and 6 show the transfer functions of the ADC and DACs and their relationship to V_{BIAS} and V_{SWING}. The mid-point code of the ADC, 80 Hex (10000000 Binary), occurs at an input voltage equal to V_{BIAS}. The input FSR of the ADC is equal to 2 V_{SWING}, so that the Plus Full-Scale code transition (FE to FF Hex) occurs at a voltage equal to V_{BIAS} + V_{SWING} −1.5 LSBs and the Minus Full-Scale code transition (01 to 00 Hex) occurs at a voltage V_{BIAS} − V_{SWING} +0.5 LSBs. The transfer function of the DACs bears a similar relationship to V_{BIAS} and V_{SWING}. The DAC output voltage for code 80 Hex (10000000 binary) is equal to V_{BIAS}, whilst FF Hex (11111111 binary) gives an output voltage of V_{BIAS} + V_{SWING} −1 LSB (Plus Full-Scale) and 00 Hex gives an output voltage of V_{BIAS} − V_{SWING} (Minus Full-Scale).

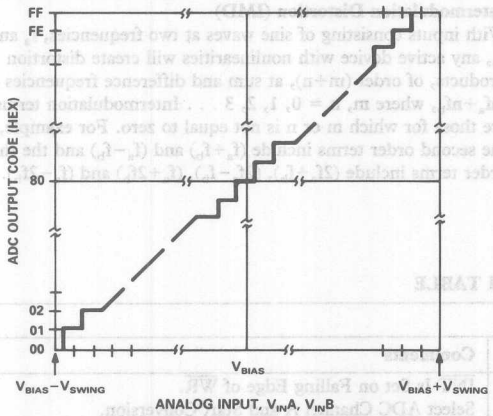

Figure 5. ADC Transfer Function

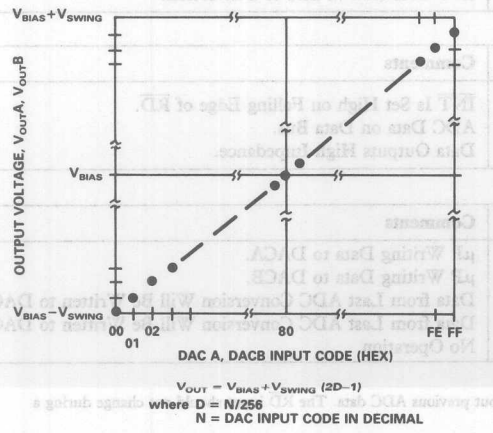

Figure 6. DAC Transfer Function

The ability to refer input and output signals to some voltage other than ground is of particular importance in disk drive applications. Typically, only +5 V digital and +12 V analog supply voltages are available, and the analog signals are often referred to a voltage around half the analog supply.

Driving the Analog Inputs and Reference Inputs

The analog inputs, $V_{IN}A$ and $V_{IN}B$, must be driven from low output impedance sources, such as from op amps. In addition, V_{BIAS} (ADC) must be driven from a similar type low impedance source (e.g., voltage reference).

Op amps are not required to drive the V_{SWING} (ADC), V_{BIAS} (DAC) and V_{SWING} (DAC) inputs as these are high impedance inputs (200 nA typical input current) that feed into on-chip buffer amplifiers. The reference voltages for these inputs can be derived using suitable resistor divider networks.

The analog reference available in the disk drive system can be used to set the bias voltage of the AD7769, and could also be attenuated to provide the reference for the input and output swing as shown in Figure 7. The same bias voltage would generally (though not necessarily) be used for the ADC and the DACs, though the input and output ranges might be different.

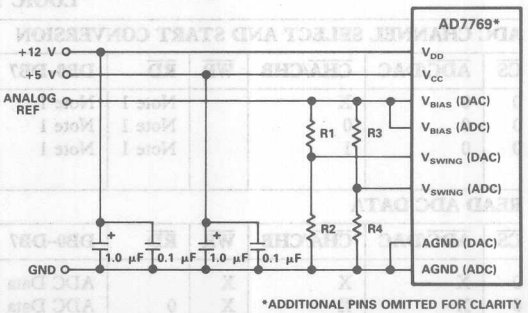

Figure 7. Typical Analog Connections to the AD7769

ADC Conversion Cycle

Figure 8 shows the operating waveforms for a conversion cycle. On the rising edge of $\overline{WR}$, the conversion cycle starts with the acquisition and tracking of the selected ADC channel, $V_{IN}A$ or $V_{IN}B$. The analog input voltage is held 50 ns (typically) after the fourth falling edge of the input CLK following a conversion start. If t_D in Figure 8 is greater than 150 ns, then the falling edge of the input CLK will be seen as the first falling clock edge. If t_D is less than 150 ns, the first falling clock edge to be recognized will not occur until one cycle later.

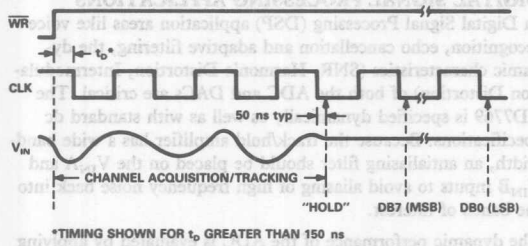

Figure 8. Operating Waveforms Using External Clock

Following the "hold" on the analog input, the MSB decision is made approximately 50 ns after the next falling edge of the input CLK. The succeeding bit decisions are made approximately 50 ns after a CLK edge until conversion is complete. At the end of conversion, the $\overline{INT}$ line goes low 100 ns (typically) after the LSB decision and the SAR contents are transferred to the output latch. The SAR is then reset in readiness for a new conversion.

Track-and-Hold

The track-and-hold (T/H) amplifier on the analog input to the ADC of the AD7769 allows the ADC to accurately convert an input sine wave of 5 V peak-to-peak amplitude up to a frequency of 200 kHz, the Nyquist frequency of the ADC when operated at its maximum throughput rate of 400 kHz. This maximum rate of conversion includes conversion time and time between conversions. Because the input bandwidth of the track-and-hold is much greater than 200 kHz, the input signal should be band limited to avoid folding unwanted signals into the band of interest.

DAC Outputs

The D/A converter outputs are buffered with on-board, high speed op amps that are capable of driving 5 kΩ and 100 pF loads to AGND (DAC). Each output amplifier settles to within 1/2 LSB of its final output value in typically less than 2.5 μs. See Figures 9 and 10 for waveforms of the typical output settling time performance.

The output noise from the amplifiers with full scale on the DACs is typically 200 μV peak-to-peak.

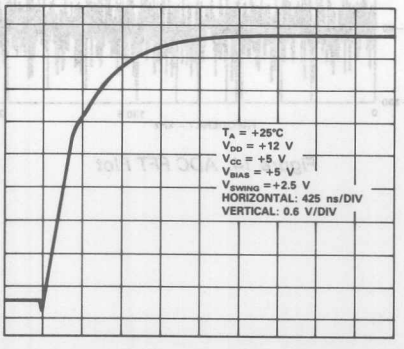

Figure 9. Positive-Going Settling Time

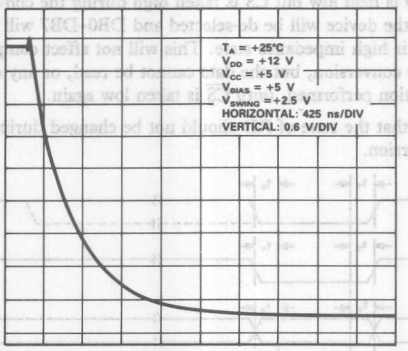

Figure 10. Negative-Going Settling Time

Internal / External Clock Operation

The AD7769 can be operated on either its own internal clock or with an externally applied clock signal . For internal clock operation the CLK input must be tied to V_{DD}. No external components are required. The internal clock typically runs at 5 MHz giving a typical conversion time of 2.5 μs. For external clock operation the CLK input must be driven with a TTL/HCMOS compatible input. The mark/space ratio of the clock signal can vary from 30/70 to 70/30. For an input frequency of 5 MHz, the conversion time is 2.5 μs.

Digital Inputs and Outputs

The AD7769 communicates over a standard, 8-bit microprocessor data bus and is controlled by standard mpu control lines, $\overline{CS}$, $\overline{WR}$, $\overline{RD}$, $\overline{INT}$, plus two address lines, $\overline{ADC}$/DAC and $\overline{CHA}$/CHB, which select the DAC or ADC function and Channel A or Channel B input/output channel. The Chip Select ($\overline{CS}$) line selects the device, Write ($\overline{WR}$) is used to initiate ADC conversions or to write data to the DAC, depending on the state of $\overline{ADC}$/DAC. $\overline{INT}$ is a status flag that indicates completion of a conversion, while $\overline{RD}$ is used to read ADC output data. The 8-bit data port (DB0-DB7) is a bidirectional port into which data can be written to the two DAC registers, and from which data can be read from the ADC register. ADC output data may also be written directly into either of the DAC registers.

These logical operations are detailed in Table I and in the timing diagrams, Figures 11 to 13. Figures 12 and 13 show the fairly straightforward operations of reading ADC data and writing data to the DACs, and need little explanation. Figure 11 shows the timing for ADC channel selection and conversion start. This is more complicated as the state of the data outputs during a conversion depends on $\overline{CS}$ and $\overline{RD}$.

To initiate a conversion (or any other operation) the device must be selected by taking $\overline{CS}$ low. A conversion is started by taking $\overline{WR}$ low, then high again (conversion starts on rising edge of $\overline{WR}$). There are three possibilities for the state of the data outputs during the conversion.

1. If $\overline{RD}$ is held high, the data outputs will be high impedance throughout the conversion.
2. If $\overline{RD}$ and $\overline{CS}$ are both held low until after $\overline{INT}$ goes low, then DB0–DB7 will initially output data from the last conversion. After $\overline{INT}$ goes low the new conversion data will appear on DB0–DB7.

8

sion, the device will be de-selected and DB0–DB7 will revert to their high impedance state. This will not affect completion of the conversion, but the data cannot be read, or any other operation performed, until $\overline{CS}$ is taken low again.

4. Note that the state of $\overline{RD}$ should not be changed during a conversion.

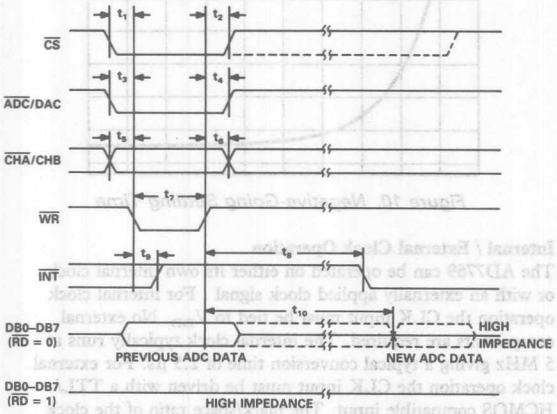

Figure 11. Timing for ADC Channel Select and Conversion Start

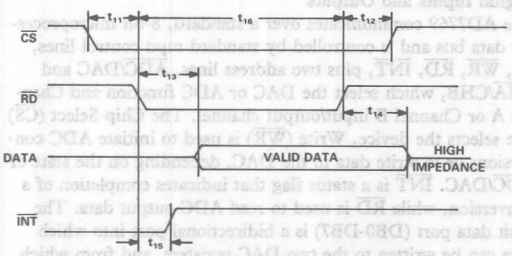

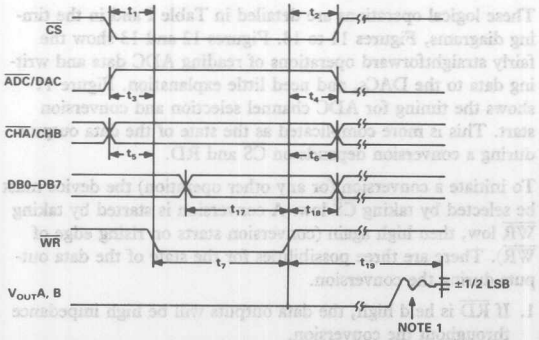

Figure 12. Timing for ADC Data Read

NOTE 1. THE TIME AXIS IS COMPRESSED FOR THIS SECTION OF THE DIAGRAM

Figure 13. Timing for DAC Channel Select and Data Write

In Digital Signal Processing (DSP) application areas like voice recognition, echo cancellation and adaptive filtering, the dynamic characteristics (SNR, Harmonic Distortion, Intermodulation Distortion) of both the ADC and DACs are critical. The AD7769 is specified dynamically as well as with standard dc specifications. Because the track/hold amplifier has a wide bandwidth, an antialiasing filter should be placed on the $V_{IN}A$ and $V_{IN}B$ inputs to avoid aliasing of high frequency noise back into the bands of interest.

The dynamic performance of the ADC is evaluated by applying a sine wave signal of very low distortion to the $V_{IN}A$ or $V_{IN}B$ input which is sampled at a 409.6 kHz sampling rate. A Fast Fourier Transform (FFT) plot or Histogram plot is then generated from which SNR, harmonic distortion and dynamic differential nonlinearity data can be obtained. For the DACs, the codes for an ideal sine wave are stored in PROM and loaded down to the DAC. The output spectrum is analyzed, using a spectrum analyzer to evaluate SNR and harmonic distortion performance. Similarly, for intermodulation distortion, an input (either to VIN or DAC code) consisting of pure sine waves at two frequencies is applied to the AD7769.

Figure 14 shows a 2048 point FFT plot of the ADC with an input signal of 130 kHz. The SNR is 49.2 dB. It can be seen that most of the harmonics are buried in the noise floor. It should be noted that the harmonics are taken into account when calculating the SNR. The relationship between SNR and resolution (N) is expressed by the following equation:

$$SNR = (6.02N + 1.76)\ dB$$

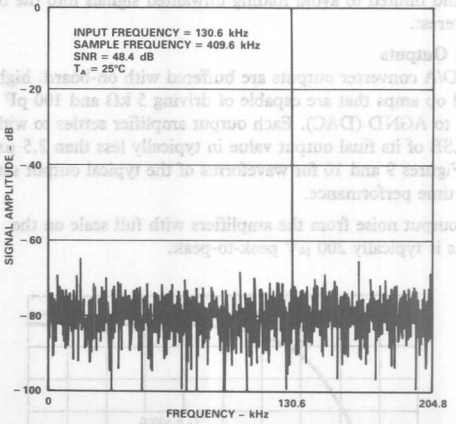

Figure 14. ADC FFT Plot

This is for an ideal part with no differential or integral linearity errors. These errors will cause a degradation in SNR. By working backwards from the above equation, it is possible to get a measure of ADC performance expressed in effective number of bits (N). The effective number of bits is plotted versus frequency in Figure 15. The effective number of bits typically falls between 7.7 and 7.9, corresponding to SNR Figures 48.1 and 49.7 dB.

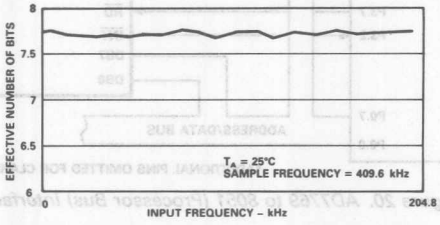

Figure 15. Effective Number of Bits vs. Frequency

Figure 16 shows a spectrum analyzer plot of the output spectrum from one of the DACs with an ideal sine wave table loaded to the data inputs of the DAC. In this case, the SNR is 47 dB.

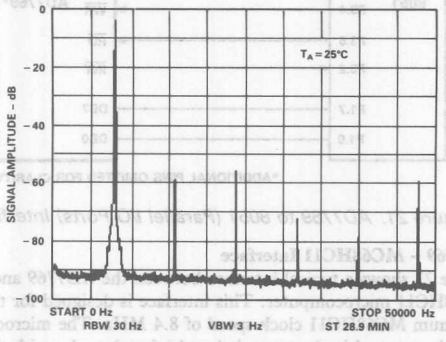

Figure 16. DAC Output Spectrum

Histogram Plot

When a sine wave of specified frequency is applied to the $V_{IN}A$ or $V_{IN}B$ input of the AD7769 and several thousand samples are taken, it is possible to plot a histogram showing the frequency of occurrence of each of the 256 ADC codes. If a particular step is wider than the ideal 1 LSB width, then the code associated with that step will accumulate more counts than for the code for an ideal step. Likewise, a step narrower than ideal width will have fewer counts. Missing codes are easily seen because a missing code means zero counts for a particular code. The absence of large spikes in the plot indicates small differential nonlinearity.

Figure 17 shows a histogram plot for the ADC indicating very small differential nonlinearity and no missing codes for an input frequency of 204 kHz. For a sine wave input, a perfect ADC would produce a probability density function described by the equation:

$$p(V) = \frac{1}{\pi (A^2 - V^2)^{1/2}}$$

where A is the peak amplitude of the sine wave and p (V) the probability of occurrence at a voltage V. The histogram plot of Figure 17 corresponds very well with this shape.

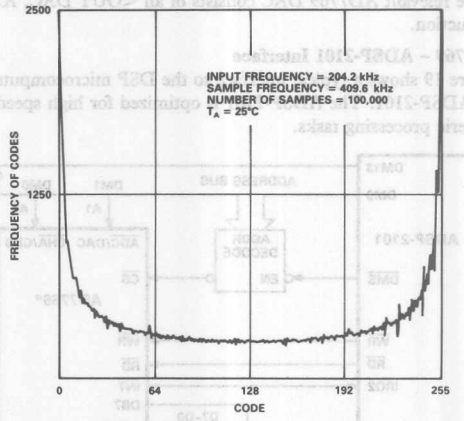

Figure 17. ADC Histogram Plot

In digital signal processing applications, where the AD7769 is used to sample AC signals, it is essential that the signal sampling occurs at exactly equal intervals. This minimizes errors due to sampling uncertainty or jitter. A precise timer or clock source, to start the conversion process, is the best method of generating equidistant sampling intervals.

MICROPROCESSOR / MICROCOMPUTER INTERFACING

The AD7769 is designed for easy interfacing to microprocessors and microcomputers as a memory mapped peripheral or an I/O device. In addition, the AD7769 high speed bus timing allows direct interfacing to many DSP processors such as the TMS320C10 and ADSP-2101.

AD7769 – TMS320C10 Interface

A typical interface to the TMS320C10 is shown in Figure 18. The AD7769 is mapped at a port address, and the interface is designed for the maximum TMS320C10 clock frequency of 20 MHz.

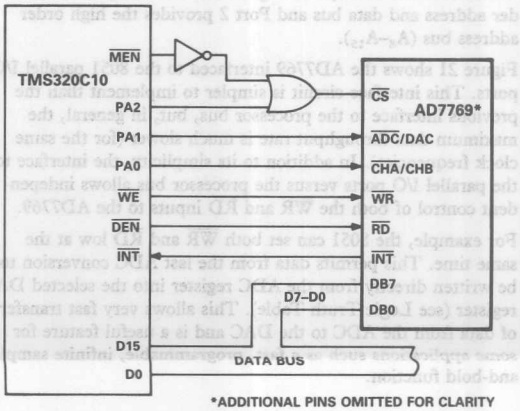

Figure 18. AD7769 to TMS320C10 Interface

8

Conversion is initiated on the selected AD7769 ADC channel using a single I/O instruction, <OUT ADC, A>. The processor then polls $\overline{INT}$ until it goes low before reading the conversion result using an <IN A, ADC> instruction. Writing data to the relevant AD7769 DAC consists of an <OUT DAC, A> instruction.

AD7769 – ADSP-2101 Interface

Figure 19 shows a typical interface to the DSP microcomputer, the ADSP-2101. The ADSP-2101 is optimized for high speed numeric processing tasks.

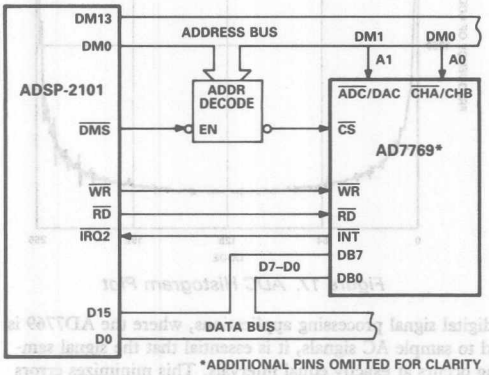

Figure 19. AD7769 to ADSP-2101 Interface

Because the instruction cycle of the ADSP-2101 is very fast (80 ns cycle), the $\overline{WR}$ and $\overline{RD}$ pulses must be stretched out to suit the AD7769. This is easily achieved as the ADSP-2101 memory interface supports slower memories and memory-mapped peripherals (i.e., AD7769) with a programmable wait state generation capability. A number of wait states, from 0 to 7, can be specified for each memory interface. One wait state is sufficient for the interface to the AD7769.

AD7769 – 8051 Interface

A choice of two interface modes are available to the 8051 microcomputer.

Figure 20 shows a typical interface to the 8051 processor bus. It is suitable for the maximum 8051 clock frequency of 12 MHz. In this interface mode, Port 0 provides the multiplexed low order address and data bus and Port 2 provides the high order address bus (A_8–A_{15}).

Figure 21 shows the AD7769 interfaced to the 8051 parallel I/O ports. This interface circuit is simpler to implement than the previous interface to the processor bus, but, in general, the maximum data throughput rate is much slower (for the same clock frequencies). In addition to its simplicity, the interface to the parallel I/O ports versus the processor bus allows independent control of both the $\overline{WR}$ and $\overline{RD}$ inputs to the AD7769.

For example, the 8051 can set both $\overline{WR}$ and $\overline{RD}$ low at the same time. This permits data from the last ADC conversion to be written directly from the ADC register into the selected DAC register (see Logic Truth Table). This allows very fast transfer of data from the ADC to the DAC and is a useful feature for some applications such as a fast, programmable, infinite sample-and-hold function.

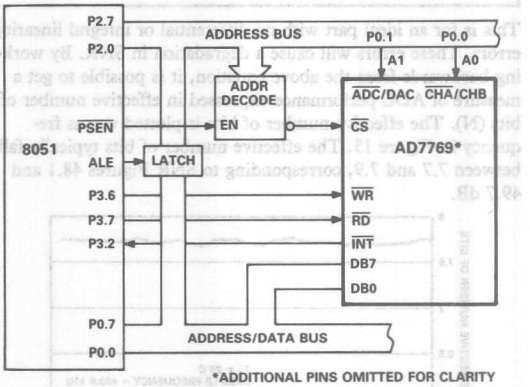

Figure 20. AD7769 to 8051 (Processor Bus) Interface

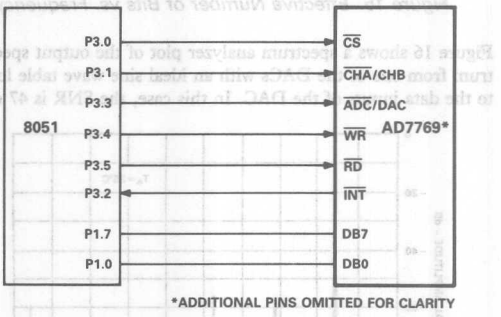

Figure 21. AD7769 to 8051 (Parallel I/O Ports) Interface

AD7769 – MC68HC11 Interface

Figure 22 shows a typical interface between the AD7769 and the MC68HC11 microcomputer. This interface is designed for the maximum MC68HC11 clock speed of 8.4 MHz. The microcomputer is operated in the expanded multiplexed mode, with the AD7769 as a memory mapped peripheral. The expansion bus is made up of Ports B and C, and control signals AS and R/$\overline{W}$.

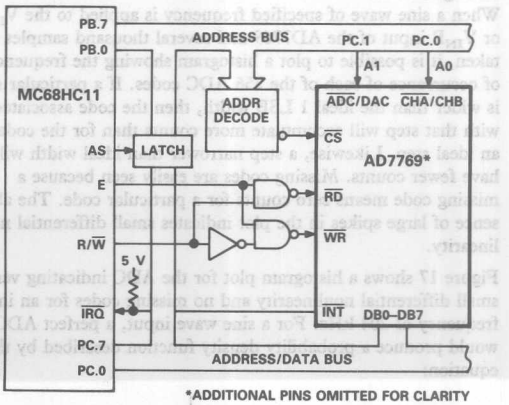

Figure 22. AD7769 to MC68HC11 Interfaced

APPLICATIONS

The AD7769 analog I/O port is used to convert servo related signals between the analog and digital domains. The input structure of the two-channel ADC makes it very easy to convert the typical output signals provided by a servo demodulator.

In a magnetic disk drive employing a dedicated servo surface, the servo demodulator produces two, positive-only, quadrature signals, generally sinusoidal or triangular, from the di-bit patterns read from the servo surface. The quadrature signals have the form of $V_{BIAS} \pm V_{SWING}$. The very fast conversion time of the AD7769 ADC allows sequential conversion of these quadrature signals without introducing significant phase delay errors. These converted signals provide the servo microcontroller with position and track crossing information from which velocity information can be derived. In optical disk drives, analogous servo signals can be derived from the quad photodiode detector to provide position and focus information for the microcontroller.

The two DACs in the AD7769 accept servo data from the microcontroller to position the head assembly. The DACs provide positive-only output signals of the form $V_{BIAS} \pm V_{SWING}$, which are ideal for driving voice coil motors. In magnetic disk drives, a single voice coil motor is used to position the head assembly and one DAC is usually sufficient to drive the motor in both the seek and track modes. In the seek mode, the DAC can be used to generate directly the desired analog velocity trajectory which the head must travel in order to achieve minimum access times. Alternatively, the DAC can generate a servo error value (computed by the microcontroller) between the actual head velocity and the desired head velocity. In the track mode, the DAC can be used to provide a position error signal to keep the head over the track or to detent the head off track, for such purposes as thermal compensation and soft error retries. The second DAC in the AD7769 may be employed in this fine positioning loop. Alternatively, the second DAC can be used to control the speed of the spindle motor via a pulse width modulator. In optical disk drives two voice coil motors are used, requiring both DACs of the AD7769—one for the focus servo loop and one for the radial positioning servo loop.

A typical servo control loop using the AD7769 is shown in Figure 23. In this dedicated servo drive, the servo demodulator converts the servo information bit patterns from the disk into the standard N and Q (normal and quadrature) servo signals. The voice coil motor current, I_L, is bidirectional and is supplied by the power transconductance amplifier. One input to this amplifier is held at V_{BIAS} (DAC), while the other input is driven from a DAC output, V_{OUT} A/B. Typical input/output waveforms for this power stage are shown in Figure 24. The transconductance, G_O, of the power stage is determined by external sense resistors.

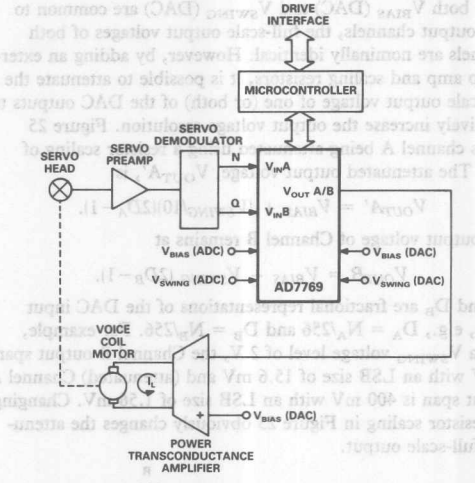

Figure 23. Typical Dedicated Servo Control Loop Using the AD7769

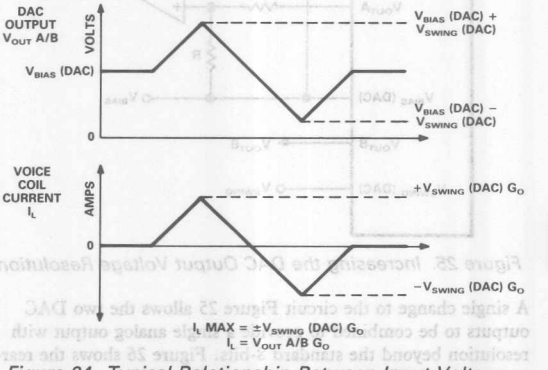

Figure 24. Typical Relationship Between Input Voltage and Output Current for Transconductance Amplifier

8

Increased Resolution DAC Output

Since both V_{BIAS} (DAC) and V_{SWING} (DAC) are common to both output channels, the full-scale output voltages of both channels are nominally identical. However, by adding an external op amp and scaling resistors, it is possible to attenuate the full-scale output voltage of one (or both) of the DAC outputs to effectively increase the output voltage resolution. Figure 25 shows channel A being attenuated using a resistor scaling of 10:1. The attenuated output voltage, $V_{OUT}A'$, is

$$V_{OUT}A' = V_{BIAS} + (V_{SWING}/10)(2D_A - 1).$$

The output voltage of Channel B remains at

$$V_{OUT}B = V_{BIAS} + V_{SWING}\,(2D_B - 1).$$

D_A and D_B are fractional representations of the DAC input codes, e.g., $D_A = N_A/256$ and $D_B = N_B/256$. For example, with a V_{SWING} voltage level of 2 V, the Channel B output span is 4 V with an LSB size of 15.6 mV and (attenuated) Channel A output span is 400 mV with an LSB size of 1.56 mV. Changing the resistor scaling in Figure 25 obviously changes the attenuated full-scale output.

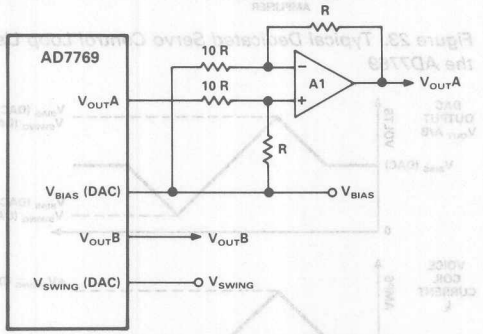

Figure 25. Increasing the DAC Output Voltage Resolution

A single change to the circuit Figure 25 allows the two DAC outputs to be combined to provide a single analog output with resolution beyond the standard 8-bits. Figure 26 shows the rearranged circuit. The composite output, V_{OUT}, is

$$V_{OUT} = V_{OUT}B + (V_{SWING}/10)(2D_A - 1)$$

or

$$V_{OUT} = V_{BIAS} + V_{SWING}\,(2D_B - 1) + (V_{SWING}/10)\,(2D_A - 1).$$

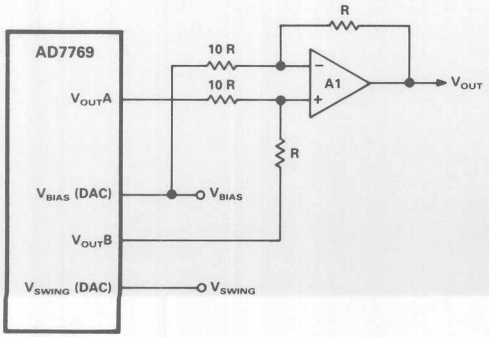

Figure 26. Combined $V_{OUT}A$, $V_{OUT}B$ Circuit

DAC A can be programmed to produce an interpolation function between the 8-bit steps of DAC B to allow, for example, very smooth velocity profile waveforms to be generated.

Servo Offset Facility

Most dedicated servo disk drives offer an offset facility whereby some small voltage is injected into the track-following loop. The purpose of the offset is to move the head to the right or left of its current on-track position to permit reading of off-track data. The circuit is shown in Figure 27. With the 10:1 resistor scaling used in the circuit the output voltage, V_{OUT}, is

$$V_{OUT} = V_{PE} + (V_{SWING}/10)\,(2D_A - 1).$$

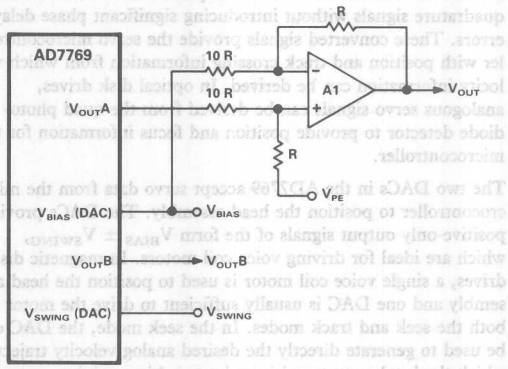

Figure 27. Servo Offset Facility

With no offset added, $V_{OUT} = V_{PE}$, where V_{PE} is the position error voltage which the servo loop normally drives to its zero level, V_{BIAS}. When an offset voltage is supplied by DAC A, the action of the servo is to move the head away from its current on-track position until the position error voltage is equal and opposite to the offset voltage. The position of the head about the track centre is thus programmable.

Programmable Full-Scale Range

The output voltage span of both DACs is determined by the V_{SWING} (DAC) voltage level. This is normally supplied from some fixed voltage source. However, it is possible to use one of the DAC channels to generate a programmable V_{SWING} voltage level. The remaining channel will thus have a full-scale range and LSB size which is software programmable. This circuit is shown in Figure 28 where $V_{OUT}B$ is used in an implicit feedback loop to generate a programmable swing voltage, V_{SWING} (DAC), for the AD7769 from an external fixed input swing voltage, V_{SWING}. Using the 5:1 resistor scaling shown in Figure 28, the expression for the AD7669 input swing voltage is

$$V_{SWING}\,(DAC) = \frac{V_{SWING}}{1 - \dfrac{(2D_B - 1)}{5}}.$$

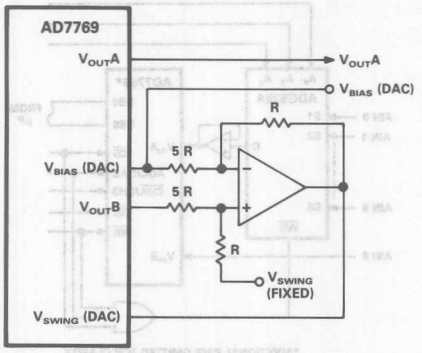

Figure 28. Generating a Software Programmable V_{SWING} (DAC)

For example, with a fixed input swing voltage of 2.5 V, the programmable span via DAC B is as follows:

$D_B = 0$: V_{SWING} (DAC) = 2.08

$D_B = 1/2$: V_{SWING} (DAC) = 2.5 V = V_{SWING}

$D_B \approx 1$: V_{SWING} (DAC) = 3.125 V

The AD7769 is specified for a V_{SWING} (DAC) voltage range from 2 V to 3 V, although in practice this range can be extended while still maintaining monotonic operation.

Closed Loop Microstepping

Microstepping is a popular technique in low density disk drives (both floppy and hard disk) which allows higher positional resolution of the disk drive head over that obtainable from a full-step driven stepper motor. Typically, a two-phase stepper motor has its phase currents driven with a sine-cosine relationship. These cosinusoidal signals are generated by two DACs driven with the appropriate data. The resolution of the DACs determines the number of microsteps into which each full step can be divided. For example, with a 1.8° full-step motor and a 4-bit DAC, a microstep size of 0.11° (1.8°/2^n) is obtainable.

The microstepping technique improves the positioning resolution possible in any control application. However, the positional accuracy can be significantly worse than that offered by the original full-step accuracy specification due to load torque effects. To ensure that the increased resolution is useable, it is therefore necessary to use a closed-loop system where the position of the disk drive head (or motor) is monitored. The closed-loop system allows an error between the desired position and the actual position to be monitored and corrected. The correction is achieved by adjusting the ratio of the phase currents in the motor windings until the required head position is reached.

The AD7769 is ideally suited for the closed-loop microstepping technique with its dual DACs for positioning the disk drive head and dual channel ADC for monitoring the position of the head. A typical circuit for a closed-loop microstepping system is shown in Figure 29. The DAC waveforms are shown in Figure 30 along with the direction information of clockwise rotation supplied by the controller.

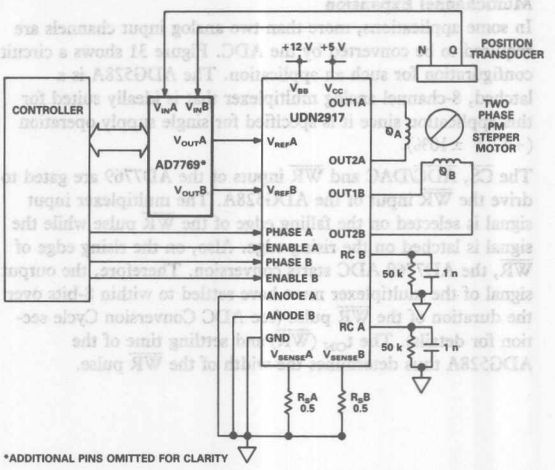

Figure 29. Typical Closed-Loop Microstepping Circuit with the AD7769

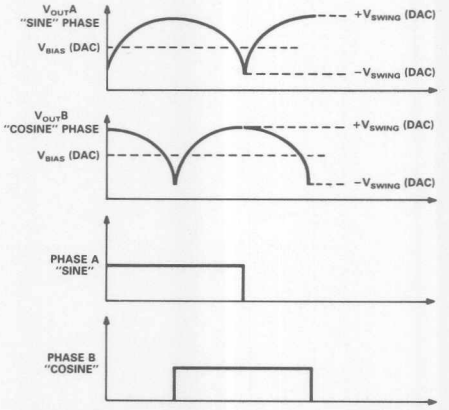

Figure 30. Typical Control Waveforms for the Microstepping Circuit of Figure 29

A typical transducer would be a moire-fringe transducer which consists of two gratings, one fixed and one moveable. The relative positions of these two gratings will modulate the amount of light from a LED which can pass through. In order to derive head direction information the stationary grating has two sets of bars, with a 90° phase relationship, and two photo-transistors. The quadrature sinusoidal output waveforms (N & Q) can be converted directly by the AD7769.

8

Multichannel Expansion

In some applications, more than two analog input channels are required to be converted by the ADC. Figure 31 shows a circuit configuration for such an application. The ADG528A is a latched, 8-channel analog multiplexer that is ideally suited for this application since it is specified for single supply operation (+12 V ±10%).

The $\overline{CS}$, $\overline{ADC}$/DAC and $\overline{WR}$ inputs of the AD7769 are gated to drive the $\overline{WR}$ input of the ADG528A. The multiplexer input signal is selected on the falling edge of the $\overline{WR}$ pulse while the signal is latched on the rising edge. Also, on the rising edge of $\overline{WR}$, the AD7769 ADC starts conversion. Therefore, the output signal of the multiplexer must have settled to within 8-bits over the duration of the $\overline{WR}$ pulse (see ADC Conversion Cycle section for details). The t_{ON} ($\overline{WR}$) and settling time of the ADG528A thus determines the width of the $\overline{WR}$ pulse.

LC²MOS Complete Embedded Servo Front Ends for HDD

AD7773/AD7775*

FEATURES
10-Bit, 3 µs ADC
Two DACs with Output Amplifiers
One 10-Bit, 4 µs Settling DAC
One 8-Bit, 3 µs Settling DAC
Fully Integrated Burst Detector
Power-Down Mode
+5 V Only
Fast Interface Port
28-Pin SOIC Package

APPLICATIONS
Embedded Servo For HDD
Combined Dedicated /Embedded Servo

FUNCTIONAL BLOCK DIAGRAM

PRELIMINARY TECHNICAL DATA

GENERAL DESCRIPTION

The AD7773 and AD7775 provide all the functionality necessary to implement the servo demodulator and head positioning tasks in embedded servo systems. A power-down mode which turns all the linear circuitry OFF enhances the use of the AD7773 and AD7775 in portable systems.

The demodulator channel can capture high speed servo data from a variety of embedded servo patterns. Up to four sequential servo burst signals can be synchronously demodulated, full-wave rectified and integrated. At the end of a burst period the integrated output voltage, representing the amplitude of a captured burst, is sampled and held on one of four internal track/hold amplifiers prior to conversion. After conversion the digitized burst signals from the ADC are fed to four 10-bit wide data registers.

The AD7773 and AD7775 also contain two independent voltage-output DACs: one with 10-bit resolution and one with 8-bit resolution. The two DACs produce output signals of the form $V_{BIAS} \pm V_{SWING}$ where V_{BIAS} and V_{SWING} are internally generated on-chip. The V_{BIAS} signal is available externally on the REFOUT pin.

The devices are easily interfaced to popular DSP processors and microcontrollers. The AD7773 has a 10-bit data port with separate address pins. The AD7775 has a 10-bit multiplexed address/data bus with an ALE input to latch the address.

The AD7773 and AD7775 are fabricated in linear compatible CMOS (LC²CMOS), an advanced, mixed technology process that combines precision bipolar circuits with low power CMOS logic. The devices are available in 28-pin SOIC packages.

NOTES

[1]See Figures 4 and 5.

[2]Timing specifications in **bold print** are 100% production tested. All other times are sample tested at +25°C to ensure compliance. All input signals are specified with $t_r = t_f$ = 5 ns (10% to 90% of 5 V) and timed from a voltage level of 1.6 V.

[3]Data access time depends directly on t_4, the $\overline{CS}$ to $\overline{RD}$ setup time, e.g., $t_{11} = 100 - t_4$. Time t_{11} is measured with the load circuit of Figure 3 and is defined as the time required for an output to cross 0.8 V or 2.4 V.

[4]t_{12} is derived from the measured time taken by the data outputs to change 0.5 V when loaded with the circuit of Figure 3. The measured number is then extrapolated back to remove the effects of charging or discharging the 100 pF capacitor. This means that the time t_{12} quoted above is the true bus relinquish time of the device and, as such, is independent of external bus loading capacitance.

Specifications subject to change without notice.

*Stresses above those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. This is a stress rating only and functional operation of the device at these or any other conditions above those listed in the operational sections of this specification is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability. Only one Absolute Maximum Rating may be applied at any one time.

ORDERING GUIDE

Model	Temperature Range	Package Option*
AD7773JR	0°C to +70°C	R-28
AD7775JR	0°C to +70°C	R-28

*R = Small Outline IC (SOIC). For outline information see Package Information section.

CAUTION

ESD (electrostatic discharge) sensitive device. The digital control inputs are diode protected; however, permanent damage may occur on unconnected devices subject to high energy electrostatic fields. Unused devices must be stored in conductive foam or shunts. The protective foam should be discharged to the destination socket before devices are inserted.

PIN FUNCTION DESCRIPTION

Pin	Mnemonic	Description
Power Supplies		
25	V_{CC}	+5 V Power Supply.
9	DGND	Digital Ground.
16 and 23	AGND	Analog Ground.
Microprocessor Interface		
28	$\overline{RD}$	Read Input (Active Low). When active it is used in conjunction with $\overline{CS}$ to read data over the Input/Output bus. See the truth tables for Microprocessor Interfacing.
27	$\overline{WR}$	Write Input (Active Low). When active it is used in conjunction with $\overline{CS}$ to write data over the Input/Output bus.
26	$\overline{CS}$	Chip Select Input (Active Low). The device is selected when this input is low.
Microprocessor Interface—AD7773 Only		
4–8 and 10–14	DB0–DB4, DB5–DB9	Input/Output Data Bus. A 10-bit wide bidirectional data port over which data is transferred into or out of the AD7773. DB0 is the Least Significant Bit.
2	A0	Address Inputs A0 and A1 select one of four registers. See Table I for details.
1	A1	
Microprocessor Interface—AD7775 Only		
4–8 and 10–14	AD0–DB4, DB5–DB9	Multiplexed Address/Data Input/Output Bus. An ALE signal is used to demultiplex the bus. After the falling edge of ALE the address present on AD0–AD3 must be removed and $\overline{WR}$ or $\overline{RD}$ exercised to complete the instruction. The bus now transfers 10 bits of data into or out of the AD7775. AD0 is the Least Significant Bit.
2	ALE	Address Latch Enable Input used to demultiplex the address/data bus. On the falling edge of ALE address inputs AD1–AD3 are internally latched (AD0 is a don't care) and remain latched until ALE returns High. See Table II for details.
1	$\overline{RESET}$	Reset Input (Active Low). Used as a hardware reset for various functional blocks: Loads half-scale code into both DAC registers. Resets the internal ADC register stack Write Pointer to the bottom-most register. Loads Control Register with 364 (Hex). See Control Register Description. Loads Status Register with 3E0 (Hex). See Status Register Description.
Demodulator Channel		
19	$V_{IN}(+)$	Differential Inputs to the input amplifier. Analog input signals to these pins should be capac-
20	$V_{IN}(-)$	itively coupled.
22	$C_{INT}(+)$	The value of capacitor connected between these pins sets the integrator time constant. See
21	$C_{INT}(-)$	under Design Information for choosing the C_{INT} capacitor.
24	CTRL	Control Input. All signal capture operations are controlled by this input. The number of CTRL pulses applied to the device must equal the number of bursts to be captured.
3	CLKIN	Clock input. A clock is required for the ADC. An external TTL-compatible clock must be applied to this input pin. See the T_{CLKIN} specifications for CLKIN information.
Analog Outputs		Each of the two DACs has the same output voltage range given by: $V_{OUT} = V_{BIAS} \pm V_{SWING} = REFOUT \pm V_{SWING}$ With midcode in either DAC register the respective DAC output is equal to REFOUT.
15	$V_{OUT}A$	Analog Output Voltage from DAC A. 1 LSB = 2 V_{SWING}/1024 = REFOUT/1024 =2.1 mV.
18	$V_{OUT}B$	Analog Output Voltage from DAC B. 1 LSB = 2 V_{SWING}/256 = REFOUT/256 = 8.6 mV.
17	REFOUT	Voltage Reference Output. Internally this is used as the reference for the ADC and as the bias level (V_{BIAS}) for the two DACs.

PRELIMINARY TECHNICAL DATA

This information applies to a product under development. Its characteristics and specifications are subject to change without notice. Analog Devices assumes no obligation regarding future manufacture unless otherwise agreed to in writing.

Individual bit functions are described below. Normally the demodulator channel operates as a synchronous detector to capture complete cycles of a servo burst waveform. However, if CR0 to CR3 are loaded with all 0s, the demodulator channel performs as a simple gated detector stage, gated ON/OFF by the CTRL input. See under CIRCUIT DESCRIPTION—Gated Detector Mode.

CR0 to CR3 determine the number of complete cycles to be synchronously detected within a single burst:

CR3	CR2	CR1	CR0	Cycles
0	0	0	0	Gated Detector
0	0	0	1	NA
0	0	1	0	NA
0	0	1	1	NA
0	1	0	0	4
0	1	0	1	5
0	1	1	0	6
0	1	1	1	7
1	0	0	0	8
1	0	0	1	9
1	0	1	0	10
1	0	1	1	11
1	1	0	0	12
1	1	0	1	13
1	1	1	0	14
1	1	1	1	15

CR4 and CR5 determine the number of bursts which are to be captured.

CR5	CR4	Number of Bursts
0	0	1
0	1	2
1	0	3
1	1	4

CR6 determines whether DAC coding is offset binary or twos complement.

CR6	Coding
0	Offset Binary
1	Twos Complement

CR7, CR8 and CR9 are decoded to provide a number of different functions. CR7 determines whether a signal will be acquired via the synchronous detector's differential inputs or direct from the $C_{INT}(+)$ pin. CR7 is ANDed with the internally generated integrate signal INT to make or break the signal path from the rectifier output to the $C_{INT}(+)$ pin. With CR7 low the rectifier output drives the external integrating capacitor on the C_{INT} pins and all input signals are acquired through the $V_{IN}(+)$ and $V_{IN}(-)$ differential input pins. With CR7 high the synchronous detector stage is bypassed and all input signals are now acquired through the single-ended $C_{INT}(+)$ pin.

CR9	CR8	CR7	Function
0	0	X*	Soft Reset
0	1	X	Power Down
1	0	0	Not Allowed
1	0	1	Calibration Mode
1	1	0	Normal Mode
1	1	1	Not Allowed

*X = don't care.

via software or hardware) the control register is loaded with 364 (Hex) as shown below.

CR0	0
CR1	0
CR2	1
CR3	0
CR4	0
CR5	1
CR6	1
CR7	0
CR8	1
CR9	1

Also on receipt of a reset command the status register is loaded with 3E0 (Hex); i.e., locations SR0–SR4 are loaded with all 0s indicating four good burst captures and conversions complete.

Power Down: In the power down mode all linear circuitry is turned off. Both DAC outputs and the REFOUT output are pulled weakly (5 kΩ) to AGND.

Calibration Mode: The purpose of this mode is to allow any channel mismatch which may exist between the four internal track/hold amplifiers to be easily measured. See under CIRCUIT DESCRIPTION—Calibration Mode section.

Normal Mode: This is the normal operating mode and allows external differential input signals to be acquired and converted. The contents of locations CR0–CR3 determine whether the demodulator channel will be in the synchronous detector mode or gated detector mode.

STATUS REGISTER DESCRIPTION

The status register (SR) is the bottom-most register of the 5-deep register stack. It is 10 bits wide and can be written to or read from. Its function is to provide status information on device operation. Location SR0 acts as a BUSY signal for the demodulator channel. SR0 is set high on the rising edge of the first CTRL pulse in a new burst capture sequence and remains high throughout the complete signal acquisition cycle and the subsequent conversion cycle. When the programmed number of conversions are complete, location SR0 is set low. The number of conversions carried out equals the number of bursts captured. This number is programmable from 1 to 4 via locations CR4 and CR5 of the control register. Up to four bursts can be captured and each of these capture operations has an individual status flag, SR1–SR4, associated with it. A logic low or "good" flag in location SR1, for instance, indicates that burst #1 was captured correctly. Alternatively, a logic high or "bad" flag in location SR1 indicates that a problem occurred while capturing burst #1; i.e., for whatever reason, less than the programmed number of cycles in burst #1 were captured. Locations SR5–SR9 of the status register are reserved and must always be read as logic highs for correct operation of the AD7773 and AD7775.

Primarily intended as a read only location, the status register has very limited write functionality. A write to the status register automatically loads all 1s into locations SR0–SR4 regardless of data present on the data bus. These flag settings represent four bad burst captures and conversions incomplete.

PRELIMINARY TECHNICAL DATA

This information applies to a product under development. Its characteristics and specifications are subject to change without notice. Analog Devices assumes no obligation regarding future manufacture unless otherwise agreed to in writing.

As mentioned previously, locations SR5–SR9 are used for production test purposes and must be written high for correct operation of the AD7773 and AD7775. All write instructions to the status register must load the word 11111XXXXX2. Repeated write instructions to address 11_2 (AD7773) or $011X_2$ (AD7775) are all decoded to the status register.

CIRCUIT DESCRIPTION

The AD7773 and AD7775 are intended primarily for embedded servo head positioning applications in Winchester-type disk drives. The demodulator channel can capture high speed servo data from a variety of embedded servo patterns. Up to four sequential input signals can be captured, converted to digital form and stored in the four data registers ADCREG1–ADCREG4. The 10-bit DAC output can be used to control the head position via a voice coil motor (VCM). The 8-bit DAC output can be used for spindle speed control, gain control, filter control etc. There are two major modes of operation of the demodulator channel—synchronous detector mode and gated detector mode. In the synchronous detector mode the differential input signals are applied in bursts to the differential inputs $V_{IN}(+)$ and $V_{IN}(-)$. A zero crossing detector (ZCD) is used to synchronously detect full cycles of the input signal within a given burst which are then rectified and integrated. Both the number of cycles within an individual burst and also the number of bursts to be captured are programmable. In the gated detector mode the synchronous detector is bypassed and the differential input signals are simply rectified and integrated as long as CTRL remains high. Whether in the synchronous detector mode or in the gated detector mode, a third mode, a calibration or CAL mode, is possible where a reference voltage is connected to the $C_{INT}(+)$ pin to allow any mismatch which exists between the four track/hold (T/H) amplifiers to be easily measured. A simplified diagram of the demodulator channel is shown in Figure 6. With CR7 a logic Low the normal mode is selected and SW1 is closed when a valid integrate INT signal is provided by the demodulator control logic. Switches SW1 and SW3 are functional only in the normal mode. In the calibrate mode CR7 is set to a logic high and SW1 is open regardless of the INT signal. Switch SW2 is closed only in the calibrate mode. The sequence of events in each mode is explained in the following text.

Synchronous Detector Mode

The differential input circuitry is shown in Figure 7. The value of the input capacitors should be chosen so that the pole formed by the capacitor and the 2.5 kΩ equivalent input resistance is at least an order of magnitude below the lowest input signal frequency. These input resistors have a tolerance of ±40% with a typical temperature coefficient of −300 ppm/°C. The differential inputs are biased at approximately 1 V above AGND by means of a low output impedance voltage source.

PRELIMINARY TECHNICAL DATA

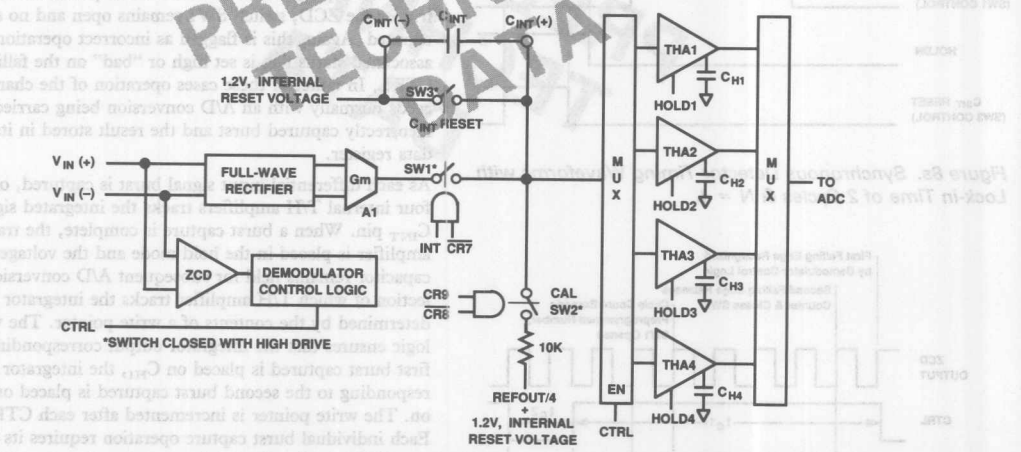

Figure 6. Simplified Block Diagram of Demodulator Channel

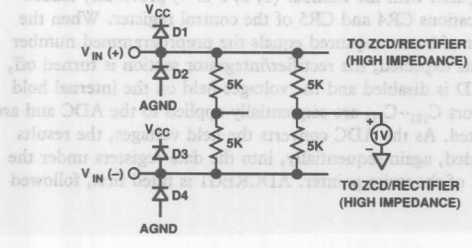

Figure 7. Simplified Input Circuitry of Demodulator Channel

From the input pins the signal passes to both a zero crossing detector (ZCD) and a full wave rectifier. The output of the rectifier drives a transconductance amplifier to convert the rectified input voltage into an output current suitable for charging the external integrating capacitor C_{INT}. Except during actual ADC conversions the ZCD is always enabled and produces a continuous pulse stream output reflecting the differential input signal transitions through 0 V. In fact, the input signal change must exceed the ZCD's input hysteresis, V_H, before its output changes. See Figure 20 in the DESIGN INFORMATION section. Since the ZCD output is usually completely asynchronous

This information applies to a product under development. Its characteristics and specifications are subject to change without notice. Analog Devices assumes no obligation regarding future manufacture unless otherwise agreed to in writing.

with the timing of the CTRL input, the main task of the demodulator control logic is to synchronize these two signals in order to integrate only full cycles of the input waveform. This is achieved by initializing the cycle counter logic on the first ZCD output falling edge recognized after CTRL goes high and releasing the counter on the following ZCD output falling edge. This produces the integrate (INT) signal to close switch SW1 to start integrating. Full cycles of the input waveform can now be counted from falling edge to falling edge of the ZCD output. The asynchronous nature of the two signals results in a random lock-in time before the integrator starts, which can vary from 1 cycle to 2 cycles of the input waveform. This is illustrated in Figures 8a and 8b. CTRL must be high for a minimum time of $(N + 3.5)\ t_{CYC}$; i.e., 7.5 cycles of the maximum burst frequency of 5 MHz when N = 4.

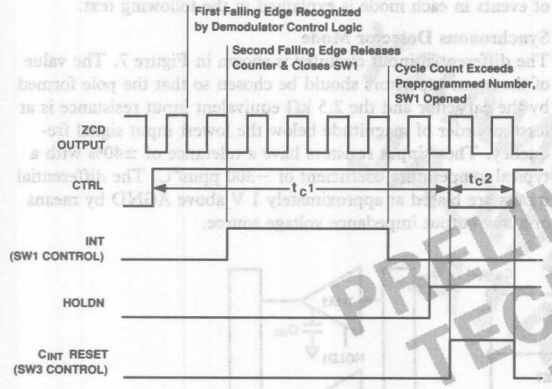

Figure 8a. Synchronous Detector Timing Waveforms with Lock-In Time of 2 Cycles & N = 4.

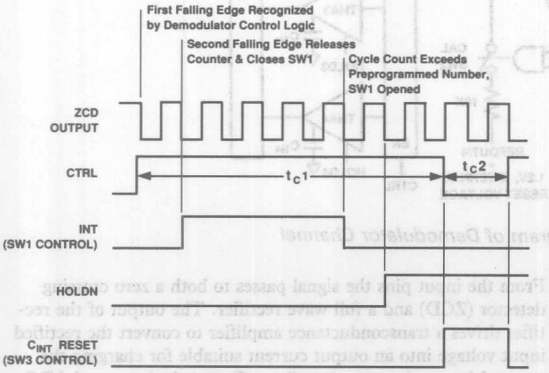

Figure 8b. Synchronous Detector Timing Waveforms with Lock-In Time of 1 Cycle & N = 4.

After the counter is released, the number of subsequent falling edges is counted and is compared with the number previously loaded into locations CR0–CR3 of the control register. When this count exceeds the preprogrammed number, the demodulator control logic brings INT Low, opening switch SW1 to halt the integrator. To ensure that the selected track/hold amplifier correctly acquires the integrated voltage on C_{INT}, a further one full cycle of the ZCD output (i.e., one full cycle of the input waveform) is counted before a hold signal, HOLD1–HOLD4, is generated.

When CTRL returns low, switch SW3 is closed to reset the voltage across the integrating capacitor to 0 V. The waveforms in Figure 8 are drawn for a correct burst capture and the status flag associated with this burst, SR1–SR4, is set "good"—a logic low—in the status register. However, there may be occasions when, for whatever reason, less than the programmed number of cycles occur in a burst, and in these circumstances the trailing edge of CTRL acts as a fail-safe hold signal for the T/H amplifier. For instance if, while capturing a burst, the signal amplitude drops below the minimum ZCD comparator threshold, then the ZCD will obviously cease providing zero-crossing pulses and invalidate the cycle counting logic. In situations like this, the trailing edge of CTRL terminates the integrator directly. If any individual burst capture is terminated by the falling edge of CTRL, then its associated status flag in the status register is set high indicating a "bad" capture. In the situation where an expected burst is so low in amplitude as not even to trigger the ZCD, switch SW1 remains open and no signal is integrated. Again, this is flagged as incorrect operation and its associated status flag is set high or "bad" on the falling edge of CTRL. In either of these cases operation of the channel proceeds normally with an A/D conversion being carried out on the incorrectly captured burst and the result stored in its respective data register.

As each differential input signal burst is captured, one of the four internal T/H amplifiers tracks the integrated signal on the C_{INT} pin. When a burst capture is complete, the tracking T/H amplifier is placed in the hold mode and the voltage on its hold capacitor remains held for subsequent A/D conversion. The selection of which T/H amplifier tracks the integrator output is determined by the contents of a write pointer. The write pointer logic ensures that the integrator output corresponding to the first burst captured is placed on C_{H1}, the integrator output corresponding to the second burst captured is placed on C_{H2} and so on. The write pointer is incremented after each CTRL pulse. Each individual burst capture operation requires its own separate CTRL; pulse, i.e., if there are four bursts to be captured, four CTRL pulses are required. The number of bursts captured is compared with the number (1, 2, 3 or 4) previously loaded into locations CR4 and CR5 of the control register. When the number of bursts captured equals the preprogrammed number of bursts expected, the rectifier/integrator section is turned off, the ZCD is disabled and the voltages held on the internal hold capacitors C_{H1}–C_{H4} are sequentially applied to the ADC and are converted. As the ADC converts the held voltages, the results are loaded, again sequentially, into the data registers under the control of the write pointer. ADCREG1 is filled first, followed

This information applies to a product under development. Its characteristics and specifications are subject to change without notice. Analog Devices assumes no obligation regarding future manufacture unless otherwise agreed to in writing.

by ADCREG2, etc. When all held voltages have been converted, the T/H amplifiers are released back into their track mode and the write pointer is left pointing at T/H amplifier #1. At this time also, the ZCD is again enabled. Note, however, that the 4-channel T/H multiplexer is enabled on the rising edge of the first CTRL pulse in a new burst capture sequence and remains enabled only for the duration of the capture sequence.

Gated Detector Mode

In this mode the synchronous detector is bypassed and the demodulator channel behaves as a simple gated detector. To select the gated detector mode, locations CR0–CR3 of the control register are loaded with all 0s, location CR7 is loaded with a logic low and locations CR8 and CR9 are loaded with logic highs. A simplified timing diagram of the channel operating as a gated detector is shown in Figure 9. When CTRL goes high at the start of a signal capture operation, switch SW1 is closed and the integrator starts integrating the rectifier's output. It will continue to do so as long as CTRL remains high, eventually saturating if CTRL is held high for too long. A minimum CTRL high pulse width of 800 ns is required in this mode. When CTRL returns low, switch SW1 is opened and the integrator is halted. As the rectifier's output is being integrated across C_{INT}, it is also being tracked by one of the four T/H amplifiers. To provide additional time for this T/H amplifier to completely acquire the integrated voltage, the falling edge of CTRL triggers a one-shot which delays the hold signal, HOLD1–HOLD4, until it times out. This delay, t_C3, has a maximum time of 600 ns. When the hold signal is generated the tracking T/H amplifier is put in the hold mode and the voltage on its hold capacitor remains held for subsequent A/D conversion. The hold signal, in turn, triggers the C_{INT} reset signal, closing SW3 and resetting the voltage across C_{INT} to 0 V. Note that both plates of the C_{INT} capacitor are at the internal reset voltage level of 1.2 V, available on $C_{INT}(-)$, in readiness for the next signal capture operation. The minimum CTRL low time, t_C2, depends on the duration of the preceding CTRL high time. The longer the integration time, the longer must be the reset time, since the reset current is fixed. The minimum CTRL low time can be determined from the expression:

$$t_C2 = 0.6\ \mu s + 0.375\ t_C1$$

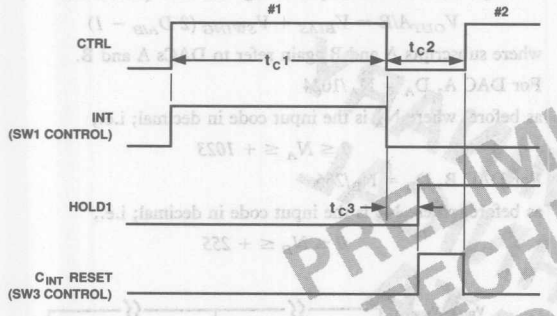

Figure 9. Channel Timing Waveforms for Gated Detector Mode

When the number of gated signals captured equals the preprogrammed number expected, the rectifier/integrator section is disabled and the held voltages are sequentially applied to the ADC and are converted. From here on, channel operation is identical to the synchronous detector mode as previously described. Note that locations SR1–SR4 of the status register now convey no meaningful information and should be ignored for gated detector operation.

Calibration Mode

The purpose of this mode is to allow any channel mismatch existing between the internal T/H amplifiers to be easily measured. The number of T/H amplifiers tested will equal the number stored in locations CR4 and CR5 of the control register. Additionally the number of CTRL pulses applied must also equal this number. The calibration (CAL) mode is selected by loading locations CR9 and CR8 of the control register with a logic high and a logic low, respectively. This condition is decoded to close switch SW2 and connect an internal dc reference, nominally REFOUT/4 above the $C_{INT}(-)$ pin, to the $C_{INT}(+)$ pin. Additionally, to avoid shorting the integrator output, switch SW1 must be opened by loading a logic high into location CR7. Unlike either the synchronous or gated detector modes, the voltage on C_{INT} is not discharged between successive CTRL pulses. In this mode the CTRL pulses simply generate the hold signals for the T/H amplifiers. The falling edge of the first CTRL pulse generates a hold signal, HOLD1, for T/H amplifier #1, the falling edge of the second CTRL pulse generates HOLD2 for T/H amplifier #2, and so on. A timing diagram of the channel in the CAL mode is shown in Figure 10.

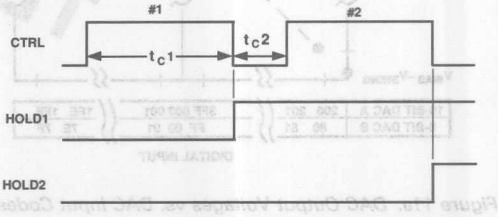

Figure 10. Channel Timing Waveforms for Calibration Mode

A minimum CTRL pulse width of 800 ns is required to allow sufficient acquisition time for the relevant T/H amplifier. Note that this pulse width assumes that the voltage on the $C_{INT}(+)$ pin has settled to the nominal REFOUT/2 level before the first CTRL pulse is applied. In order to use the minimum CTRL pulse widths the demodulator channel must be placed in the calibration mode some time prior to applying the first CTRL pulse. With C_{INT} = 180 pF, this setup time is no longer than 20 μs. Alternatively, this setup time can be avoided by making the first CTRL pulse sufficiently wide to ensure that the calibration voltage on the $C_{INT}(+)$ pin has settled. Subsequent CTRL pulses can obviously have minimum pulse widths.

8

PRELIMINARY TECHNICAL DATA

This information applies to a product under development. Its characteristics and specifications are subject to change without notice. Analog Devices assumes no obligation regarding future manufacture unless otherwise agreed to in writing.

The AD7773 and AD7775 contain two independent voltage-output DACs: DAC A with 10-bit resolution and DAC B with 8-bit resolution. The two DACs produce output voltages of the form $V_{BIAS} \pm V_{SWING}$. Both V_{BIAS} and V_{SWING} reference levels are generated internally with V_{BIAS} being available externally on the REFOUT pin. V_{SWING} is nominally equal to REFOUT/2. With half-scale code in a DAC register, the DAC output voltage is equal to V_{BIAS}; With a positive full-scale code the DAC output is $V_{BIAS} + V_{SWING} - 1$ LSB; with a negative full-scale code the DAC output is $V_{BIAS} - V_{SWING}$. Dependent upon the logic level stored in location CR6 of the control register, the DAC coding (for both DACs) will be either twos complement coding (CR6 = 1) or offset binary coding (CR6 = 0). Note that on receipt of a reset command (either via software or hardware), location CR6 is loaded with a logic high and the analog outputs of both DACs go to V_{BIAS}. Figures 11a and 11b show the DAC transfer functions for twos complement and offset binary coding, respectively.

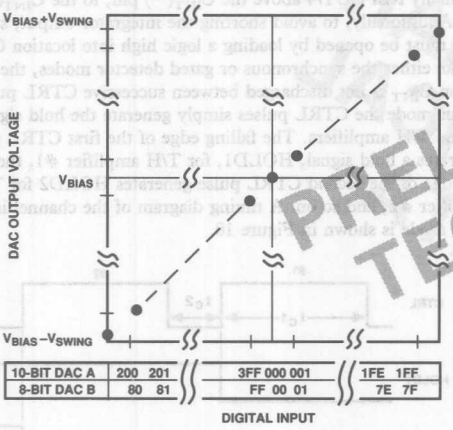

Figure 11a. DAC Output Voltages vs. DAC Input Codes in Hex—Two's Complement Coding

expressed as:

$$V_{OUT}A/B = V_{BIAS} + V_{SWING}(2\ D_{A/B})$$

where subscripts A and B refer to DACs A and B.

For DAC A, $D_A = N_A/1024$

where N_A is the decimal equivalent of the twos complement input code; i.e.,

$$-512 \le N_A \le +511$$

For DAC B, $D_B = N_B/256$

where N_B is the decimal equivalent of the twos complement input code; i.e.,

$$-128 \le N_B \le +127$$

With offset binary coding selected via location CR6 of the control register, the DAC output voltage can be expressed as:

$$V_{OUT}A/B = V_{BIAS} + V_{SWING}(2\ D_{A/B} - 1)$$

where subscripts A and B again refer to DACs A and B.

For DAC A, $D_A = N_A/1024$

as before, where N_A is the input code in decimal; i.e.,

$$0 \le N_A \le +1023$$

For DAC B, $D_B = N_B/256$

as before, where N_B is the input code in decimal; i.e.,

$$0 \le N_B \le +255$$

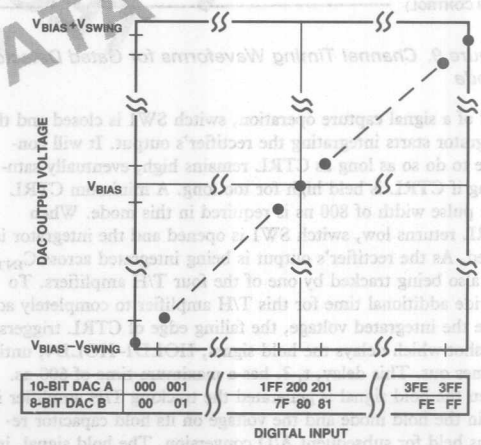

Figure 11b. DAC Output Voltages vs. DAC Input Codes in Hex—Offset Binary Coding

PRELIMINARY TECHNICAL DATA

MICROPROCESSOR INTERFACING

Tables I and II show the truth tables for AD7773 and AD7775 microprocessor interfacing, respectively. The multiplexed address/data bus used by the AD7775 is demultiplexed internally by means of the ALE signal. On the falling edge of ALE address inputs AD1, AD2 and AD3 are latched and remain latched until ALE returns high again. Note that address input AD0 is a "don't care" input. This decoding scheme allows 2-byte word operations to even addresses only and simplifies the interface to the 80C196, for instance, where word operations to odd addresses are not guaranteed to operate in a consistent manner. DAC data is always transferred as right-justified data, i.e., the LSB should always appear on AD0 whether loading the 10-bit DAC A or 8-bit DAC B. Similarly for the AD7773, which has a dedicated 10-bit-wide data bus, DAC data is always transferred as right-justified data, i.e., the LSB should always appear on DB0 whether loading DAC A or DAC B.

Table I. AD7773 Truth Table for Microprocessor Interfacing

PRELIMINARY TECHNICAL DATA

8

This information applies to a product under development. Its characteristics and specifications are subject to change without notice. Analog Devices assumes no obligation regarding future manufacture unless otherwise agreed to in writing.

Stack Reading

The register stack consists of a total of five registers: the status register and the four ADC data registers, ADCREG1–ADCREG4. The status register is the bottom-most register of the 5-deep register stack. Dependent upon the system architecture, the stack can be read in one of two ways. If the AD7773 and AD7775 are interfaced directly to a microprocessor bus then repeated read instructions to the stack address rotate the active stack locations through the data bus. One stack location is transferred per read instruction. This method of stack reading is shown in Figure 12a for the AD7773 (stack address = 11_2) and in Figure 13a for the AD7775 (stack address = $011X_2$). However, if the AD7773 or AD7775 is not directly interfaced to the microprocessor bus but comes through some peripheral controller (e.g., a proprietary gate array), then the stack can be rotated by keeping the $\overline{CS}$ input low and repeatedly pulsing the $\overline{RD}$ input. This method of stack reading is shown in Figures 12b and 13b for the AD7773 and AD7775, respectively.

For the AD7773, stack rotation is the only way in which data in the upper registers can be accessed. For the AD7775, however, the stack registers are individually addressable and the user can choose to access the data by rotating the stack, or by individually addressing the registers in any order preferred.

A read pointer ensures correct operation of the stack by setting equal the number of data registers which can be rotated and the number of bursts to be captured. The first read instruction to the register stack returns the contents of the status register. The read pointer is then incremented so that the next read operation from the stack—using the same address—returns the conversion data from ADCREG1 and so on. If n is the number of bursts to be captured (n = 1, 2, 3 or 4), then n + 1 read instructions are required to rotate the stack through all active stack registers. The stack is rotated only once with all additional read instructions repeatedly placing the contents of the status register on the data bus. Note that the stack will rotate only when the programmed number of conversions are complete; i.e., only when status register flag SR0 has returned low. When new data is loaded to the stack, for example, when a new burst sequence is captured, the read pointer is again enabled to rotate the stack registers through the data bus. Operation of the stack is summarized in Table III where all the read instructions are from stack addresses; 11_2 for the AD7773 and $011X_2$ for the AD7775.

Table III. Stack Read Operations

Read Instruction Sequence	Data Bus
1st Read	Status Register
2nd Read	ADCREG1
3rd Read	Status Register if CR (5, 4) = (0, 0); ADCREG2 otherwise
4th Read	Status Register if CR (5, 4) = (0, 0) or (0, 1); ADCREG3 otherwise
5th Read	Status Register if CR (5, 4) = (0, 0), (0, 1) or (1, 0); ADCREG4 otherwise
6th Read	Status Register. Succeeding Read instructions always call the Status Register

PRELIMINARY TECHNICAL DATA

This information applies to a product under development. Its characteristics and specifications are subject to change without notice. Analog Devices assumes no obligation regarding future manufacture unless otherwise agreed to in writing.

Microprocessor/Microcomputer Interfacing Circuits

With its separate data and address bus architecture the AD7773 is intended to interface to DSP machines such as the ADSP-2101, ADSP-2105 and the TMS320 family. The AD7775, with its multiplexed address/data bus, is suitable for microcontrollers such as the 80C196 family.

Figure 14 shows the AD7773 interfaced to the TMS320C10 @ 20.5 MHz and the TMS320C14 @ 25 MHz. Figure 15 shows the interface with the TMS320C25 @ 40 MHz. Note that one wait state is required with this interface. The ADSP-2101-50 and the ADSP-2105-40 interface is shown in Figure 16. One wait state is required with either of these machines.

Figure 17 shows the AD7775 interface to the 80C196KB @ 12 MHz and the 80C196KC @ 16 MHz. One wait state is required with the 16 MHz machine. The 80C196 is configured to operate with a 16-bit multiplexed address/data bus.

DEMODULATOR CHANNEL

Relative Accuracy

The relative accuracy specification is similar to a least squares specification for a standard ADC. For the demodulator channel, however, the least squares line is fitted not between the voltage levels corresponding to the traditional first and last code transitions, but between voltage levels corresponding to designated code transitions on either side of the midscale code. This scheme allows a tighter specification for signals around the half-scale point and a more relaxed specification for signals closer to zero-scale and full-scale. The AD7773/AD7775 specify linearity over the 1/4 FS to 3/4 FS signal range with a related linearity specification from 1/8 FS to 7/8 FS. For either range the input signal levels that correspond to the designated code transitions are found by applying a sequence of 5 MHz sinusoidal bursts to the demodulator channel and digitizing the signals. The amplitude of the bursts are slowly varied until the ADC output flickers around the nominated code transition. The burst amplitude which causes the transition is now designated as one endpoint for the linearity specification. The other endpoint (for the same range) is found by similar methods. The 1/4 FS to 3/4 FS relative accuracy specification of the demodulator channel is the maximum deviation, in LSBs, of the ADC's actual code transition points from a least squares line fitted between the measured endpoint voltages Vm256 and Vm768. Note that this least squares line may not exactly coincide with a straight line drawn between the two measured endpoint voltages. The 1/8 FS to 7/8 FS relative accuracy specification is referred to the least squares line already fitted between 1/4 FS and 3/4 FS but which is now extended to range from Vm128 to Vm896. A graphical representation of the two linearity ranges are shown in Figure 18 where ADC code transitions (in decimal only) are plotted versus their corresponding input voltage levels; i.e., Vm128 represents the input voltage at which code transition 127/128 (decimal) occurs. Corresponding code transitions in Hex are as follows:

Vm128: 07F/ 080 (Hex)
Vm256: 0FF/100 (Hex)
Vm768: 2FF/300 (Hex)
Vm896: 37F/380 (Hex)

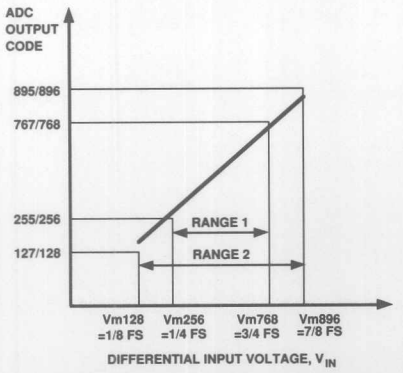

Figure 18. Guaranteed Linearity Ranges for the Demodulator Channel

The full-scale (FS) input voltage is computed from measured voltages Vm128 and Vm896, corresponding to 1/8 FS and 7/8 FS, respectively, as follows:

$$Vm896 - Vm128 = 7/8FS - 1/8\ FS$$

or

$$FS = 8/6\ (Vm896 - Vm128)$$

Using this value of FS, 1 LSB = FS/1024. Note that due to both the zero-crossing detector threshold and the rectifier threshold, the least squares line shown in Figure 18 will not pass through the origin. This means that the differential input voltages shown in Figure 18 are not referenced to the origin; i.e., the code transition 127/128 does not necessarily occur 1/8 FS above V_{IN} = 0 V.

Differential Input Resistance

This is the dc input resistance measured between $V_{IN}(+)$ and $V_{IN}(-)$.

Common-Mode Input Resistance

This is the dc input resistance measured between the shorted differential inputs, $V_{IN}(+)$ and $V_{IN}(-)$, and ground.

ADC Code for 75 mV Differential Input Signal

For the guaranteed minimum differential input signal of 75 mV p–p the resultant output code will be between 0A (Hex) and 28 (Hex), which is between 10 LSBs and 40 LSBs. Figure 6 shows the typical demodulator performance for low level input signals. The minimum differential input signal is determined by the rectifier threshold. Above the rectifier threshold the ADC output is guaranteed to be monotonic up to the maximum differential signal of 2.3 V p–p.

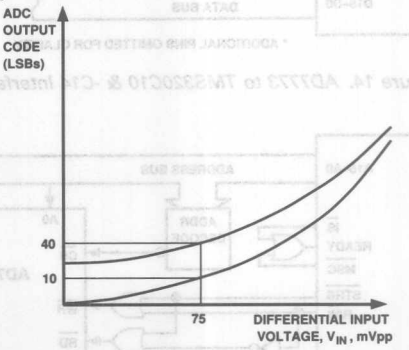

Figure 19. Demodulator Response for Low Level Input Signals

Frequency Response to Pulse Harmonics

This specification tests for gain peaking in the channel frequency response. Relative measurements, taken at three harmonically related frequencies, are compared and must be within specification. To maintain a constant integral at each frequency, the number of cycles are correspondingly increased as the signal period is decreased.

–Set up 5 MHz bursts at 0.7 V p–p and digitize. CR0–CR3 set for 4 cycles. Determine average ADC code, call it Code 1.

This information applies to a product under development. Its characteristics and specifications are subject to change without notice. Analog Devices assumes no obligation regarding future manufacture unless otherwise agreed to in writing.

–Set up 10 MHz bursts at 0.7 V p–p and digitize. CR0–CR3 set for 8 cycles. Determine average ADC code, call it Code 2.

–Set up 15 MHz bursts at 0.7 V p–p and digitize. CR0–CR3 set for 12 cycles. Determine average ADC code, call it Code 3.

–Compare (Code 1–Code 2) and (Code 1–Code 3) to the limits specified.

Due to the demodulation technique used in the AD7773 and AD7775, the frequency spectrum of the input signal can have an impact on the demodulator channel performance. To meet the specifications the following limits are placed on the harmonic content of the input signal (quoted in dB relative to a fundamental at 5 MHz and 1.25 V p–p):

2nd Harmonic:	−50 dB
3rd Harmonic:	−12 dB
4th Harmonic:	−50 dB
5th Harmonic:	−24 dB
Higher Harmonics:	−40 dB total

Common-Mode Rejection Ratio

Common-mode rejection ratio (CMRR) is a measure of the change in digital output code when both inputs are changed by equal amounts. Repeated bursts of half-scale amplitude, differential 1.25 V p–p at 5 MHz, are applied to the demodulator channel and digitized. These bursts sit on a common-mode signal of 500 mV p–p magnitude and varying in frequency from 60 Hz to 30 kHz. The standard deviation of the resultant distribution of ADC codes is checked to be less than 3.1 LSBs, a result which includes the channel noise level. When corrected for the channel noise level by rms subtraction, e.g., $\{(3.1)^2 - (1.8)^2\}^{1/2}$, the standard deviation is found to be less than 2.5 LSBs, which is equivalent to a CMRR of 46 dB. This specification holds over the allowable V_{CC} range of 4.75 V to 5.25 V.

Power Supply Rejection Ratio

For the demodulator channel, power supply rejection ratio (PSRR) is a measure of the change in digital output code due to a change in the power supply voltage. Repeated bursts of half-scale amplitude, differential 1.25 V p–p at 5 MHz, are applied to the input and digitized. An ac signal, 200 mV p–p amplitude and varying in frequency from 60 Hz to 30 kHz, is summed with the +5 V power supply V_{CC}. The standard deviation of the resultant distribution of ADC codes is checked to be less than 4 LSBs, a result which includes the channel noise level. When corrected for the channel noise level by rms subtraction, e.g., $\{(4)^2 - (1.8)^2\}^{1/2}$, the standard deviation is found to be less than 3.6 LSBs, which is equivalent to a PSRR of 43 dB. This specification holds over the allowable V_{CC} range of 4.75 V to 5.25 V.

Channel Noise Level

Channel noise level is a measure of the intrinsic noise level of the modulator channel in the absence of common-mode signals and power supply interference. Repeated bursts of half-scale amplitude, differential 1.25 V p–p at 5 MHz, are applied to the input and digitized. The standard deviation of the resultant distribution of ADC codes is checked to be less than 1.8 LSBs. This is equivalent to a channel noise level of 49 dB. Note that the duration of the burst capture sequence must be less than or equal to 1 ms.

Composite Noise Rejection

Intended as an overall channel performance indicator, the composite noise rejection figure is an rms summation of the PSRR, CMRR, the channel noise level as defined above plus an INL error of 1.15 LSBs, representing the standard deviation, under identical test conditions, of the ADC codes from device to device. It is referenced to half-scale.

Channel Mismatch

Channel mismatch is a measure of the differences which may exist between the four internal track/hold (T/H) amplifiers. To measure mismatch the AD7773/AD7775 must be put in the calibration (CAL) mode by loading control register locations CR9 and CR8 with a logic high and a logic low, respectively. Additionally, CR7 must be loaded with a logic high. These conditions disconnect the output of the integrator from the integrating capacitor C_{INT} and connect an internal dc reference (Nominally REFOUT/4 above the voltage on the $C_{INT}(-)$ pin) to the $C_{INT}(+)$ pin. The remainder of the demodulator channel operates normally: under the control of the CTRL input, the four T/H amplifiers are connected in turn to track-and-hold this reference voltage. Subsequently the held voltages are converted. Check the ADC output code for each channel to ensure results are within 5 LSBs of each other. See under CIRCUIT DESCRIPTION for Calibration Mode section.

Crosstalk Between Bursts

Between successive bursts the integrating capacitor C_{INT} is discharged to 0 V. This occurs during time t_C2 of Figures 8a, 8b and 9. Note that both plates of the C_{INT} capacitor are at the internal reset voltage level of 1.2 V, available on $C_{INT}(-)$. Any residual signal on this capacitor will be added to the integrated signal of the succeeding burst causing an apparent increase in the amplitude of that burst. The crosstalk specification defines by how much the amplitude of a burst is influenced by a preceding burst. By this definition the first burst suffers no crosstalk, the second burst suffers from the first burst, etc. To measure crosstalk a special burst sequence is applied to the demodulator input which keeps the amplitude of the burst under test constant at half-scale (differential 1.25 V p–p at 5 MHz) and alternates the amplitude of the preceding burst between 0 V and full scale. The average error due to crosstalk should be less than 1 LSB. Only two successive bursts are exercised in any one sequence.

ADC Conversion Time

Each conversion takes 14 CLKIN cycles. However, due to the asynchronous relationship between CLKIN and the burst detector operation, it is possible to get a delay of up to 2.5 CLKIN cycles before the first conversion actually starts. This means that the first conversion may not be finished for up to 14 + 2.5 CLKIN cycles after the final burst has been detected. Subsequent conversions will always take 14 CLKIN cycles.

ANALOG OUTPUTS

Relative Accuracy

For the DACs, relative accuracy or end-point nonlinearity is a measure of the maximum deviation, in LSBs, from a straight line passing through the endpoints of the DAC transfer function. A graphical representation of the transfer curves for both twos complement and offset binary coding are shown in Figures 11a and 11b, respectively.

Differential Nonlinearity

Differential nonlinearity is the difference between the measured change and the ideal 1 LSB change between any two adjacent codes. A specified differential nonlinearity of ±1 LSB maximum ensures monotonicity.

Bias Offset Error

If the DACs are ideal, the output voltage of any DAC with midscale code loaded will be equal to V_{BIAS} (i.e., REFOUT). The DAC bias offset error is the difference between the actual output voltage and V_{BIAS}, expressed in LSBs.

Plus and Minus Full-Scale Error

The DACs in the AD7773/AD7775 can be considered to provide bipolar output voltage ranges which are referred to V_{BIAS} instead of AGND. Plus full-scale error for any DAC is the difference, expressed in LSBs, between the actual output voltage with plus full-scale code loaded into the DAC register and the ideal output voltage (V_{BIAS} + V_{SWING} − 1 LSB). Minus full-scale error is similarly defined but the DACs are now loaded with their minus full-scale codes and the ideal output voltage is now V_{BIAS} − V_{SWING}. Note that plus and minus full-scale errors for the DAC outputs are referenced to REFOUT/2 and are measured after the bias offset errors have been adjusted out.

Digital-to-Analog Glitch Impulse

Digital-to-analog glitch impulse is the impulse injected into the analog output when the digital inputs change state with the DAC selected. It is normally specified as the area of the glitch in nV secs and is measured when the digital input code is changed by 1 LSB at the major carry transition. Regardless of whether offset binary or 2s complement coding is used, the major carry transition occurs at the analog output voltage change of V_{BIAS} to V_{BIAS} − 1 LSB or vice versa.

Digital Feedthrough

Digital feedthrough is also a measure of the impulse injected into the analog output from the digital inputs but is measured when the DAC is not selected. It is essentially feedthrough across the die and package. It is important in the AD7773/AD7775 since it is a measure of the glitch impulse transferred to the analog output when data is transferred over the data bus (either in or out). It is specified in nV secs and is measured with a full-scale code change on the data bus, from all 0s to all 1s and vice versa.

Power Supply Rejection Ratio

For the analog outputs, power supply rejection ratio (PSRR) is a measure of the change in the analog output of either DAC due to a change in the power supply voltage V_{CC}. For the test both DACs are loaded with their half-scale codes and an ac signal of 200 mV p–p amplitude and varying in frequency from 60 Hz to 30 kHz is summed with the +5 V power supply. The maximum output signal level on either DAC will be 22 mV. Thus, the response will be at least 20 dB below the excitation level. This specification holds over the allowable V_{CC} range of 4.75 V to 5.25 V.

DESIGN INFORMATION

Choosing the C_{INT} Capacitor

In both the synchronous detector and gated detector modes the differential input signal is rectified and integrated across the integrating capacitor C_{INT}. The correct value of integrating capacitor must be used in order to optimize the channel performance for any particular integration period. If too high a value is chosen then the integrated signal voltage developed across C_{INT} will be lower than optimum, and hence, ADC resolution will be lost due to this effective compression of the signal. Similarly too low a value for C_{INT} can lead to signal voltages being developed across C_{INT} which are beyond the dynamic range of the ADC. This effective signal expansion results in loss of ADC resolution for full-scale input signals. The ideal value of C_{INT} is found from the expression:

$$C_{INT} = I.T/V_{C_{INT}} \quad \ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots (1)$$

where I is the average rectifier output current, T is the integrate time and V_{CINT} is the integrated voltage across C_{INT}. The average rectifier output current can be expressed as:

$$I = Gm.V_{IN}\ (average)$$
$$= Gm.V_{IN}\ peak.\ (Crest\ Factor)$$
$$= Gm\ (V_{IN}\ p\text{–}p/2)\ (Crest\ Factor)$$

For sinusoidal burst signals the crest factor is equal to $2/\pi$.

In the synchronous detector mode the integrate time can be expressed as:

$$T = t_{INTEGRATE}$$
$$= N.t_{CYC}$$
$$= N/f_{IN}$$

where N is the number programmed into locations CR0–CR3 of the control register. N can range from 4 to 15. Frequency f_{IN} is the frequency of the input signal. The AD7773 and AD7775 are guaranteed to operate with N = 4 and f_{IN} = 5 MHz maximum. In the gated detector mode the integrate time is simply the period of CTRL high or t_{C1} in Figure 9.

V_{CINT} is the voltage change across C_{INT} which results in a full-scale change in the ADC output. V_{CINT} is typically equal to REFOUT/2 or 1.07 V.

As an example of calculating a value for C_{INT} consider the case of synchronous detector operation with N = 4, f_{IN} = sinusoidal 5 MHz and V_{IN} p–p = 2.3 V maximum. To ensure that no ADC resolution is lost for peak input signals, Equation 1 is solved using the maximum value of transconductance, Gm = 0.302 ms and the minimum value of V_{CINT} which is equal to REFOUT(min)/2 or 1.05 V. When these values are used in Equation 1 a value for C_{INT} equal to 170.7 pF is computed. This computed value of capacitor must include the tolerance, Δ, on the final capacitor chosen plus any stray capacitance on the C_{INT}(+) pin to ground and C_{INT}(−). That is,

$$170.7\ pF = C_{INT}\ (1 - \Delta\%/100) + C_{STRAY}$$

PRELIMINARY TECHNICAL DATA

This information applies to a product under development. Its characteristics and specifications are subject to change without notice. Analog Devices assumes no obligation regarding future manufacture unless otherwise agreed to in writing.

If 5% tolerance capacitors are used and C_{STRAY} = 10 pF then C_{INT} = 169 pF ±5%. This is the optimum value of capacitor to use. However, if preferred values of capacitors are required, the next highest preferred value is 180 pF. This value of capacitor will result in a slight compression of the signal range. That is, a full-scale input signal, V_{IN} p–p = 2.3 V, will result in an ADC code which is less than all 1s. Exactly how much compression is caused by using a nonideal value of C_{INT} is indicated by the ratio of computed C_{INT} value to worst case C_{INT} value. Assuming C_{INT} = 180 pF ±5% and stray capacitance totalling 10 pF, the worst case C_{INT} capacitance can be found by solving

$$C_{INT} = 180\ (1 + 5/100)\ pF + 10\ pF$$
$$= 199\ pF$$

The ratio of 170.7 pF, the computed value for C_{INT}, to 199 pF gives the amount of compression, 170.7/190 = 0.85. This means that for a full-scale input signal the ADC code will never exceed 85% of its possible code range; therefore, approximately the top 150 codes will never be used.

Zero Crossing Detector

The zero crossing detector (ZCD) has a certain amount of hysteresis to prevent noise from getting through the input stage. The ZCD differential hysteresis, V_H, is typically 55 mV p–p and is specified to lie between 40 and 70 mV p–p. Only signals which exceed this level can change the ZCD's output. A 55 mV hysteresis represents approximately 5% of a typical 1.1 V differential input signal level to the demodulator channel. Figure 20 gives a graphical representation of the ZCD sensitivity and hysteresis.

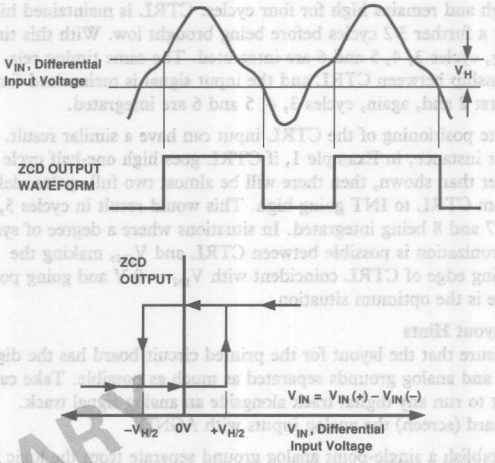

Figure 20. Zero Crossing Detector (ZCD) Sensitivity

Synchronous Detector Timing Relationships

The relative timing between an input burst signal and its respective CTRL pulse determines which of the cycles within an individual burst are integrated. Two different timing examples which result in different cycles of the input waveform being integrated are shown in Figure 21. This is drawn for a two-burst pattern with N, the programmed number of cycles to be captured, set to 4.

In Example 1, the CTRL input goes high just after the rising edge of the ZCD output which itself occurs in the middle of the second cycle of burst 1. Approximately 3/2 cycles after this, the integrate (INT) signal goes high to start the integrator and remains high for four cycles of the input waveform. The CTRL input is maintained high for a further 2 cycles of the input waveform. With this timing relationship, cycles 4, 5, 6 and 7 of burst 1 are integrated. Since CTRL is kept low for the minimum time of 3/2 cycles of the captured input waveform, the same timing relationship between CTRL and the input signal is maintained for burst 2 and, again, cycles 4, 5, 6 and 7 are integrated.

In Example 2, the CTRL input goes high just after the falling edge of the ZCD output at the start of the first cycle of burst 1.

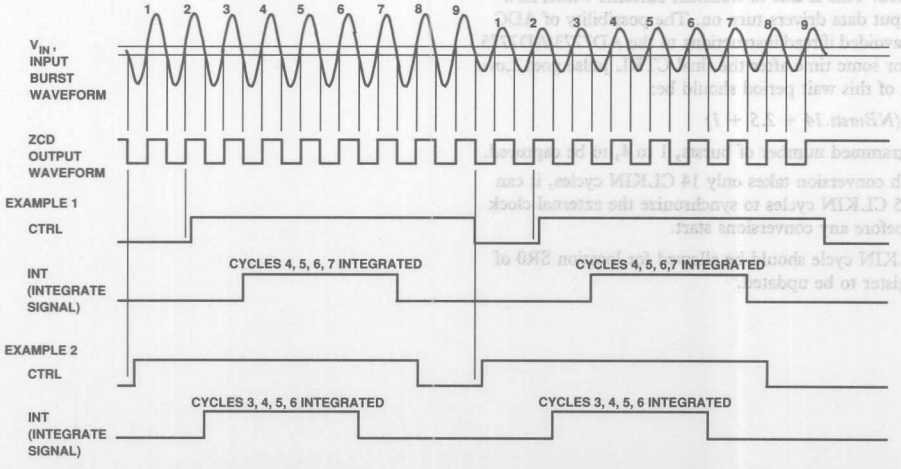

Figure 21. Two Examples of Movement of the Integration Window as a Result of Relative Timing Between CTRL and the Input Burst Signal

This information applies to a product under development. Its characteristics and specifications are subject to change without notice. Analog Devices assumes no obligation regarding future manufacture unless otherwise agreed to in writing.

Approximately 2 cycles later the integrate signal, INT, goes high and remains high for four cycles. CTRL is maintained high for a further 3/2 cycles before being brought low. With this timing, cycles 3, 4, 5 and 6 are integrated. The same timing relationship between CTRL and the input signal is maintained for burst 2 and, again, cycles 3, 4, 5 and 6 are integrated.

Late positioning of the CTRL input can have a similar result. For instance, in Example 1, if CTRL goes high one-half cycle later than shown, then there will be almost two full cycles, delay from CTRL to INT going high. This would result in cycles 5, 6, 7 and 8 being integrated. In situations where a degree of synchronization is possible between CTRL and V_{IN}, making the rising edge of CTRL coincident with V_{IN} = 0 V and going positive is the optimum situation.

Layout Hints

Ensure that the layout for the printed circuit board has the digital and analog grounds separated as much as possible. Take care not to run any digital track alongside an analog signal track. Guard (screen) the analog inputs with AGND.

Establish a single-point analog ground separate from the logic system ground and as close as possible to the AD7773 or AD7775. Both AGND pins on the AD7773/AD7775 and all other signal grounds should be connected to this single-point analog ground. In turn, this star ground should be connected to the digital ground at one point only—preferably at the low impedance power supply itself.

Low impedance analog and digital power supply common returns are important for correct operation of the devices, so make the foil width for these tracks as wide as possible.

In order to ensure a low impedance +5 V power supply at the actual V_{CC} pin, it will be necessary to employ bypass capacitors from the pin itself to DGND. A 4.7 μF tantalum capacitor in parallel with a 0.1 μF ceramic capacitor is sufficient.

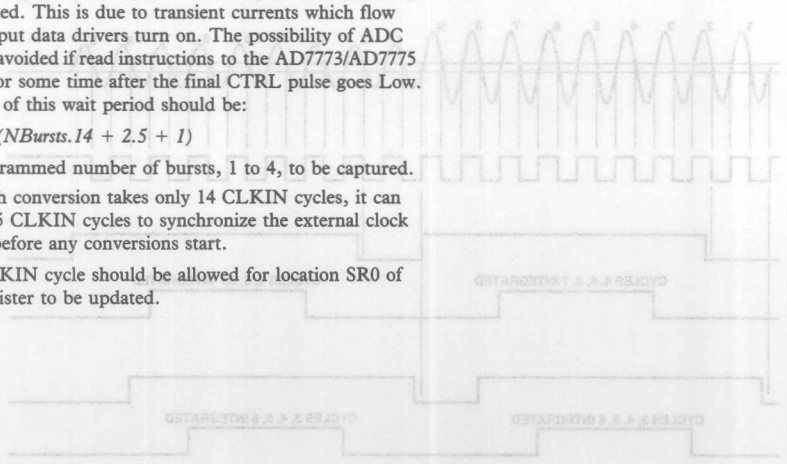
ADC Corruption

Executing a read instruction to the AD7773/AD7775 while conversions are in progress can result in the conversion-in-progress being corrupted. This is due to transient currents which flow when the output data drivers turn on. The possibility of ADC corruption is avoided if read instructions to the AD7773/AD7775 are avoided for some time after the final CTRL pulse goes Low. The duration of this wait period should be:

$$T_{CLKIN}\ (NBursts.14 + 2.5 + 1)$$

N is the programmed number of bursts, 1 to 4, to be captured.

Although each conversion takes only 14 CLKIN cycles, it can take up to 2.5 CLKIN cycles to synchronize the external clock with CTRL before any conversions start.



A further CLKIN cycle should be allowed for location SR0 of the status register to be updated.

Changing Modes of Operation

The AD7773 and AD7775 have two normal operating modes—synchronous detector and gated detector modes – and one calibration mode. Changing between any of these modes simply requires changing the appropriate contents of the control register as already described under the individual descriptions of these modes. However, there are a number of considerations which should be followed when changing between modes. The first is that no mode change be attempted before the burst capture and conversion sequence is complete (i.e., not until location SR0 of the Status Register returns low). This will avoid any inadvertent corruption of a conversion in progress. The second consideration involves the delay between writing to the control register and starting a new burst capture sequence. This time is defined under the Demodulator Timing Characteristics as the $\overline{WR}$ rising edge to CTRL rising edge and is specified as 200 ns minimum. It is required to ensure that the correct conditions have been set up internal to the device.

A final consideration involves allowing sufficient time for the integrating capacitor, C_{INT}, to discharge when changing from the calibration mode to one of the other operating modes. This is necessary since, in this mode, C_{INT} is not discharged by the internal discharge switch, SW3, either between successive CTRL pulses or even on completion of the burst capture sequence. A discharge time of 300 ns—equivalent to t_c2, the CTRL low time in the calibration mode—is adequate after transferring out of the calibration mode. This discharge time and the previous set up time of 200 ns must be added together to arrive at a final overall delay.

PRELIMINARY TECHNICAL DATA

This information applies to a product under development. Its characteristics and specifications are subject to change without notice. Analog Devices assumes no obligation regarding future manufacture unless otherwise agreed to in writing.

LC²MOS Analog I/O Port

AD7774

FEATURES
Four-Channel, 8-Bit, 3.6 µs ADC
Three DACs with On-Chip Amplifiers:
One 11-Bit, 8 µs DAC
Two 8-Bit, 4 µs DACs
Simultaneous/Independent Sampling of Input Channels
Adjustable Span and Bias Voltage for Input Channels
Adjustable Bias Voltage for Output Channels
Operates from +5 V and +12 V Supplies

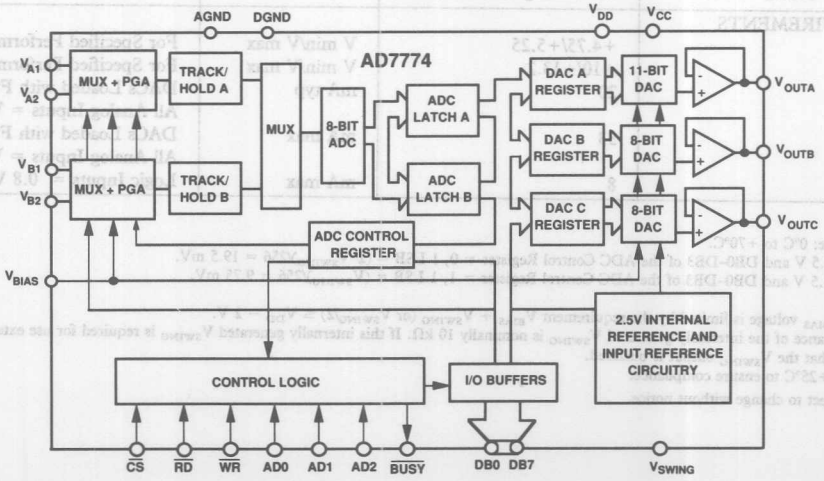
APPLICATIONS
HDD Dedicated Servo
HDD Hybrid Servo
Closed-Loop Servo Systems

GENERAL DESCRIPTION

The AD7774 is a complete analog I/O port comprising three DACs (two 8-bit and one 11-bit) with output amplifiers, four input channels, two track/hold amplifiers and an 8-bit ADC. It has versatile input and output signal-conditioning features which make it ideal for use in head-positioning servos in dedicated-only and combined dedicated/embedded disk systems and other closed-loop digital servo systems.

The part contains four input channels, grouped in pairs. V_{A1} and V_{A2} share a common track/hold amplifier, Track/Hold A, while V_{B1} and V_{B2} share Track/Hold B. Either single or double conversions can be performed. In single conversion mode, any one of the four input channels can be converted. In double conversion mode, either V_{A1} and V_{B1} or V_{A2} and V_{B2} are simultaneously held by Track/Hold A and Track/Hold B, and the held voltages are sequentially converted.

The center point of the transfer function (the bias voltage) can be set for all input and output channels. This makes the AD7774 especially useful in disk drives, where only a positive supply rail is available, as it allows the analog input and output voltages to be referred to a point other than analog ground. In addition, the input span (the swing around the bias voltage) can be set for the input channels. The output span for all three channels is set by the on-chip reference.



The AD7774 operates from +5 V and +12 V supplies. It is fabricated in Linear Compatible CMOS (LC²MOS), an advanced, mixed technology process that combines precision bipolar circuits with low power CMOS logic. The part is available in a 28-lead dual-in-line (DIP) package and in a 28-terminal plastic leaded chip carrier (PLCC) package.

PRODUCT HIGHLIGHTS

1. The AD7774 contains a four-channel, 3.6 µs ADC with input signal conditioning and three DACs with output amplifiers and output signal conditioning, on a single chip.
2. The midpoint of the ADC transfer function, the input voltage swing of the ADC and the midpoint output voltage of the DACs can be set by applying ground referenced control voltages.
3. The AD7774 interface timing is compatible with most modern microcontrollers and digital signal processors.

I_{DD}	33	mA max	DACs Loaded with Full Scale; All Analog Inputs = V_{BIAS}
I_{CC}	8	mA max	Logic Inputs = 0.8 V or 2.4 V

NOTES

[1]Temperature range: 0°C to +70°C.

[2]With V_{SWING} = 2.5 V and DB0–DB3 of the ADC Control Register = 0, 1 LSB = (2*V_{SWING})/256 = 19.5 mV.
With V_{SWING} = 2.5 V and DB0–DB3 of the ADC Control Register = 1, 1 LSB = (V_{SWING})/256 = 9.75 mV.

[3]See Terminology.

[4]The maximum V_{BIAS} voltage is limited by the requirement $V_{BIAS} + V_{SWING}$ (or $V_{SWING}/2$) ≤ V_{DD} − 2 V.

[5]The source impedance of the internally generated V_{SWING} is nominally 10 kΩ. If this internally generated V_{SWING} is required for use external to the AD7774, it is recommended that the V_{SWING} output is buffered.

[6]Sample tested at +25°C to ensure compliance.

Specifications subject to change without notice.

DAC SPECIFICATIONS

(V_{DD} = +10 V to +13.2 V; V_{CC} = +5 V ± 5%; AGND = DGND = 0 V; V_{BIAS} = +5 V; R_L = 10 kΩ, C_L = 100 pF to AGND.[1] All specifications T_{min} to T_{max} unless otherwise stated.)

NOTES

[1]The DACs will also operate to specification with a load of 5 kΩ and 100 pF to V_{BIAS}.

[2]Temperature range: 0°C to +70°C.

[3]1 LSB = $(2*V_{SWING})/2^N$, where N is the DAC resolution. 1 LSB = 2.44 mV for DAC A with V_{SWING} = 2.5 V; 1 LSB = 19.5 mV for DAC B, DAC C with V_{SWING} = 2.5 V.

[4]See Terminology.

[5]The maximum V_{BIAS} voltage is limited by the requirement $V_{BIAS} + V_{SWING} \leq V_{DD} - 2$ V.

[6]The source impedance of the internally generated V_{SWING} is nominally 10 kΩ. If this internally generated V_{SWING} is required for use external to the AD7774, it is recommended that the V_{SWING} output is buffered.

[7]DAC output span cannot be adjusted externally, i.e., adjusting V_{SWING} does not change the DAC output span.

[8]Sample tested at +25°C to ensure compliance.

Specifications subject to change without notice.

	150	ns max	Rising Edge of $\overline{WR}$ to Falling Edge of $\overline{BUSY}$; C_L = 100 pF
t_{15}	10	ns min	Address Valid to $\overline{CS}$ or $\overline{RD}$ Setup Time
t_{SAMP}	±50	ns max	ADC Channel to Channel Sampling Skew

NOTES
[1]Sample tested at +25°C to ensure compliance. All input signals are specified with tr = tf = 5 ns (10% to 90% of 5 V) and timed from a voltage level of 1.6 V.
[2]t_1 and t_2 are measured with the load circuit of Figure 1 and defined as the time required for an output to cross 0.8 V or 2,4 V.
[3]t_3 and t_4 are derived from the measured time taken by the data outputs to change 0.5 V when loaded with the circuit of Figure 1. The measured number is then extrapolated back to remove the effects of charging or discharging the 100 pF capacitor. This means that the times, t_3 and t_4, quoted in the timing characteristics are the true bus relinquish times of the part and as such are independent of external bus loading capacitance.

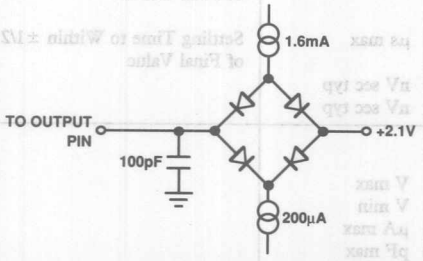

Figure 1. Load Circuits for Timing Measurements

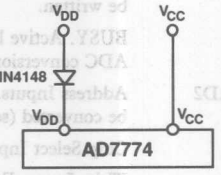
ORDERING GUIDE

Model	Temperature Range	Relative Accuracy	Package Option*
AD7774KN	0°C to +70°C	±1 LSB	N-28
AD7774KP	0°C to +70°C	±1 LSB	P-28A

*N = Plastic DIP Pacakge; P = Plastic Leaded Chip Carrier (PLCC) Package. For outline information see Package Information section.

ABSOLUTE MAXIMUM RATINGS*

T_A = +25°C unless otherwise noted



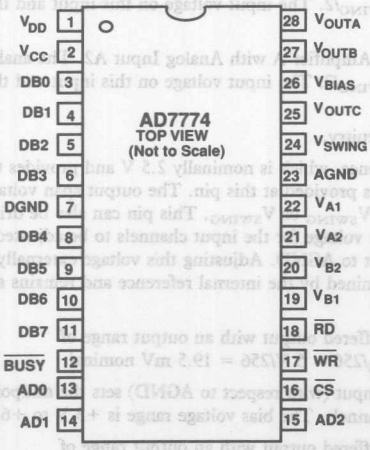
V_{DD} to AGND or DGND . . . . . −0.3 V, +15 V
V_{CC} to DGND . . . . . −0.3 V, V_{DD} + 0.3 V or +7 V (whichever is lower)
AGND to DGND . . . . . −0.3 V, V_{CC} + 0.3 V
$\overline{CS}$, $\overline{RD}$, $\overline{WR}$, AD0–AD2 to DGND . . . −0.3 V, V_{DD} + 0.3 V
DB0–DB7, $\overline{BUSY}$ to DGND . . . . . −0.3 V, V_{CC} + 0.3 V
Analog Input Voltage to AGND . . . . . −0.3 V, V_{DD} + 0.3 V
Analog Output Voltage to AGND . . . . −0.3 V, V_{DD} + 0.3 V
Operating Temperature Range
Commercial (K Version) . . . . . 0°C to +70°C
Power Dissipation (Any Package) to +75°C . . . . . 1000 mW
Derates above +75°C by . . . . . 6 mW/°C
Storage Temperature Range . . . . . −65°C to +150°C
Lead Temperature (Soldering, 10 secs) . . . . . +300°C

*Stresses above those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. This is a stress rating only and functional operation of the device at these or any other conditions above those listed in the operational sections of this specification is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability. Only one Absolute Maximum Rating may be applied at any one time.

Note:
During power supply sequencing some of the absolute maximum rating specifications may be violated. The following specifications are allowed during power-up (for 5 seconds) without causing permanent damage to the device:

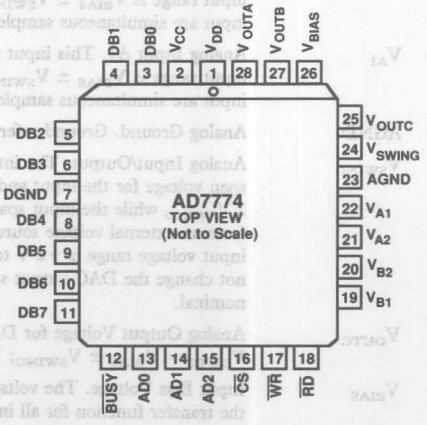
1) Digital Input Current, 100 mA.
2) V_{CC} to V_{DD} Current, 3A.

If the V_{CC} supply can provide more than 3A to V_{DD} during power supply sequencing or if V_{CC} can exceed V_{DD} by more than 0.3 V at any other time, the diode protection scheme shown below is recommended;



CAUTION

ESD (electrostatic discharge) sensitive device. The digital control inputs are diode protected; however, permanent damage may occur on unconnected devices subject to high energy electrostatic fields. Unused devices must be stored in conductive foam or shunts. The protective foam should be discharged to the destination socket before devices are inserted.



PIN CONFIGURATIONS

DIP

PLCC

8

Pin	Mnemonic	Description
1	V_{DD}	Analog Supply Voltage, +12 V nominal. This is used to power all analog circuitry on the part.
2	V_{CC}	Digital Supply Voltage, +5 V nominal. This is used to power all digital circuitry on the part.
3–6	DB0–DB3	Data Bit 0 to Data Bit 3 of the Input/Output Data Bus. This is a bidirectional data port from which ADC output data may be read and to which DAC input data and ADC Control Register data may be written.
7	DGND	Digital Ground. Ground reference for digital circuitry.
8–11	DB4–DB7	Data Bit 4 to Data Bit 7 of the Input/Output Data Bus. This is a bidirectional data port from which ADC output data may be read and to which DAC input data and ADC Control Register data may be written.
12	$\overline{BUSY}$	BUSY. Active low logic output indicating A/D converter status. The AD7774 is performing an ADC conversion if this output is low.
13–15	AD0–AD2	Address Inputs. These select the internal latches and registers and also the analog input channel to be converted (see TIMING AND CONTROL section).
16	$\overline{CS}$	Chip Select Input. The device is selected when this input is active.
17	$\overline{WR}$	Write Input. Edge-triggered logic input. It is used in conjunction with $\overline{CS}$ and AD0–AD2 to write data to the DAC registers and the ADC Control Register. Data is written to the registers on the rising edge of this $\overline{WR}$ input. The 11 bits of data for DAC A are written from the 8-bit data bus in two write operations. The rising edge of $\overline{WR}$ also starts conversion when AD0–AD2 are set to appropriate values (see ADC Control Register section).
18	$\overline{RD}$	Read Input. Active low logic input. It is used in conjunction with $\overline{CS}$ to enable the data outputs from the ADC latches.
19	V_{B1}	Analog Input B1. This input shares Track/Hold Amplifier B with Analog Input B2. The analog input range is $V_{BIAS} \pm V_{SWING}$ or $V_{BIAS} \pm V_{SWING}/2$. The input voltage on this input and the V_{A1} input are simultaneously sampled.
20	V_{B2}	Analog Input B2. This input shares Track/Hold Amplifier B with Analog Input B1. The analog input range is $V_{BIAS} \pm V_{SWING}$ or $V_{BIAS} \pm V_{SWING}/2$. The input voltage on this input and the V_{A2} input are simultaneously sampled.
21	V_{A2}	Analog Input A2. This input shares Track/Hold Amplifier A with Analog Input A1. The analog input range is $V_{BIAS} \pm V_{SWING}$ or $V_{BIAS} \pm V_{SWING}/2$. The input voltage on this input and the V_{B2} input are simultaneous sampled.
22	V_{A1}	Analog Input A1. This input shares Track/Hold Amplifier A with Analog Input A2. The analog input range is $V_{BIAS} \pm V_{SWING}$ or $V_{BIAS} \pm V_{SWING}/2$. The input voltage on this input and the V_{B1} input are simultaneous sampled.
23	AGND	Analog Ground. Ground reference for analog circuitry.
24	V_{SWING}	Analog Input/Output. The internal voltage reference, which is nominally 2.5 V and provides the span voltage for the input and output channels, is provided at this pin. The output span voltage is 2 V_{SWING} while the input span voltage can be 2 V_{SWING} or V_{SWING}. This pin can also be driven from an external voltage source to allow the span voltage for the input channels to be adjusted. The input voltage range is +2 V to +3 V with respect to AGND. Adjusting this voltage externally does not change the DAC output span which is determined by the internal reference and remains at 5 V nominal.
25	V_{OUTC}	Analog Output Voltage for DAC C. Eight-bit buffered output with an output range of $V_{OUTC} = V_{BIAS} \pm V_{SWING}$; 1 LSB = 2 $V_{SWING}/256$ = 5 V/256 = 19.5 mV nominal.
26	V_{BIAS}	Input Bias Voltage. The voltage applied to this input (with respect to AGND) sets the midpoint of the transfer function for all input and output channels. The bias voltage range is +3 V to +6.8 V.
27	V_{OUTB}	Analog Output Voltage for DAC B. Eight-bit buffered output with an output range of $V_{OUTB} = V_{BIAS} \pm V_{SWING}$; 1 LSB = 2 $V_{SWING}/256$ = 5 V/256 = 19.5 mV nominal.
28	V_{OUTA}	Analog Output Voltage for DAC A. Eleven-bit buffered output with an output range of $V_{OUTA} = V_{BIAS} \pm V_{SWING}$; 1 LSB = 2 $V_{SWING}/2048$ = 5 V/2048 = 2.44 mV nominal.

Relative Accuracy
For the AD7774 ADC, Relative Accuracy or endpoint nonlinearity is the maximum deviation, in LSBs, of the ADC's actual code transition points from a straight line drawn between the endpoints of the ADC transfer function.

For the DACs, Relative Accuracy or endpoint nonlinearity is a measure of the maximum deviation, in LSBs, from a straight line passing through the endpoints of the DAC transfer function.

Differential Nonlinearity
Differential Nonlinearity is the difference between the measured change and the ideal 1 LSB change between any two adjacent codes. A specified differential nonlinearity of ±1 LSB max ensures monotonicity (DAC) or no missed codes (ADC).

Bias Offset Error
For an ideal 8-bit ADC, the output code for an input voltage equal to V_{BIAS} should be 00 Hex. The ADC Bias Offset Error is the difference between the actual midpoint voltage for code 00 Hex and the input bias voltage, expressed in LSBs.

For an ideal DAC, the output voltage for code 000 Hex (DAC A) or code 00 Hex (DAC B, DAC C) should be equal to V_{BIAS}. The DAC Bias Offset Error is the difference between the actual output voltage and V_{BIAS}, expressed in LSBs.

Relative Offset Error
Relative Offset Error is the difference between the result of an internal bias conversion and the result of a conversion carried out with each of the analog inputs connected to V_{BIAS}.

Full-Scale Error (DAC)
The DACs in the AD7774 can be considered as having a bipolar (positive and negative) output range, but referred to the input bias voltage instead of AGND. Positive Full-Scale Error for the DACs is the difference, expressed in LSBs, between the actual output voltage for input code 3FF Hex (for DAC A) or 7F Hex (DAC B, DAC C) and the ideal voltage ($V_{BIAS} + V_{SWING} - 1$ LSB). Negative Full-Scale Error for the DAC is similarly specified for code 400 (DAC A) or code 80 (DAC B, DAC C), relative to the ideal output voltage ($V_{SWING} - V_{BIAS}$). Note that the full-scale errors for the DACs are measured after the bias offset errors have been adjusted out.

The input channels of the ADC can also be considered as having bipolar (positive and negative) input ranges, but referred to the input bias voltage instead of AGND. Positive Full-Scale Error for the ADC is the difference between the actual input voltage at the 7E to 7F code transition and the ideal input voltage ($V_{BIAS} + V_{SWING} - 1.5$ LSB), expressed in LSBs. Negative Full-Scale Error is similarly specified for the 81 to 80 code transition, relative to the ideal input voltage for this transition ($V_{BIAS} - V_{SWING} + 0.5$ LSB). Note that the full-scale errors for the ADC input channels are measured after their respective Bias Offset errors have been adjusted out.

Digital-to-Analog Glitch Impulse
Digital-to-Analog Glitch Impulse is the impulse injected into the analog output when the digital inputs change state with the DAC selected. It is normally specified as the area of the glitch in nV secs and is measured when the digital input code is changed from all 1s to all 0s.

Digital Feedthrough
Digital Feedthrough is also a measure of the impulse injected into the analog outputs from the digital inputs but is measured when the DAC is not selected. It is essentially feedthrough across the die and package. It is important in the AD7774 since it is a measure of the glitch impulse transferred to the analog output when data is read from the ADC latches. It is specified in nV secs and is measured with $\overline{WR}$ high and a digital code change from all 0s to all 1s.

TIMING AND CONTROL

The AD7774 contains two ADC data latches, an ADC control register and three DAC registers. Each of the ADC data latches contains a conversion result from the held voltage on its respective track/hold, i.e., ADC Latch A contains the result of a conversion performed on the held voltage on Track/Hold A, while ADC Latch B contains the results of a conversion done on the held voltage on Track/Hold B. The ADC control register determines whether a single or double conversion takes place and also determines the conversion sequence . In addition, it controls the analog input range for each channel.

Reading from the AD7774 accesses the contents of the ADC data latches. The $\overline{RD}$ input is a level-triggered input. Writing to the device either initiates conversion on the channel(s) determined by the ADC control register or loads data to the DAC registers. The $\overline{WR}$ input is an edge-triggered input. The following sections describe read, write and control register operations for the AD7774.

Read Operation

$\overline{CS}$	$\overline{RD}$	$\overline{WR}$	AD2	AD1	AD0	Function
1	X	X	X	X	X	No Read Operation.
X	1	X	X	X	X	No Read Operation.
0	0	X	X	X	0	The contents of ADC Latch A are output to the databus. This will contain the results of a conversion on either V_{A1} or V_{A2} (see ADC Control Register section).
0	0	X	X	X	1	The contents of ADC Latch B are output to the databus. This will contain the results of a conversion on either V_{B1} or V_{B2} (see ADC Control Register section).

Write Operation

$\overline{CS}$	$\overline{RD}$	$\overline{WR}$	AD2	AD1	AD0	Function
1	X	X	X	X	X	No Write Operation.
X	X	1	X	X	X	No Write Operation.
0	1	↓	0	0	0	DB0–DB7 are written to the upper 8 bits of the DAC A Register.
0	1	↓	0	0	1	DB5–DB7 are written to the lower 3 bits of the DAC A Register, and all 11 bits of the DAC A register are loaded to DAC A.
0	1	↓	0	1	0	DB0–DB7 are written into the DAC B Register and are loaded to DAC B.
0	1	↓	0	1	1	DB0–DB7 are written into the DAC C Register and are loaded to DAC C.
0	1	↓	1	0	0	Start conversion on either V_{A1} or V_{B1} or both (DB4 and DB5 of the ADC Control Register determine operation – see ADC Control Register section).
0	1	↓	1	0	1	Start conversion on either V_{A2} or V_{B2} or both (DB4 and DB5 of the ADC Control Register determine operation – see ADC Control Register section).
0	1	↓	1	1	0	Start conversion on either Track/Hold A bias voltage or Track/Hold B bias voltage or both (DB4 and DB5 of the ADC Control Register determine operation—see ADC Control Register section). See Bias Conversions section for explanation.
0	1	↓	1	1	1	DB0–DB5 is written to the ADC Control Register.

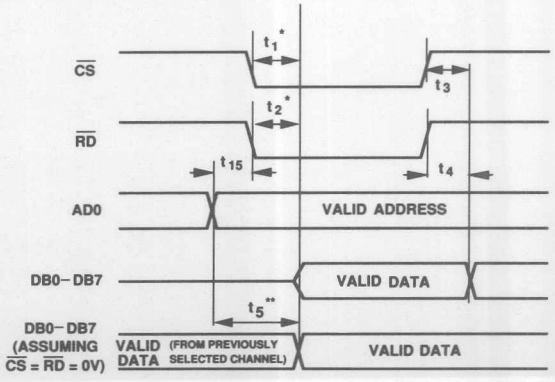
X = Don't Care.
A read during an ADC conversion may corrupt the data from the conversion in progress.

ADC Control Register

The ADC Control Register determines whether a single or double conversion takes place and also which track/hold output is converted when a write operation to start conversion takes place. The single/double conversion is determined by DB4 (see below). A double conversion means that both track/holds go into hold mode simultaneously, and the ADC converts both held voltages in sequence. The ADC status line, $\overline{BUSY}$, does not indicate that the conversion sequence has ended until both conversions are complete. In the single conversion mode, both track/holds again are simultaneously held but only one of these "held" voltages is converted—the other is ignored. The ADC status line, $\overline{BUSY}$, indicates that the conversion sequence has ended after one track/hold voltage has been converted. DB5 determines which track/hold voltage is converted in the single conversion mode. The ADC Control Register also determines the analog input voltage range for all four inputs (see DB0–DB3 below).

ADC Control Register Bit	Function
DB0	V_{A1} Input Voltage Range
0	Input Range is $V_{BIAS} \pm V_{SWING}$
1	Input Range is $V_{BIAS} \pm V_{SWING}/2$
DB1	V_{A2} Input Voltage Range
0	Input Range is $V_{BIAS} \pm V_{SWING}$
1	Input Range is $V_{BIAS} \pm V_{SWING}/2$
DB2	V_{B1} Input Voltage Range
0	Input Range is $V_{BIAS} \pm V_{SWING}$
1	Input Range is $V_{BIAS} \pm V_{SWING}/2$
DB3	V_{B2} Input Voltage Range
0	Input Range is $V_{BIAS} \pm V_{SWING}$
1	Input Range is $V_{BIAS} \pm V_{SWING}/2$
DB4	Single/Double Conversion
0	Double Conversion
1	Single Conversion
DB5	Conversion Sequence
0	First Conversion in the sequence is a V_A conversion[1, 2]
1	First Conversion in the sequence is a V_B conversion[1, 2]

NOTES



[1]A V_A conversion is a conversion on either V_{A1}, V_{A2}, or the bias voltage for Track/Hold A. Address inputs AD0, AD1 and AD2 determine which one of these signals is converted. A V_B conversion is a conversion on either V_{B1}, V_{B2}, or the bias voltage for Track/Hold B. Address inputs AD0, AD1 and AD2 determine which one of these signals is converted. (See previous page.)

[2]In the single conversion mode DB5 determines whether a V_A conversion or a V_B conversion takes place. In the double conversion mode, DB5 simply determines the order in which the two track/hold voltages are converted.

ADC Read Cycle

Figure 2 shows the timing diagram for a read operation for the AD7774. It consists of bringing both $\overline{CS}$ and $\overline{RD}$ low with data being accessed from one of the two on-chip ADC latches. Address line AD0 determines from which latch the data is accessed. With AD0 low, the contents of ADC Latch A are placed on the databus during a read operation; with AD0 high, a read operation will access the contents of ADC Latch B. ADC Latch A will contain the results of a conversion on either V_{A1} or V_{A2} or the results of a conversion on the bias voltage for Track/Hold A. ADC Latch B will contain the results of a conversion on V_{B1} or V_{B2} or the results of a conversion on the bias voltage for Track/Hold B.

Both the $\overline{CS}$ and $\overline{RD}$ inputs are level-triggered. If both are hardwired low, the data access time for a read cycle is determined from AD0.

* t_1 and t_2 are measured with t_{15} = 10ns

** t_5 is measured with $\overline{CS}$ = $\overline{RD}$ = 0V

Figure 2. AD7774 Read Cycle

8

A write operation to the AD7774 consists of writing data to the DAC registers or to the ADC Control Register. A write to the AD7774 can also initiate conversion on the ADC (see ADC Conversion Sequence section). The function of the write operation is determined by address bits AD0–AD2.

The $\overline{WR}$ input is an edge-triggered input, and data is only written to the on-chip registers on the rising edge of $\overline{WR}$. Data written to the DAC registers must be left justified to load correct data. For the 11-bit DAC A, this means that the upper 8 bits are loaded with the 11-bit MSB occupying the DB7 position on the databus. The lower three bits of the 11-bit word are loaded in a separate write cycle with DB0 of the 11-bit word occupying the DB5 position on the databus. Figure 3 shows the timing diagram for a write operation to the AD7774.

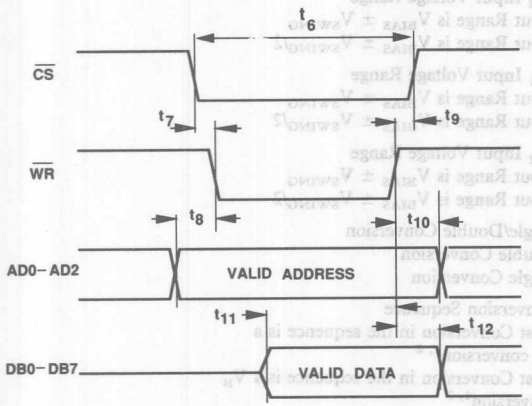


Figure 3. AD7774 Write Cycle

The AD7774 contains two track/hold amplifiers and one A/D converter. A conversion sequence can either consist of a single conversion or double conversion. In the double conversion mode, the track/holds go into hold mode simultaneously, and the held voltages are converted sequentially by the A/D converter. In the single conversion option, the track/holds again go into hold mode simultaneously, but only one voltage is converted—either the held voltage on Track/Hold A or Track/Hold B.

Figure 4 shows the timing diagram for the AD7774 conversion sequence. Conversion is initiated on the rising edge of $\overline{WR}$. Address lines AD0–AD2 determine which channel is to be converted. On the rising edge of $\overline{WR}$, the internal clock oscillator is activated, and the channel acquisition time begins. The $\overline{BUSY}$ output goes low to indicate that the conversion sequence has begun. The channel acquisition time takes approximately 1.5 μs, at which time the track/holds go into hold mode. The A/D converter then converts the held voltage on either Track/Hold A or Track/Hold B depending on the status of DB5 of the control register.

This first conversion takes a total of 3.6 μs maximum. In the single conversion mode, the conversion sequence is now complete, and the AD7774 indicates this by taking its $\overline{BUSY}$ status line high. In the double conversion mode, the conversion on the voltage held on the second track/hold starts at this time and runs for another 2.4 μs maximum. In this double conversion mode, the $\overline{BUSY}$ line does not return high until the second conversion is complete. At the end of conversion, either single or double, the internal clock oscillator is shut down.

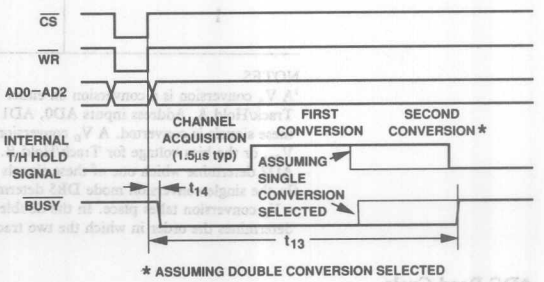

Figure 4. AD7774 Conversion Cycle

CIRCUIT DESCRIPTION

Analog Inputs and Outputs

The AD7774 provides the analog-to-digital and digital-to-analog conversion functions required between the microcontroller and the servo power amplifier in digital servo systems. It is intended primarily for closed-loop head positioning in dedicated-only and combined dedicated/embedded disk drives or other closed-loop digital servo applications. The ability to refer input and output signals to some voltage other than ground is of particular importance in disk drive applications. Typically, only +5 V digital and +12 V analog supply voltages are available, and the analog signals are often referred to a voltage around half the analog supply.

The AD7774 contains two track/hold amplifiers which feed a high speed, 8-bit, sampling ADC, each track/hold having two input channels. The part also contains three DACs with output amplifiers—one 11-bit DAC and two 8-bit DACs. A unique feature of the AD7774 is the input and output signal conditioning circuitry, which allows the analog input and output voltages to be referred to a point other than analog ground. The offset of the input channels and output channels is achieved by applying a ground-referenced, positive control voltage to the V_{BIAS} input of the AD7774. The voltage span of the input channels is set by applying a ground-referenced, positive control voltage to the V_{SWING} input of the part. The output voltage span from the DACs is set by the internal reference voltage.

Figure 5 shows the input voltage to output code relationship for the four input channels. The midpoint code of the input channels, 00 Hex (0000 0000 Binary), occurs at an input voltage equal to V_{BIAS}. Output coding from the ADC is 2s complement biased around this V_{BIAS} voltage.

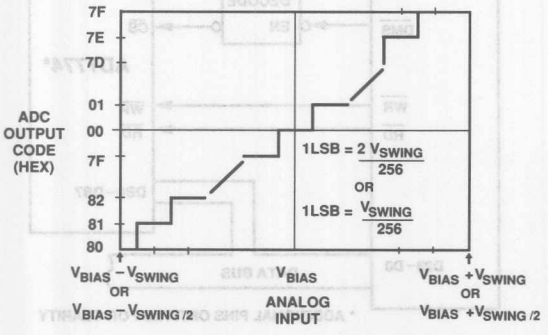

Figure 5. ADC Transfer Function

The input voltage range for the channels depends upon the status of bits DB0 to DB3 of the ADC control register. Each these bits controls the gain on one of the input channels (see ADC Control Register section). The input gain on each one of the input channels can either be a gain of 1 or a gain of 1/2. This results in an input voltage range which can be either $V_{BIAS} \pm V_{SWING}$ or $V_{BIAS} \pm V_{SWING}/2$.

For the first case, the full scale range (FSR) is 2 V_{SWING} and 1 LSB = 2 V_{SWING}/256. With the nominal V_{SWING} of +2.5 V, 1 LSB = 5 V/256 = 19.5 mV. The ideal first code transition (80 to 81 Hex) occurs at an analog input voltage equal to $V_{BIAS} - V_{SWING}$ + 0.5 LSB (negative full scale) and the ideal last code transition (7E to 7F Hex) occurs at an input voltage equal to $V_{BIAS} + V_{SWING}$ −1.5 LSBs (positive full scale).

For the second case, the full scale range (FSR) is V_{SWING} and 1 LSB = V_{SWING}/256. With the nominal V_{SWING} of +2.5 V, 1 LSB = 2.5 V/256 = 9.76 mV. The ideal first code transition (80 to 81 Hex) occurs at an analog input voltage equal to $V_{BIAS} - V_{SWING}/2$ + 0.5 LSB (negative full scale) and the ideal last code transition (7E to 7F Hex) occurs at an input voltage equal to $V_{BIAS} + V_{SWING}/2$ − 1.5 LSBs (positive full scale).

The input code to output voltage relationship for DAC A is shown in Figure 6. The DAC output voltage for an input code of 000 Hex is ideally equal to V_{BIAS}. Input coding to the DAC is 2s complement with the output voltage range biased around this V_{BIAS} voltage. The output voltage range is $V_{BIAS} \pm V_{SWING}$.

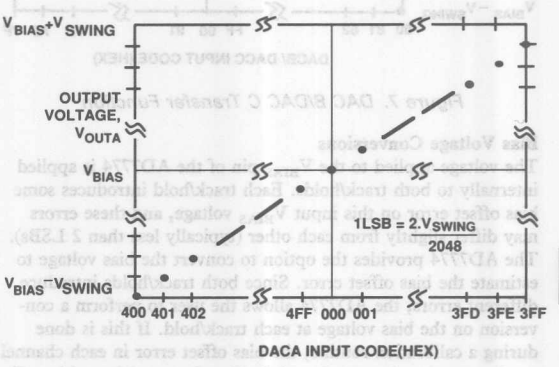

Figure 6. Transfer Function

The output range is 2 V_{SWING} where V_{SWING} is set by the internal reference voltage. The nominal DAC output swing is, therefore, 5 V and 1 LSB = 5 V/2048 = 2.44 mV. The bottom end of the transfer function occurs at an input code of 400 Hex and is ideally equal to $V_{BIAS} - V_{SWING}$. The top end of the transfer function occurs at an input code of 3FF Hex and is ideally equal to $V_{BIAS} + V_{SWING}$ −1 LSB.

The transfer function for both DAC B and DAC C is very similar to that outlined for DAC A. Once again, the output voltage range is $V_{BIAS} \pm V_{SWING}$. The V_{SWING} voltage is again set by the internal reference voltage. Therefore, the nominal output swing is 5 V and 1 LSB = 5 V/256 = 19.5 mV.

8

The DAC output voltage for an input code of 00 Hex is ideally equal to V_{BIAS}. Input coding to the DACs is 2s complement with the output voltage range biased around this V_{BIAS} voltage. The bottom end of the transfer function (negative full scale) occurs at an input code of 80 Hex and is ideally equal to $V_{BIAS} - V_{SWING}$. The top end of the transfer function (positive full scale) occurs at an input code of 7F Hex and is ideally equal to $V_{BIAS} + V_{SWING} - 1$ LSB. The input code to output voltage relationship for both DAC B and DAC C is shown in Figure 7.

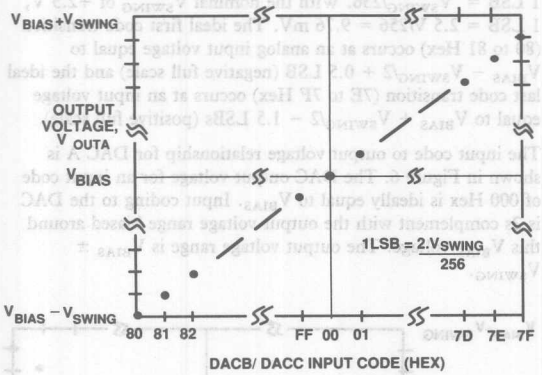

Figure 7. DAC B/DAC C Transfer Function

Bias Voltage Conversions

The voltage applied to the V_{BIAS} pin of the AD7774 is applied internally to both track/holds. Each track/hold introduces some bias offset error on this input V_{BIAS} voltage, and these errors may differ slightly from each other (typically less than 2 LSBs). The AD7774 provides the option to convert the bias voltage to estimate the bias offset error. Since both track/holds introduce different errors, the AD7774 allows the user to perform a conversion on the bias voltage at each track/hold. If this is done during a calibration routine, the bias offset error in each channel can be stored and compensated for in software. After a bias offset conversion for Track/Hold A, the results are stored in ADC Latch A and for a bias offset conversion for Track/Hold B, the results are stored in ADC Latch B.

Driving the Analog Inputs and Reference Inputs

The analog inputs, V_{A1}, V_{A2}, V_{B1} and V_{B2} require up to 1 mA of input current and as such must be driven from low output impedance sources. In addition, the V_{BIAS} and V_{SWING} inputs must also be driven from low impedance sources. The V_{SWING} pin provides the internally generated swing voltage, but this can be overdriven by an externally applied voltage. This externally applied voltage will generate the V_{SWING} voltage for the ADC but the V_{SWING} for the DACs is always generated from the internal swing voltage.

MICROPROCESSOR/MICROCOMPUTER INTERFACING

The AD7774 is designed for easy interfacing to microprocessors and microcomputers as a memory mapped peripheral or an I/O device. In addition, the AD7774 high speed bus timing allows direct interfacing to most microprocessors including the DSP processors.

AD7774–ADSP-2101/ADSP-2105 Interface

Figure 8 shows a typical interface to the DSP microcomputer, the ADSP-2101/ADSP-2105. The ADSP-2101/ADSP-2105 is optimized for high speed numeric processing tasks.

Because the instruction cycle of the ADSP-2101/ADSP-2105 is very fast, the $\overline{WR}$ and $\overline{RD}$ pulses must be stretched out to suit the AD7774. This is easily achieved as the ADSP-2101/ADSP-2105 memory interface supports slower memories and memory-mapped peripherals with a programmable wait state generation capability. A number of wait states, from 0 to 7, can be specified for each memory interface. One wait state is sufficient for the interface to the AD7774.

Conversion is initiated on the required ADC channel using a <DM(CST) = MR0> where CST is the relevant channel address. Writing data to the relevant AD7774 DAC or to the AD7774 ADC control register consists of a <DM(DAC) = MR0> instruction where DAC is the relevant DAC address or the address of the ADC control register. Two write operations are required to load the 11 bits of data to DAC A. A conversion result is read using the instruction <MR0 = DM(ADC)> where ADC is the address of the relevant ADC Latch.

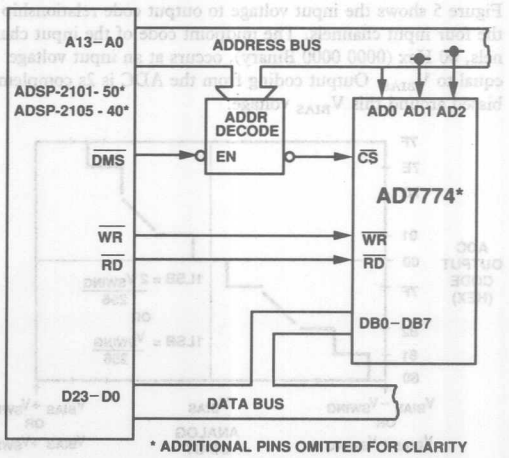

Figure 8. AD7774 to ADSP-2101/ADSP-2105 Interface

AD7774—TMS320C10/TMS320C14 Interface

A typical interface to the TMS320C10/TMS320C14 is shown in Figure 9. The AD7774 is mapped at a port address, and the interface is designed for the maximum TMS320C10 clock frequency of 20 MHz and the maximum clock frequency of 25 MHz for the TMS320C14.

Conversion is initiated on the selected AD7774 ADC channel using a single I/O instruction, <OUT CST,A> where CST is the relevant address for the selected channel. Writing data to the relevant AD7774 DAC or to the AD7774 ADC control register consists of an <OUT DAC,A> instruction where DAC is the relevant DAC address or the address of the ADC control regis-

ter. Two write operations are required to load the 11 bits of data to DAC A. A conversion result is read using the instruction <IN A,ADC> where ADC is the address of the relevant ADC Latch.

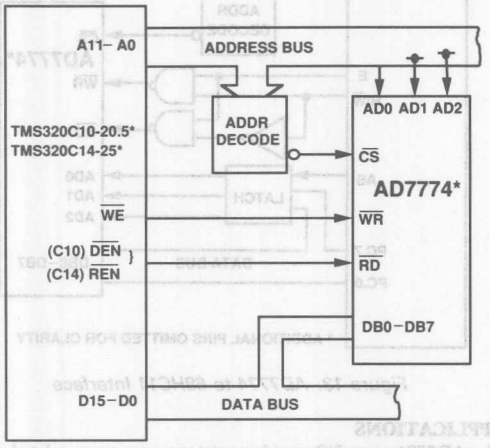

Figure 9. AD7774 to TMS320C10/TMS320C14 Interface

AD7774–TMS320C25 Interface

Figure 10 shows an interface between the TMS320C25 and the AD7774. The TMS320C25 does not have separate RD and WR signals to drive the AD7774 RD and WR inputs directly. These have to be generated from the processor STRB and R/W outputs with the addition of some logic gates.

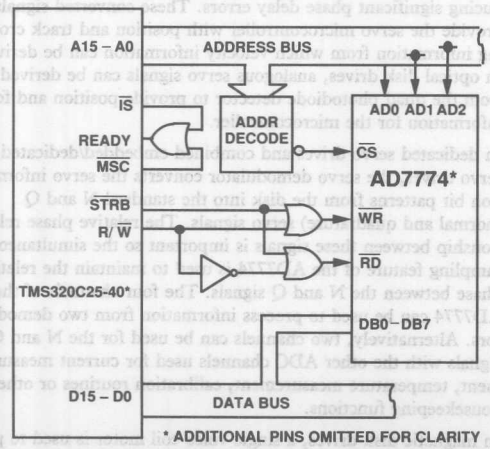

Figure 10. AD7774 to TMS320C25 Interface

Once again, because the processor cycle time is so fast a wait state has to be inserted during read and write cycles to the AD7774. This is achieved by OR-gating the IS signal with the MSC signal to drive the READY input and, thereby, generate one wait state during every read and write operation to the AD7774.

Conversion is initiated on the selected AD7774 ADC channel using a single I/O instruction, <OUT CST,A> where CST is the relevant address for the selected channel. Writing data to the relevant AD7774 DAC or to the AD7774 ADC control register consists of an <OUT DAC,A> instruction where DAC is the relevant DAC address or the address of the ADC control register. Two write operations are required to load the 11 bits of data to DAC A. A conversion result is read using the instruction < IN A,ADC > where ADC is the address of the relevant ADC Latch.

AD7774–80C196 Interface

Figure 11 shows a typical interface between the AD7774 and the 80C196 microcomputer. The microcomputer is configured in its 8-bit bus cycle mode and in the address valid strobe mode. In this mode, the high order 8 bits of the address bus appear on Port 4, while Port 3 contains the multiplexed data bus and lower order address bus.

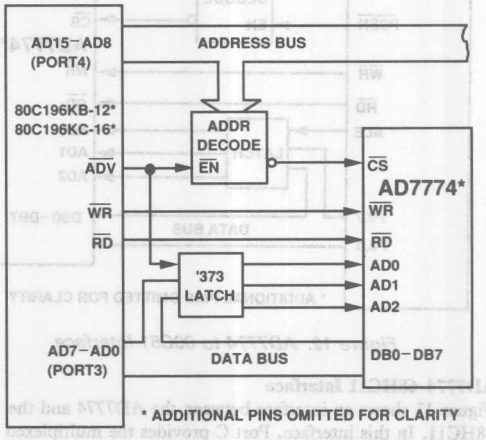

Figure 11. AD7774 to 80C196 Interface

Conversion is initiated on the selected AD7774 ADC channel using a single I/O instruction, <STB CST,D> where CST is the relevant address for the selected channel and D is a location in the 80C196 register file or is immediate data. Writing data to the relevant AD7774 DAC or to the AD7774 ADC control register consists of an <STB DAC,D> instruction where DAC is the relevant DAC address or the address of the ADC control register and D is a location in the 80C196 register file or is immediate data. Two write operations are required to load the 11 bits of data to DAC A. A conversion result is read using the instruction <LDB D,ADC> where ADC is the address of the relevant ADC latch and D is a location in the 80C196 register file.

8

AD7774–80C51 Interface

A typical interface between the AD7774 and the 80C51 is shown in Figure 12. In this interface, Port 0 provides the multiplexed low order address and data bus, and Port 2 provides the high order address bus. The ALE signal from the 80C51 is used to demultiplex the address/data bus.

Conversion is initiated on the selected AD7774 ADC channel using a single instruction, <MOV CST,A> where CST is the relevant address for the selected channel and A is the 80C51 accumulator. Writing data to the relevant AD7774 DAC or to the AD7774 ADC control register consists of an <MOV DAC,A> instruction where DAC is the relevant DAC address or the address of the ADC control register, and A is the 80C51 accumulator. Two write operations are required to load the 11 bits of data to DAC A. A conversion result is read using the instruction <MOV A,ADC> where ADC is the address of the relevant ADC Latch and A is the 80C51 accumulator.

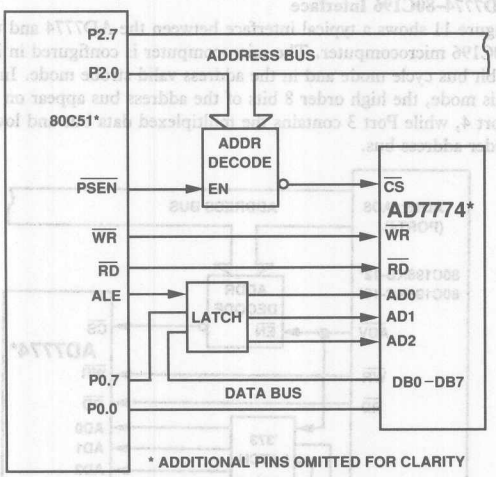

Figure 12. AD7774 to 80C51 Interface

AD7774–68HC11 Interface

Figure 13 shows an interface between the AD7774 and the 68HC11. In this interface, Port C provides the multiplexed low order address and data bus, and Port B provides the high order address bus. The AS signal from the 68HC11 is used to demultiplex the address/data bus. The 68HC11 does not have separate $\overline{RD}$ and $\overline{WR}$ signals to drive the AD7774 $\overline{RD}$ and $\overline{WR}$ inputs directly. These have to be generated from the processor E and R/$\overline{W}$ outputs with the addition of some logic gates.

Conversion is initiated on the selected AD7774 ADC channel using a single instruction, <STAA CST> where CST is the relevant address for the selected channel. Writing data to the relevant AD7774 DAC or to the AD7774 ADC control register consists of an <STAA DAC> instruction where DAC is the relevant DAC address or the address of the ADC control register, and the data is loaded to the relevant register from the 68HC11 accumulator. Two write operations are required to load the 11 bits of data to DAC A. A conversion result is read using the instruction <LDAA ADC> where ADC is the address of the relevant ADC latch, and the conversion result is loaded to the 68HC11 accumulator.

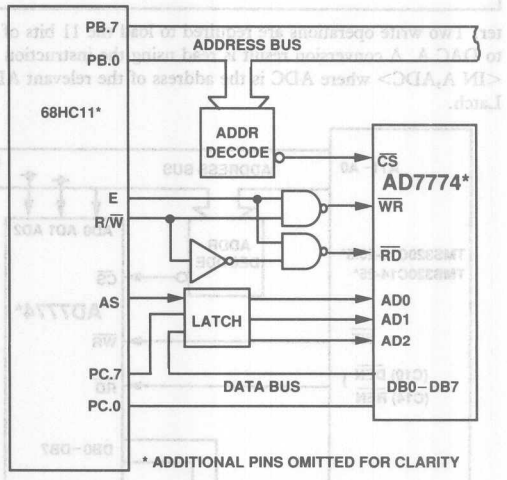

Figure 13. AD7774 to 68HC11 Interface

APPLICATIONS

The AD7774 servo I/O port is used to convert servo-related signals between the analog and digital domains. The input structure of the ADC makes it very easy to convert the typical output signals provided by a servo demodulator.

In a magnetic disk drive employing a dedicated servo surface or a combined embedded/dedicated servo surface, the servo demodulator produces two, positive-only, quadrature signals, generally sinusoidal or triangular, from the di-bit patterns read from the servo surface. The quadrature signals have the form of $V_{BIAS} \pm V_{SWING}$. The simultaneous sampling of the AD7774 input channels allows conversion of these quadrature signals without introducing significant phase delay errors. These converted signals provide the servo microcontroller with position and track crossing information from which velocity information can be derived. In optical disk drives, analogous servo signals can be derived from the quad photodiode detector to provide position and focus information for the microcontroller.

In dedicated servo drives and combined embedded/dedicated servo drives, the servo demodulator converts the servo information bit patterns from the disk into the standard N and Q (normal and quadrature) servo signals. The relative phase relationship between these signals is important so the simultaneous sampling feature of the AD7774 is used to maintain the relative phase between the N and Q signals. The four channels of the AD7774 can be used to process information from two demodulators. Alternatively, two channels can be used for the N and Q signals with the other ADC channels used for current measurement, temperature measurement, calibration routines or other housekeeping functions.

In magnetic disk drives, a single voice coil motor is used to position the head assembly and one DAC is usually sufficient to drive the motor in both the seek and track modes. In the seek mode the DAC can be used to generate directly the desired analog velocity trajectory which the head must travel in order to achieve minimum access times. Alternatively the DAC can generate a servo error value (computed by the microcontroller) between the actual head velocity and the desired head velocity. In

the track mode, the DAC can be used to provide a position error signal to keep the head over the track or to detect the head off-track, for such purposes as thermal compensation and soft-error retries. The DACs provide positive-only output signals of the form $V_{BIAS} \pm V_{SWING}$, which are ideal for driving voice coil motors. In general, up to 11 bits of resolution are required for a DAC to control the motor in both the seek and track modes. As a result, DAC A would generally be used to drive the voice coil motor. The other DAC channels can be used for programmable control of the loop filter or for AGC or programmable gain control.

A typical servo control loop using the AD7774 is shown in Figure 14. In this dedicated servo example, the servo demodulator outputs (the N and Q signals) are applied to the V_{A1} and V_{B1} inputs of the AD7774. The voice coil motor current, I_L, is bidirectional and is supplied by the power transconductance amplifier. One input to this amplifier is held at V_{BIAS} while the other input is driven from the DAC A output, V_{OUTA}. Typical input voltages for this power stage are shown in Figure 15. The transconductance, G_O, of the power stage is determined by external sense resistors.

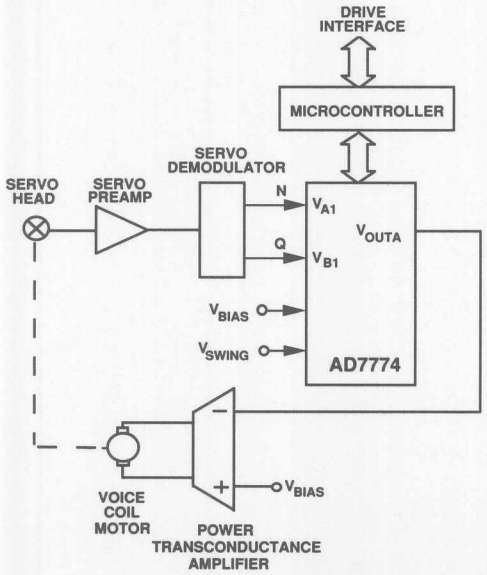

Figure 14. Typical Dedicated Servo Control Loop Using the AD7774

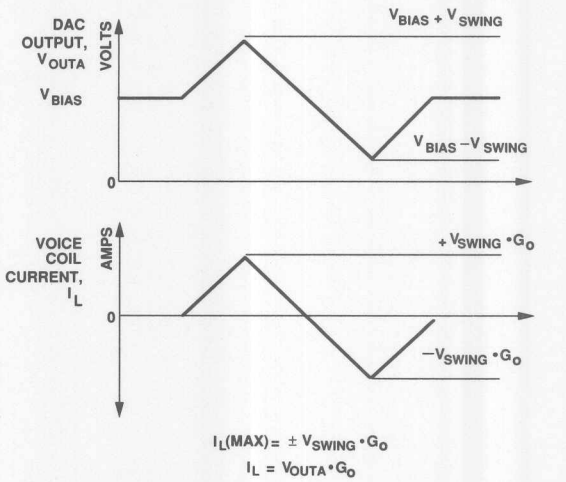

Figure 15. Typical Relationship Between Input Voltage and Output Current for Transconductance Amplifier

Multichannel Expansion

The AD7774 with its four input channels has the capability of monitoring the N and Q signals from two servo demodulators. With the addition of a multiplexer and a dual op amp, the system can be expanded so that the AD7774 handles the outputs from a number of servo demodulators. Using a differential multiplexer as shown in Figure 16, the N and Q signals for each servo demodulator can still be simultaneously sampled. The ADG527A multiplexer is ideally suited since it is specified for single supply operation (12 V ± 10%).

The $\overline{CS}$ and $\overline{WR}$ inputs to the AD7774 are gated to provide the $\overline{WR}$ input to the ADG527A. The multiplexer input is selected on the falling edge of $\overline{WR}$ while the signal is latched on the rising edge. The AD7774 starts conversion also on the rising edge of $\overline{WR}$. Therefore, the output signal of the multiplexer must have settled to within 8 bits over the duration of the $\overline{WR}$ pulse. The t_{ON} ($\overline{WR}$) and settling time of the ADG527A determine the width of the $\overline{WR}$ pulse.

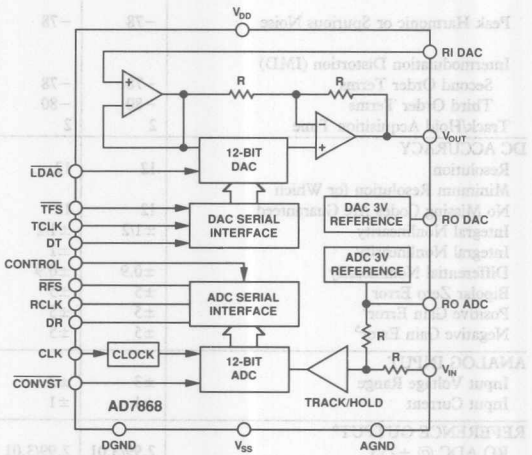
Complete, 12-Bit Analog I/O System

AD7868

FEATURES



Complete 12-Bit I/O System, Comprising:
- **12-Bit ADC with Track/Hold Amplifier**
  - **83 kHz Throughput Rate**
  - **72 dB SNR**
- **12-Bit DAC with Output Amplifier**
  - **3 μs Settling Time**
  - **72 dB SNR**
- **On-Chip Voltage Reference**

Operates from ±5 V Supplies
Low Power – 130 mW typ
Small 0.3″ Wide DIP

APPLICATIONS

Digital Signal Processing
Speech Recognition and Synthesis
Spectrum Analysis
High Speed Modems
DSP Servo Control

FUNCTIONAL BLOCK DIAGRAM

GENERAL DESCRIPTION

The AD7868 is a complete 12-bit I/O system containing a DAC and an ADC. The ADC is a successive approximation type with a track-and-hold amplifier having a combined throughput rate of 83 kHz. The DAC has an output buffer amplifier with a settling time of 3 μs to 12 bits. Temperature compensated 3 V buried Zener references provide precision references for the DAC and ADC.

Interfacing to both the DAC and ADC is serial, minimizing pin count and giving a small 24-pin package size. Standard control signals allow serial interfacing to most DSP machines. Asynchronous ADC conversion control and DAC updating is made possible with the $\overline{\text{CONVST}}$ and $\overline{\text{LDAC}}$ logic inputs.

The AD7868 operates from ±5 V power supplies, the analog input/output range of the ADC/DAC is ±3 V. The part is fully specified for dynamic parameters such as signal-to-noise ratio and harmonic distortion as well as traditional dc specifications.

The part is available in a 24-pin, 0.3″ wide, plastic or hermetic dual-in-line package (DIP) and in a 28-pin, plastic SOIC package.

PRODUCT HIGHLIGHTS

1. Complete 12-Bit I/O System.
   The AD7868 contains a 12-bit ADC with a track-and-hold amplifier and a 12-bit DAC with output amplifier. Also included are separate on-chip voltage references for the DAC and the ADC.
2. Dynamic Specifications for DSP Users.
   In addition to traditional dc specifications, the AD7868 is specified for ac parameters including signal-to-noise ratio and harmonic distortion. These parameters along with important timing parameters are tested on every device.
3. Small Package.
   The AD7868 is available in a 24-pin DIP and a 28-pin SOIC package.

t_{12}	40	40	ns min	$\overline{LDAC}$ Pulse Width

NOTES

[1]Timing specifications are sample tested at +25°C to ensure compliance. All input signals are specified with tr = tf = 5 ns (10% to 90% of 5 V) and timed from a voltage level of 1.6 V.

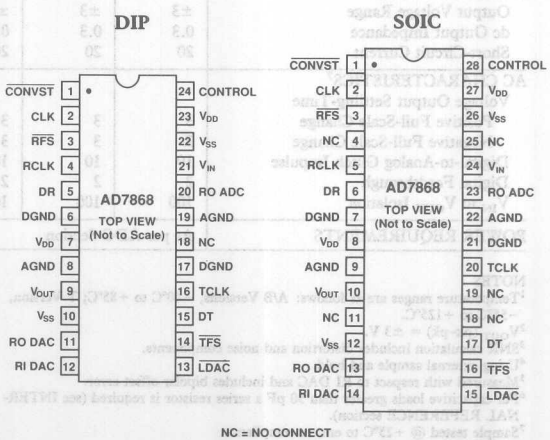
[2]Serial timing is measured with a 4.7 kΩ pull-up resistor on DR and $\overline{RFS}$ and a 2 kΩ pull-up resistor on RCLK. The capacitance on all three outputs is 35 pF.

[3]When using internal clock, RCLK mark/space ratio (measured form a voltage level of 1.6 V) range is 40/60 to 60/40. For external clock, RCLK mark/space ratio = external clock mark/space ratio.

[4]DR will drive higher capacitance loads but this will add to t_5 since it increases the external RC time constant (4.7 kΩ//C_L) and hence the time to reach 2.4 V.

[5]Time 2 RCLK to 3 RCLK depends on conversion start to ADC clock synchronization.

[6]TCLK mark/space ratio is 40/60 to 60/40.



ABSOLUTE MAXIMUM RATINGS*

*Stresses above those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. This is a stress rating only and functional operation of the device at these or any other conditions above those listed in the operational sections of this specification is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

PIN CONFIGURATIONS

CAUTION

ESD (electrostatic discharge) sensitive device. The digital control inputs are diode protected; however, permanent damage may occur on unconnected devices subject to high energy electrostatic fields. Unused devices must be stored in conductive foam or shunts. The protective foam should be discharged to the destination socket before devices are inserted.

PIN FUNCTION DESCRIPTION

DIP Pin Number	Mnemonic	Function
POWER SUPPLY		
7 & 23	V_{DD}	Positive Power Supply, 5 V ± 5%. Both V_{DD} pins must be tied together.
10 & 22	V_{SS}	Negative Power Supply, −5 V ± 5%. Both V_{SS} pins must be tied together.
8 & 19	AGND	Analog Ground. Both AGND pins must be tied together.
6 & 17	DGND	Digital Ground. Both DGND pins must be tied together.
ANALOG SIGNAL AND REFERENCE		
21	V_{IN}	ADC Analog Input. The ADC input range is ±3 V.
9	V_{OUT}	Analog Output Voltage from DAC. This output comes from a buffer amplifier. The range is bipolar, ±3 V with RI DAC = +3 V.
20	RO ADC	Voltage Reference Output. The internal ADC 3 V reference is provided at this pin. This output may be used as a reference for the DAC by connecting it to the RI DAC input. The external load capability of this reference is 500 μA.
11	RO DAC	DAC Voltage Reference Output. This is one of two internal voltage references. To operate the DAC with this internal reference, RO DAC should be connected to RI DAC. The external load capability of the reference is 500 μA.
12	RI DAC	DAC Voltage Reference Input. The voltage reference for the DAC must be applied to this pin. It is internally buffered before being applied to the DAC. The nominal reference voltage for correct operation of the AD7868 is 3 V.
ADC INTERFACE AND CONTROL		
2	CLK	Clock Input. An external TTL-compatible clock may be applied to this input. Alternatively, tying this pin to V_{SS} enables the internal laser-trimmed oscillator.
3	$\overline{RFS}$	Receive Frame Synchronization, Logic Output. This is an active low open-drain output which provides a framing pulse for serial data. An external 4.7 kΩ pull-up resistor is required on $\overline{RFS}$.
4	RCLK	Receive Clock, Logic Output. RCLK is the gated serial clock output which is derived from the internal or external ADC clock. If the CONTROL input is at V_{SS} the clock runs continuously. With the CONTROL input at DGND the RCLK output is gated off (three-state) after serial transmission is complete. RCLK is an open-drain output and requires an external 2 kΩ pull-up resistor.
5	DR	Receive Data, Logic Output. This is an open-drain data output used in conjunction with $\overline{RFS}$ and RCLK to transmit data from the ADC. Serial data is valid on the falling edge of RCLK when $\overline{RFS}$ is low. An external 4.7 kΩ resistor is required on the DR output.
1	$\overline{CONVST}$	Convert Start, Logic Input. A low to high transition on this input puts the track-and-hold amplifier into the hold mode and starts an ADC conversion. This input is asynchronous to the CLK input.
24	CONTROL	Control, Logic Input. With this pin at 0 V, the RCLK is noncontinuous. With this pin at −5 V, the RCLK is continuous. Note, tying this pin to V_{DD} places the part in a factory test mode where normal operation is not exhibited.
DAC INTERFACE AND CONTROL		
14	$\overline{TFS}$	Transmit Frame Synchronization, Logic Input. This is a frame or synchronization signal for the DAC with serial data expected after the falling edge of this signal.
15	DT	Transmit Data, Logic Input. This is the data input which is used in conjunction with $\overline{TFS}$ and TCLK to transfer serial data to the input latch.
16	TCLK	Transmit Clock, Logic Input. Serial data bits are latched on the falling edge of TCLK when $\overline{TFS}$ is low.
13	$\overline{LDAC}$	Load DAC, Logic Input. A new word is transferred into the DAC latch from the input latch on the falling edge of this signal.
18	NC	No Connect.

8

CONVERTER DETAILS

The AD7868 is a complete 12-bit I/O port, the only external components required for normal operation are pull-up resistors for the ADC data outputs and power supply decoupling capacitors. It is comprised of a 12-bit successive approximation ADC with a track/hold amplifier, a 12-bit DAC with a buffered output and two 3 V buried Zener references, a clock oscillator and control logic.

ADC CLOCK

The AD7868 has an internal clock oscillator which can be used for the ADC conversion procedure. The oscillator is enabled by tying the CLK input to V_{SS}. The oscillator is laser trimmed at the factory to give a conversion time of between 8.5 and 10 μs. The mark/space ratio can vary from 40/60 to 60/40. Alternatively, an external TTL compatible clock may be applied to this input. The allowable mark/space ratio of an external clock is 40/60 to 60/40. RCLK is a clock output, used for the serial interface. This output is derived directly from the ADC clock source and can be switched off at the end of conversion with the CONTROL input.

ADC CONVERSION TIMING

The conversion time for both external clock and continuous internal clock can vary from 19 to 20 rising clock edges depending on the conversion start to ADC clock synchronization. If a conversion is initiated within 30 ns prior to a rising edge of the ADC clock, the conversion time will consist of 20 rising clock edges, i.e., 9.5 μs conversion time. For noncontinuous internal clock, the conversion time is always 19 rising clock edges.

ADC TRACK-AND-HOLD AMPLIFIER

The track-and-hold amplifier on the analog input of the AD7868 allows the ADC to accurately convert an input sine wave of 6 V peak–peak amplitude to 12-bit accuracy. The input impedance is typically 9 kΩ, an equivalent circuit is shown in Figure 1. The input bandwidth of the track/hold amplifier is much greater than the Nyquist rate of the ADC, even when the ADC is operated at its maximum throughput rate. The 0.1 dB cut-off frequency occurs typically at 500 kHz. The track/hold amplifier acquires an input signal to 12-bit accuracy in less than 2 μs.

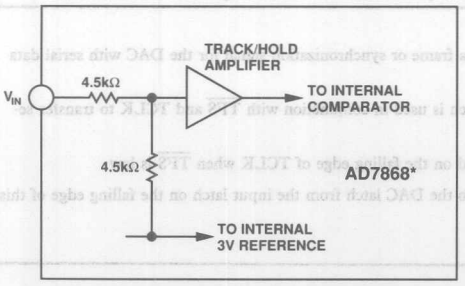

Figure 1. ADC Analog Input

The overall throughput rate is equal to the conversion time plus the track/hold amplifier acquisition time. For a 2.0 MHz input clock the throughput time is 12 μs max.

The operation of the track/hold amplifier is essentially transparent to the user. The track/hold amplifier goes from its track mode to its hold mode at the start of conversion on the rising edge of $\overline{CONVST}$.

INTERNAL REFERENCES

The AD7868 has two on-chip temperature compensated buried Zener references which are factory trimmed to 3 V ± 10 mV. One reference provides the appropriate biasing for the ADC, while the other is available as a reference for the DAC. Both reference outputs are available (labeled RO DAC and RO ADC) and are capable of providing up to 500 μA to an external load.

The DAC input reference (RI DAC) can be sourced externally or connected to any of the two on-chip references. Applications requiring good full-scale error matching between the DAC and the ADC should use the ADC reference as shown in Figure 4.

The maximum recommended capacitance on either of the reference output pins for normal operation is 50 pF. If either of the reference outputs is required to drive a capacitive load greater than 50 pF, then a 200 Ω resistor must be placed in series with the capacitive load. The addition of decoupling capacitors, 10 μF in parallel with 0.1 μF, as shown in Figure 2, improves noise performance. The improvement in noise performance can be seen from the graph in Figure 3. Note, this applies for the DAC output only; reference decoupling components do not affect ADC performance. So, a typical application will have just the DAC reference source decoupled with the other one open circuited.

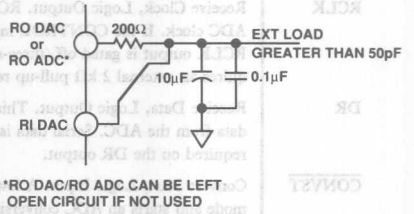

Figure 2. Reference Decoupling Circuitry

DAC OUTPUT AMPLIFIER

The output from the voltage-mode DAC is buffered by a noninverting amplifier. The buffer amplifier is capable of developing ±3 V across 2 kΩ and 100 pF load to ground and can produce 6 V peak-to-peak sine wave signals to a frequency of 20 kHz. The output is updated on the falling edge of the $\overline{LDAC}$ input. The output voltage settling time, to within 1/2 LSB of its final value, is typically less than 2 μs.

The small signal (200 mV p–p) bandwidth of the output buffer amplifier is typically 1 MHz. The output noise from the amplifier is low with a figure of 30 nV/$\sqrt{Hz}$ at a frequency of 1 kHz. The broadband noise from the amplifier exhibits a typical peak-to-peak figure of 150 μV for a 1 MHz output bandwidth. Figure 3 shows a typical plot of noise spectral density versus frequency for the output buffer amplifier and for either of the on-chip references.

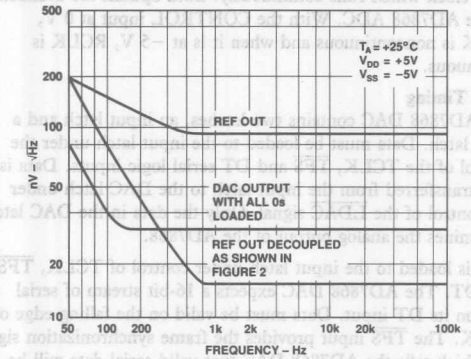

Figure 3. Noise Spectral Density vs. Frequency

INPUT/OUTPUT TRANSFER FUNCTIONS

A bipolar circuit for the AD7868 is shown in Figure 4. The analog input/output voltage range of the AD7868 is ±3 V. The designed code transitions for the ADC occur midway between successive integer LSB values (i.e., 1/2 LSB, 3/2 LSB, 5/2 LSB . . . FS – 3/2 LSBs). The input/output code is 2s complement binary with 1 LSB = FS/4096 = 1.46 mV. The ideal transfer function is shown in Figure 5.

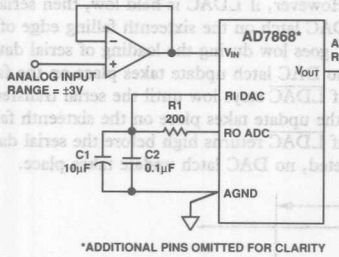

Figure 4. AD7868 Basic Bipolar Operation Using RO ADC as a Reference Input for the DAC

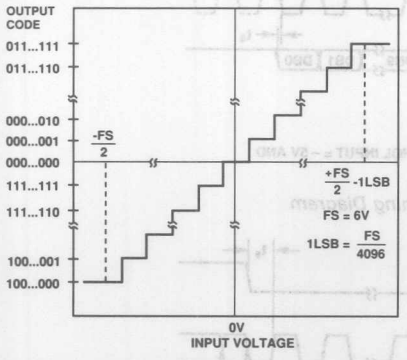

Figure 5. AD7868 Input/Output Transfer Function

OFFSET AND FULL-SCALE ADJUSTMENT

In most digital signal processing (DSP) applications, offset and full-scale errors have little or no effect on system performance. Offset error can always be eliminated in the analog domain by ac coupling. Full-scale errors do not cause problems as long as the input signal is within the full dynamic range of the ADC. For applications which require that the input signal range match the full analog input dynamic range of the ADC, offset and full-scale errors have to be adjusted to zero.

ADC ADJUSTMENT

Figure 6 has signal conditioning at the input and output of the AD7868 for trimming the end points of the transfer functions of both the ADC and the DAC. Offset error must be adjusted before full-scale error. For the ADC, this is achieved by trimming the offset of A1 while the input voltage, V1, is 1/2 LSB below ground. The trim procedure is as follows: apply a voltage of −0.73 mV (−1/2 LSB) at V1 in Figure 6 and adjust the offset voltage of A1 until the ADC output code flickers between 1111 1111 1111 (FFF HEX) and 0000 0000 0000 (000 HEX).

ADC gain error can be adjusted at either the first code transition (ADC negative full scale) or the last code transition (ADC positive full scale). The trim procedures for both cases are as follows (see Figure 6).

ADC Positive Full-Scale Adjustment

Apply a voltage of 2.9978 V (FS/2 − 3/2 LSBs) at V1. Adjust R2 until the ADC output code flickers between 0111 1111 1110 (7FE HEX) and 0111 1111 1111 (7FF HEX).

ADC Negative Full-Scale Adjustment

Apply a voltage of −2.9993 V (−FS/2 + 1/2 LSB) at V1 and adjust R2 until the ADC output code flickers between 1000 0000 0000 (800 HEX) and 1000 0000 0001 (801 HEX).

DAC ADJUSTMENT

Op amp A2 is included in Figure 6 for the DAC transfer function adjustment. Again offset must be adjusted before full scale. To adjust offset: load the DAC with 0000 0000 0000 (000 HEX) and trim the offset of A2 to 0 V. As with the ADC adjustment, gain error can be adjusted at either the first code transition (DAC negative full scale) or the last code transition (DAC positive full scale). The trim procedures for both cases are as follows:

DAC Positive Full-Scale Adjustment

Load the DAC with 0111 1111 1111 (7FF HEX) and adjust R7 until the op amp output voltage is equal to 2.9985 V, (FS/2 − 1 LSB).

DAC Negative Full-Scale Adjustment

Load the DAC with 1000 0000 0000 (800 HEX) and adjust R7 until the op amp output voltage is equal to 3.0 V (−FS/2).

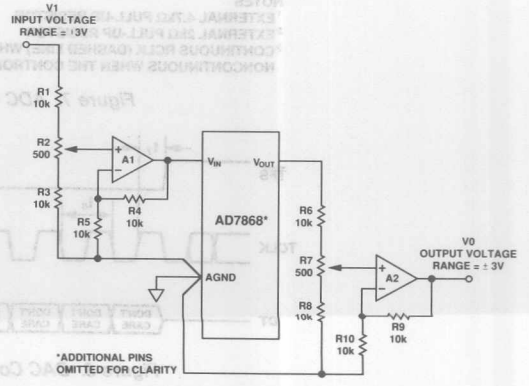

Figure 6. AD7868 with Input/Output Adjustment

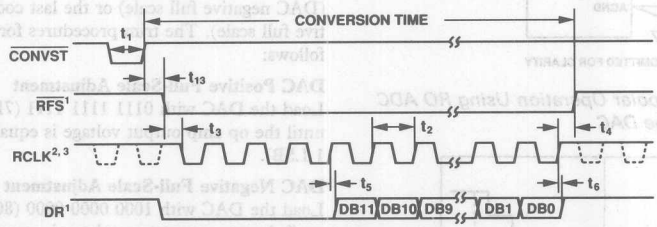
8

Communication with the AD7868 is managed by 6 dedicated pins. These consist of separate serial clocks, word framing or strobe pulses and data signals for both receiving and transmitting data. Conversion starts and DAC updating are controlled by two digital inputs; $\overline{\text{CONVST}}$ and $\overline{\text{LDAC}}$. These inputs can be asserted independently of the microprocessor by an external timer when precise sampling intervals are required. Alternatively, the $\overline{\text{LDAC}}$ and $\overline{\text{CONVST}}$ can be driven from a decoded address bus allowing the microprocessor control over conversion start and DAC updating as well as data communication to the AD7868.

ADC Timing

Conversion control is provided by the $\overline{\text{CONVST}}$ input. A low to high transition on $\overline{\text{CONVST}}$ input starts conversion and drives the track/hold amplifier into its hold mode. Serial data then becomes available while conversion is in progress. The corresponding timing diagram is shown in Figure 7. The word length is 16 bits; 4 leading zeros, followed by the 12-bit conversion result starting with the MSB. The data is synchronized to the serial clock output (RCLK) and is framed by the serial strobe ($\overline{\text{RFS}}$). Data is clocked out on a low to high transition of the serial clock and is valid on the falling edge of this clock while the $\overline{\text{RFS}}$ output is low. $\overline{\text{RFS}}$ goes low at the start of conversion and the first serial data bit (which is the first leading zero) is valid on the first falling edge of RCLK. All the ADC serial lines are open-drain outputs and require external pull-up resistors.

The serial clock out is derived from the ADC master clock source which may be internal or external. Normally, RCLK is required during the serial transmission only. In these cases it can be shut down (i.e., placed into high impedance) at the end of conversion to allow multiple ADCs to share a common serial bus. However, some serial systems (e.g., TMS32020) require a continuous serial clock. This can be achieved by using the CONTROL input on the AD7868 ADC. With the CONTROL input at 0 V, RCLK is noncontinuous and when it is at −5 V, RCLK is continuous.



DAC Timing

The AD7868 DAC contains two latches, an input latch and a DAC latch. Data must be loaded to the input latch under the control of the TCLK, $\overline{\text{TFS}}$ and DT serial logic inputs. Data is then transferred from the input latch to the DAC latch under the control of the $\overline{\text{LDAC}}$ signal. Only the data in the DAC latch determines the analog output of the AD7868.

Data is loaded to the input latch under control of TCLK, $\overline{\text{TFS}}$ and DT. The AD7868 DAC expects a 16-bit stream of serial data on its DT input. Data must be valid on the falling edge of TCLK. The $\overline{\text{TFS}}$ input provides the frame synchronization signal which tells the AD7868 DAC that valid serial data will be available for the next 16 falling edges of TCLK. Figure 8 shows the timing diagram for the serial data format.

Although 16 bits of data are clocked into the input latch, only 12 bits are transferred into the DAC latch. Therefore, 4 bits in the stream are don't cares since their value does not affect the DAC latch data. The bit positions are 4 don't cares followed by the 12-bit DAC data starting with the MSB.

The $\overline{\text{LDAC}}$ signal controls the transfer of data to the DAC latch. Normally, data is loaded to the DAC latch on the falling edge of $\overline{\text{LDAC}}$. However, if $\overline{\text{LDAC}}$ is held low, then serial data is loaded to the DAC latch on the sixteenth falling edge of TCLK. If $\overline{\text{LDAC}}$ goes low during the loading of serial data to the input latch, no DAC latch update takes place on the falling edge of $\overline{\text{LDAC}}$. If $\overline{\text{LDAC}}$ stays low until the serial transfer is completed, then the update takes place on the sixteenth falling edge of TCLK. If $\overline{\text{LDAC}}$ returns high before the serial data transfer is completed, no DAC latch update takes place.

NOTES
[1]EXTERNAL 4.7kΩ PULL-UP RESISTOR
[2]EXTERNAL 2kΩ PULL-UP RESISTOR

Figure 7. ADC Control Timing Diagram

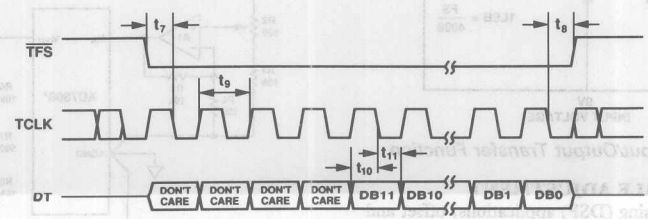

Figure 8. DAC Control Timing Diagram

The AD7868 is specified and 100% tested for dynamic performance specifications as well as traditional dc specifications such as integral and differential nonlinearity. These ac specifications are required for signal processing applications such as speech recognition, spectrum analysis, and high-speed modems. These applications require information on the converter's effect on the spectral content of the input signal. Hence, the parameters for which the AD7868 is specified include SNR, harmonic distortion and peak harmonics. These terms are discussed in more detail in the following sections.

Signal-to-Noise Ratio (SNR)

SNR is the measured signal-to-noise ratio at the output of the ADC or DAC. The signal is the rms magnitude of the fundamental. Noise is the rms sum of all the nonfundamental signals up to half the sampling frequency (fs/2) excluding dc. SNR is dependent upon the number of levels used in the quantization process; the more levels, the smaller the quantization noise. The theoretical signal-to-noise ratio for a sine wave input is given by

$$SNR = (6.02N + 1.76)\ dB \quad \ldots\ldots\ldots\ldots\ldots\ldots (1)$$

where N is the number of bits. Thus for an ideal 12-bit converter, SNR = 74 dB.

Effective Number of Bits

The formula given in Equation 1 relates the SNR to the number of bits. Rewriting the formula, as in Equation 2, it is possible to get a measure of performance expressed in effective number of bits (N).

$$N = \frac{SNR - 1.76}{6.02} \quad \ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots (2)$$

The effective number of bits for a device can be calculated directly from its measured SNR.

Harmonic Distortion

Harmonic distortion is the ratio of the rms sum of harmonics to the fundamental. For the AD7868, total harmonic distortion (THD) is defined as:

$$THD = 20\ log \frac{\sqrt{V_2^2 + V_3^2 + V_4^2 + V_5^2 + V_6^2}}{V_1}$$

where V_1 is the rms amplitude of the fundamental and V_2, V_3, V_4, V_5 and V_6 are the rms amplitudes of the second through to the sixth harmonic. The THD is also derived from the FFT plot of the ADC or DAC output spectrum.

ADC Testing

The output spectrum from the ADC is evaluated by applying a sinewave signal of very low distortion to the V_{IN} input which is sampled at an 83 kHz sampling rate. A Fast Fourier Transform (FFT) plot is generated from which the SNR data can be obtained. Figure 9 shows a typical 2048 point FFT plot of the AD7868BQ ADC with an input signal of 10 kHz and a sampling frequency of 83 kHz. The SNR obtained from this graph is 73 dB. It should be noted that the harmonics are taken into account when calculating the SNR.

frequency for an AD7868BQ with a sampling frequency of 83 kHz. The effective number of bits typically falls between 11.7 and 11.85 corresponding to SNR figures of 72.2 and 73.1 dB.

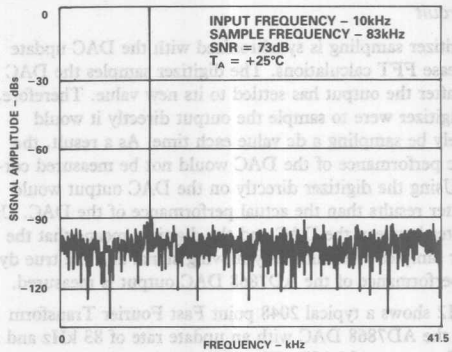

Figure 9. AD7868, ADC FFT Plot

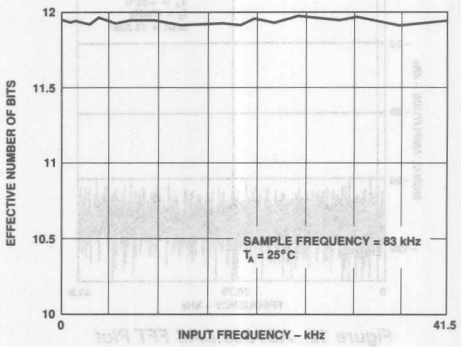

Figure 10. Effective Number of Bits vs. Frequency for the ADC

DAC Testing

A simplified diagram of the method used to test the dynamic performance specifications of the DAC is outlined in Figure 11. Data is loaded to the DAC under control of the microcontroller and associated logic. The output of the DAC is applied to a 9th order low-pass filter whose cut-off frequency corresponds to the Nyquist limit. The output of the filter is in turn applied to a 16-bit accurate digitizer. This digitizes the signal and the microcontroller generates an FFT plot from which the dynamic performance of the DAC can be evaluated.

8

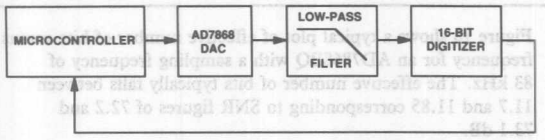

Figure 11. AD7868 DAC Dynamic Performance Test Circuit

The digitizer sampling is synchronized with the DAC update rate to ease FFT calculations. The digitizer samples the DAC output after the output has settled to its new value. Therefore, if the digitizer were to sample the output directly it would effectively be sampling a dc value each time. As a result, the dynamic performance of the DAC would not be measured correctly. Using the digitizer directly on the DAC output would give better results than the actual performance of the DAC. Using a filter between the DAC and the digitizer means that the digitizer samples a continuously moving signal and the true dynamic performance of the AD7868 DAC output is measured.

Figure 12 shows a typical 2048 point Fast Fourier Transform plot for the AD7868 DAC with an update rate of 83 kHz and an output frequency of 1 kHz. The SNR obtained from the graph is 73 dBs.

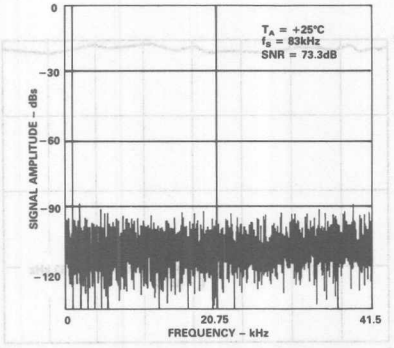

Figure 12. AD7868 DAC FFT Plot

Some applications will require improved performance versus frequency from the AD7868 DAC. In these applications, a simple sample-and-hold circuit such as that outlined in Figure 13 will extend the very good performance of the DAC to 20 kHz. Other applications will already have an inherent sample-and-hold function following the AD7868 DAC output. An example of this type of application is driving a switched-capacitor filter where the updating of the DAC is synchronized with the switched-capacitor filter. This inherent sample-and-hold function also extends the frequency range performance.

Performance versus Frequency

The typical performance plots of Figures 14 and 15 show the AD7868's DAC performance over a wide range of input frequencies at an update rate of 83 kHz. The plot of Figure 14 is without a sample-and-hold on the DAC output while the plot of Figure 15 is generated with a sample-and-hold on the output.

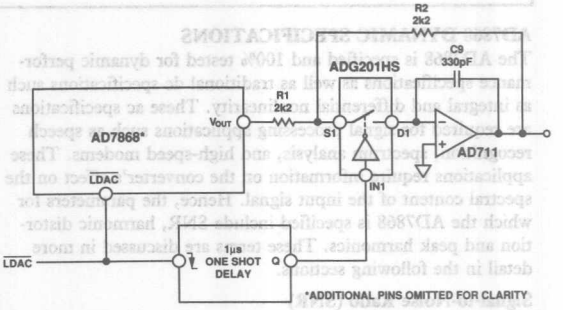

Figure 13. DAC Sample-and-Hold Circuit

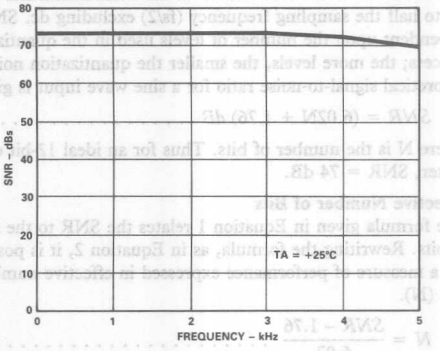

Figure 14. DAC Performance vs. Frequency (No Sample-and-Hold)

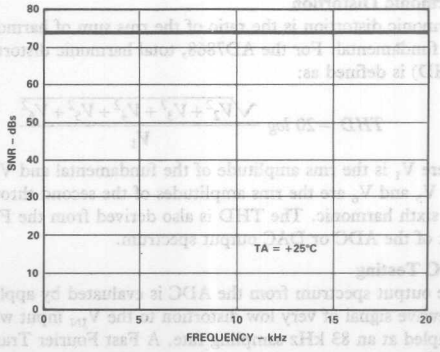

Figure 15. DAC Performance vs. Frequency (Sample-and-Hold)

MICROPROCESSOR INTERFACING

Microprocessor interfacing to the AD7868 is via a serial bus that uses standard protocol compatible with DSP machines. The communication interface consists of separate transmit (DAC) and receive (ADC) sections whose operations can be either synchronous or asynchronous with respect to each other. Each section has a clock signal, a data signal and a frame or strobe pulse. Synchronous operation means that data is transmitted from the ADC and to the DAC at the same time. In this mode only one interface clock is needed and this has to be the ADC clock out, so RCLK must be connected to TCLK. For asynchronous operation, DAC and ADC data transfers are independent of each other, the ADC provides the receive clock (RCLK) while the transmit clock (TCLK) may be provided by the processor or the ADC or some other external clock source.

Another option to be considered with serial interfacing is the use of a gated clock. A gated clock means that the device that is sending the data switches on the clock when data is ready to be transmitted and three states the clock output when transmission is complete. Only 16 clock pulses are transmitted with the first data bit getting latched into the receiving device on the first falling clock edge. Ideally, there is no need for frame pulses, however, the AD7868 DAC frame input ($\overline{TFS}$) has to be driven high between data transmissions. The easiest method is to use $\overline{RFS}$ to drive $\overline{TFS}$ and use only synchronous interfacing. This avoids the use of interconnects between the processor and AD7868 frame signals. Not all processors have a gated clock facility, Figure 16 shows an example with the DSP56000.

Table I below shows the number of interconnect lines between the processor and the AD7868 for the different interfacing options. The AD7868 has the facility to use different clocks for transmitting and receiving data. This option, however, only exists on some processors and normally just one clock (ADC clock) is used for all communication with the AD7868. For simplicity, all the interface examples in this data sheet use synchronous interfacing and use the ADC clock (RCLK) as an input for the DAC clock (TCLK). For a better understanding of each of these interfaces, consult the relevant processor data sheet.

Configuration	No. of Interconnects	Signals
Synchronous	4	RCLK, DR, DT and $\overline{RFS}$ ($TCLK = RCLK$, $\overline{TFS} = \overline{RFS}$)
Asynchronous*	5 or 6	RCLK, DR, $\overline{RFS}$, DT, $\overline{TFS}$ (TCLK = RCLK or µP serial CLK)
Synchronous Gated Clock	3	RCLK, DR and DT ($TCLK = RCLK$, $\overline{TFS} = \overline{RFS}$)

*5 LINES OF INTERCONNECT WHEN TCLK = RCLK
6 LINES OF INTERCONNECT WHEN TCLK = µP SERIAL CLK

Table I. Interconnect Lines for Different Interfacing Options

AD7868 – DSP56000 Interface

Figure 16 shows a typical interface between the AD7868 and DSP56000. The interface arrangement is synchronous with a gated clock requiring only three lines of interconnect. The DSP56000 internal serial control registers have to be configured for a 16-bit data word with valid data on the first falling clock edge. Conversion starts and DAC updating are controlled by an external timer. Data transfers, which occur during ADC conversions, are between the processor receive and transmit shift registers and the AD7868's ADC and DAC. At the end of each 16-bit transfer the DSP56000 receives an internal interrupt indicating the transmit register is empty and the receive register is full.

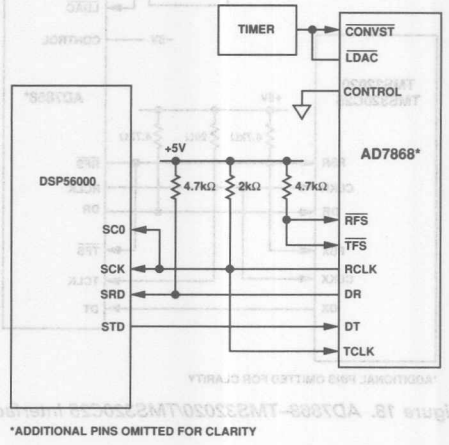

Figure 16. AD7868–DSP56000 Interface

AD7868 – ADSP-2101/ADSP-2102 Interface

An interface which is suitable for the ADSP-2101 or the ADSP-2102 is shown in Figure 17. The interface is configured for synchronous, continuous clock operation. The $\overline{LDAC}$ is tied low so the DAC gets updated on the sixteenth falling clock after $\overline{TFS}$ goes low. Alternatively $\overline{LDAC}$ may be driven from a timer as shown in Figure 16. As with the previous interface the processor receives an interrupt after reading or writing to the AD7868 and updates its own internal registers in preparation for the next data transfer.

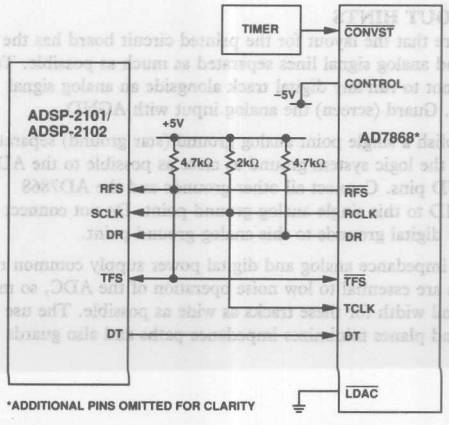

Figure 17. AD7868–ADSP-2101/ADSP-2102 Interface

AD7868 – TMS32020/TMS320C25 Interface

Figure 18 shows an interface which is suitable for the TMS32020/TMS320C25 processors. This interface is configured for synchronous, continuous clock operation. Note, the AD7868 will not interface correctly to these processors if the AD7868 is configured for a noncontinuous clock. Conversion starts and DAC updating are controlled by an external timer.

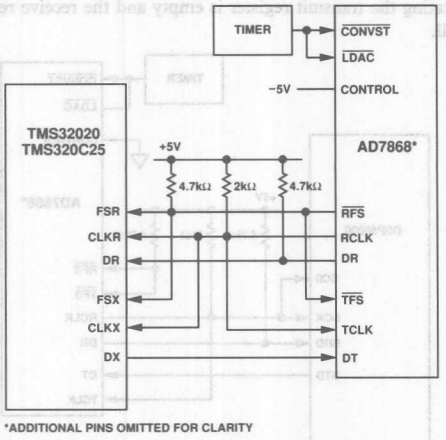

Figure 18. AD7868–TMS32020/TMS320C25 Interface

APPLICATION HINTS

Good printed circuit board (PCB) layout is as important as the circuit design itself in achieving high speed A/D performance. The AD7868's comparator is required to make bit decisions on an LSB size of 1.465 mV. To achieve this, the designer has to be conscious of noise both in the ADC itself and in the preceding analog circuitry. Switching mode power supplies are not recommended as the switching spikes will feed through to the comparator causing noisy code transitions. Other causes of concern are ground loops and digital feedthrough from microprocessors. These are factors which influence any ADC, and a proper PCB layout which minimizes these effects is essential for best performance.

LAYOUT HINTS

Ensure that the layout for the printed circuit board has the digital and analog signal lines separated as much as possible. Take care not to run any digital track alongside an analog signal track. Guard (screen) the analog input with AGND.

Establish a single point analog ground (star ground) separate from the logic system ground as close as possible to the AD7868 AGND pins. Connect all other grounds and the AD7868 DGND to this single analog ground point. Do not connect any other digital grounds to this analog ground point.

Low impedance analog and digital power supply common returns are essential to low noise operation of the ADC, so make the foil width for these tracks as wide as possible. The use of ground planes minimizes impedance paths and also guards the analog circuitry from digital noise. The circuit layout of Figures 22 and 23 have both analog and digital ground planes which are kept separated and only joined together at the AD7868 AGND pins.

NOISE

Keep the input signal leads to V_{IN} and signal return leads from AGND as short as possible to minimize input noise coupling. In applications where this is not possible, use a shielded cable between the source and the ADC. Reduce the ground circuit impedance as much as possible since any potential difference in grounds between the signal source and the ADC appears as an error voltage in series with the input signal.

INPUT/OUTPUT BOARD

Figure 19 shows an analog I/O board based on the AD7868. The corresponding printed circuit board (PCB) layout and silkscreen are shown in Figures 21 to 23.

The analog input to the AD7868 is buffered with an AD711 op amp. There is a component grid provided near the analog input on the PCB which may be used for an antialiasing filter for the ADC or a reconstruction filter for the DAC or any other conditioning circuitry. To facilitate this option, there are two wire links (labeled LK1 and LK2) required on the analog input and output tracks.

The board contains a SHA circuit which can be used on the output of the AD7868 DAC to extend the very good performance of the part over a wider frequency range. The increased performance from the SHA can be seen in Figures 14 and 15 of this data sheet. A wire link (labeled LK3) connects the board output to either the SHA output or directly to the AD7868 DAC output.

There are three $\overline{\text{LDAC}}$ link options on the board; $\overline{\text{LDAC}}$ can be driven from an external source independent of $\overline{\text{CONVST}}$, $\overline{\text{LDAC}}$ can be tied to $\overline{\text{CONVST}}$ or $\overline{\text{LDAC}}$ can be tied to GND. Choosing the latter option of tying $\overline{\text{LDAC}}$ to GND disables the SHA operation, and places the SHA permanently in the track mode.

Microprocessor connections to the board are made by a 9-way D-type connector. The pinout is shown in Figure 20. The ADC's digital outputs are buffered with 74HC4050s. These buffers provide a higher current output capability for high capacitance loads or cables. Normally, these buffers are not required as the AD7868 will be sitting on the same board as the processor.

POWER SUPPLY CONNECTIONS

The PCB requires two analog power supplies and one 5 V digital supply. Connections to the analog supply are made directly to the PCB as shown on the silkscreen in Figure 21. The connections are labeled V+ and V− and the range for both of these supplies is 12 V to 15 V. Connections to the 5 V digital supply are made through the D-type connector SKT6. The ±5 V analog supply required by the AD7868 are generated from two voltage regulators on the V+ and V− supplies.

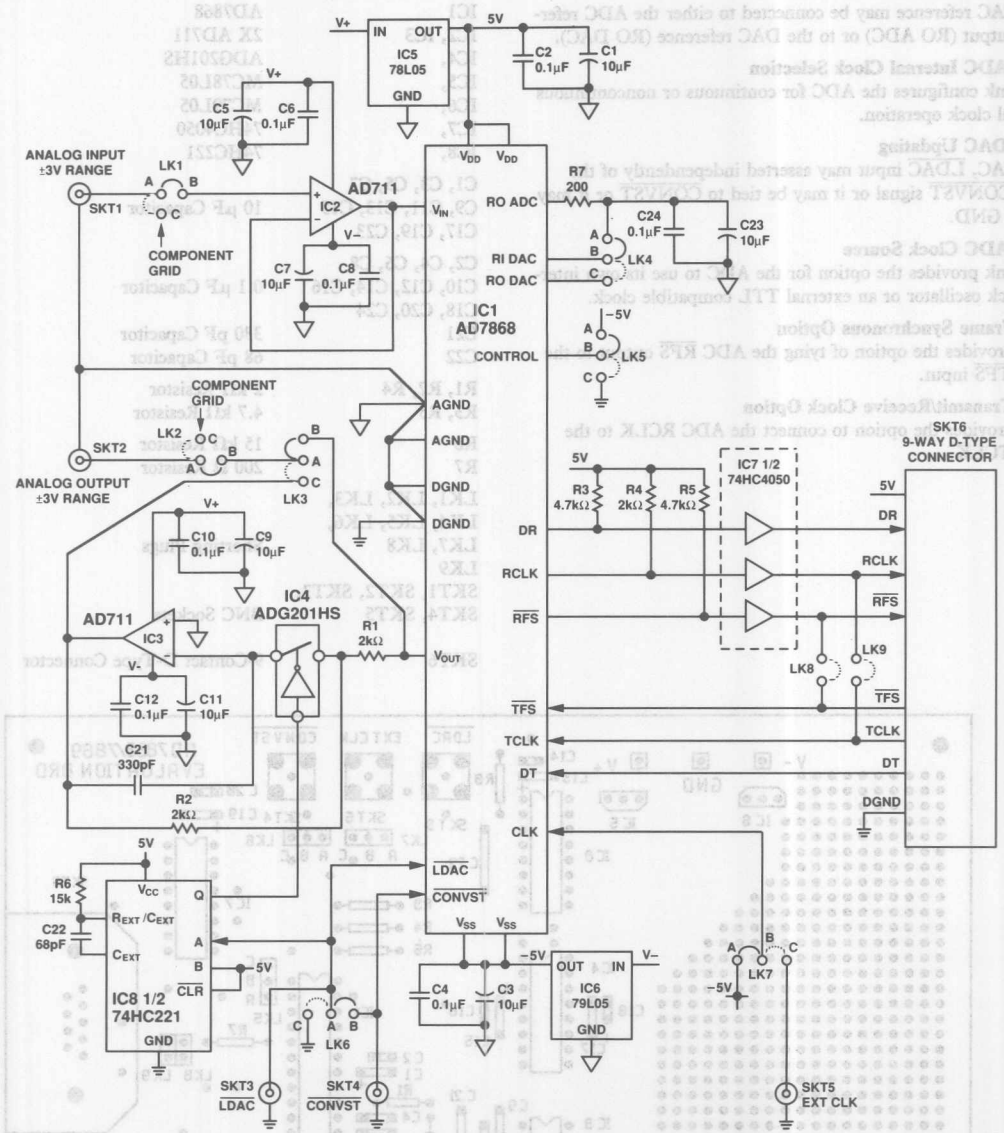

Figure 19. Input/Output Circuit Based on the AD7868

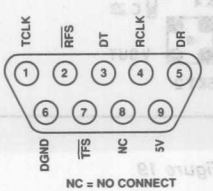

Figure 20. SKT6, D-Type Connector Pinout

WIRE LINK OPTIONS

LK1, Analog Input Link

LK1 connects the analog input to a component grid or to a buffer amplifier which drives the ADC input.

LK2, Analog Output Link

LK2 connects the analog output to the component grid or to either the SHA or DAC output (see LK3).

LK3, SHA or DAC Select

The analog output may be taken directly from the DAC or from a SHA at the output of the DAC.

LK4, DAC Reference Selection
The DAC reference may be connected to either the ADC reference output (RO ADC) or to the DAC reference (RO DAC).

LK5, ADC Internal Clock Selection
This link configures the ADC for continuous or noncontinuous internal clock operation.

LK6, DAC Updating
The DAC, $\overline{\text{LDAC}}$ input may asserted independently of the ADC $\overline{\text{CONVST}}$ signal or it may be tied to $\overline{\text{CONVST}}$ or it may tied to GND.

LK7, ADC Clock Source
This link provides the option for the ADC to use its own internal clock oscillator or an external TTL compatible clock.

LK8 Frame Synchronous Option
LK8 provides the option of tying the ADC $\overline{\text{RFS}}$ output to the DAC $\overline{\text{TFS}}$ input.

LK9 Transmit/Receive Clock Option
LK9 provides the option to connect the ADC RCLK to the DAC TCLK.

ANALOG DEVICES

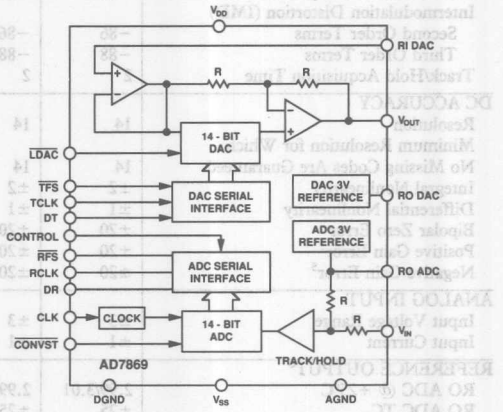
LC²MOS
Complete, 14-Bit Analog I/O System
AD7869

FEATURES
Complete 14-Bit I/O System, Comprising
14-Bit ADC with Track/Hold Amplifier
83 kHz Throughput Rate
14-Bit DAC with Output Amplifier
3.5 μs Settling Time
On-Chip Voltage Reference
Operates from ±5 V Supplies
Low Power – 130 mW typ
Small 0.3" Wide DIP

APPLICATIONS
Digital Signal Processing
Speech Recognition and Synthesis
Spectrum Analysis
High Speed Modems
DSP Servo Control

GENERAL DESCRIPTION

The AD7869 is a complete 14-bit I/O system containing a DAC and an ADC. The ADC is a successive approximation type with a track-and-hold amplifier having a combined throughput rate of 83 kHz. The DAC has an output buffer amplifier with a settling time of 4 μs to 14 bits. Temperature compensated 3 V buried Zener references provide precision references for the DAC and ADC.



Interfacing to both the DAC and ADC is serial, minimizing pin count and giving a small 24-pin package size. Standard control signals allow serial interfacing to most DSP machines.

Asynchronous ADC conversion control and DAC updating is made possible with the $\overline{\text{CONVST}}$ and $\overline{\text{LDAC}}$ logic inputs.

The AD7869 operates form ±5 V power supplies, the analog input/output range of the ADC/DAC is ±3 V. The part is fully specified for dynamic parameters such as signal-to-noise ratio and harmonic distortion as well as traditional dc specifications.

The part is available in a 24-pin, 0.3 inch wide, plastic or hermetic dual-in-line package (DIP) and in a 28-pin, plastic SOIC package.

FUNCTIONAL BLOCK DIAGRAM

PRODUCT HIGHLIGHTS

1. Complete 14-Bit I/O System.
   The AD7869 contains a 14-bit ADC with a track-and-hold amplifier and a 14-bit DAC with output amplifier. Also included are separate on-chip voltage references for the DAC and the ADC.
2. Dynamic Specifications for DSP Users.
   In addition to traditional dc specifications, the AD7869 is specified for ac parameters including signal-to-noise ratio and harmonic distortion. These parameters along with important timing parameters are tested on every device.
3. Small Package.
   The AD7869 is available in a 24-pin DIP and a 28-pin SOIC package.

AD7869—TIMING CHARACTERISTICS[1, 2] (V_{DD} = +5 V ± 5%, V_{SS} = −5 V ±5%, AGND = DGND = 0 V)

Parameter	Limit at T_{min}, T_{max} (All Versions)	Units	Conditions/Comments
ADC TIMING			
t_1	50	ns min	$\overline{CONVST}$ Pulse Width
t_2[3]	440	ns min	RCLK Cycle Time, Internal Clock
t_3	100	ns min	$\overline{RFS}$ to RCLK Falling Edge Setup Time
t_4	20	ns min	RCLK Rising Edge to $\overline{RFS}$
	100	ns max	
t_5[4]	155	ns max	RCLK to Valid Data Delay, C_L = 35 pF
t_6	4	ns min	Bus Relinquish Time after RCLK
	100	ns max	
t_{13}[5]	2 RCLK +200 to 3 RCLK + 200	ns typ	$\overline{CONVST}$ to $\overline{RFS}$ Delay
DAC TIMING			
t_7	50	ns min	$\overline{TFS}$ to TCLK Falling Edge
t_8	75	ns min	TCLK Falling Edge to $\overline{TFS}$
t_9[6]	150	ns min	TCLK Cycle Time
t_{10}	30	ns min	Data Valid to TCLK Setup Time
t_{11}	75	ns min	Data Valid to TCLK Hold Time
t_{12}	40	ns min	$\overline{LDAC}$ Pulse Width

NOTES
[1]Timing specifications are sample tested at +25°C to ensure compliance. All input signals are specified with tr = tf = 5 ns (10% to 90% of 5 V) and timed from a voltage level of 1.6 V.
[2]Serial timing is measured with a 4.7 kΩ pull-up resistor on DR and $\overline{RFS}$ and a 2 kΩ pull-up resistor on RCLK. The capacitance on all three outputs is 35 pF.
[3]When using internal clock, RCLK mark/space ratio (measured form a voltage level of 1.6 V) range is 40/60 to 60/40. For external clock, RCLK mark/space ratio = external clock mark/space ratio.
[4]DR will drive higher capacitance loads but this will add to t_s since it increases the external RC time constant (4.7 kΩ//C_L) and hence the time to reach 2.4 V.
[5]Time 2 RCLK to 3 RCLK depends on conversion start to ADC clock synchronization.
[6]TCLK mark/space ratio is 40/60 to 60/40.

ABSOLUTE MAXIMUM RATINGS*
(T_A = +25°C unless otherwise noted)

V_{DD} to AGND	−0.3 V to +7 V
V_{SS} to AGND	+0.3 V to −7 V
AGND to DGND	−0.3 V to V_{DD}+0.3 V
V_{OUT} to AGND	V_{SS} to V_{DD}
V_{IN} to AGND	V_{SS} −0.3 V to V_{DD}+0.3 V
RO ADC to AGND	−0.3 V to V_{DD}+0.3 V
RO DAC to AGND	−0.3 V to V_{DD}+0.3 V
RI DAC to AGND	−0.3 V to V_{DD}+0.3 V
Digital Inputs to DGND	−0.3 V to V_{DD}+0.3 V

Operating Temperature Range	
J Version	0°C to +70°C
A Version	−40°C to +85°C
Storage Temperature Range	−65°C to +150°C
Lead Temperature (Soldering, 10 secs)	+300°C
Power Dissipation (Any Package) to +75°C	1000 mW
Derates above +75°C by	10 mW/°C

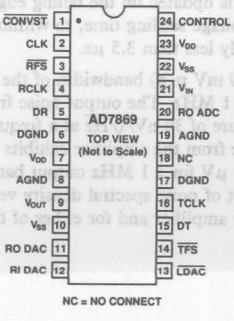
*Stresses above those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. This is a stress rating only and functional operation of the device at these or any other conditions above those listed in the operational sections of this specification is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

CAUTION

ESD (electrostatic discharge) sensitive device. The digital control inputs are diode protected; however, permanent damage may occur on unconnected devices subject to high energy electrostatic fields. Unused devices must be stored in conductive foam or shunts. The protective foam should be discharged to the destination socket before devices are inserted.

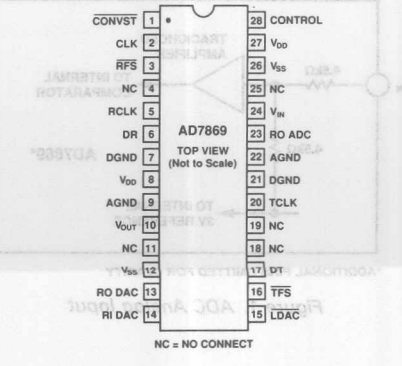
ORDERING GUIDE

Model	Temperature Range	Signal-to-Noise Ratio (SNR)	Relative Accuracy	Package Option*
AD7869JN	0°C to +70°C	78 dB	±2 LSB max	N-24
AD7869JR	0°C to +70°C	78 dB	±2 LSB max	R-28
AD7869AQ	−40°C to +85°C	77 dB	±2 LSB max	Q-24



*N = Plastic DIP; Q = Cerdip; R = Small Outline IC (SOIC). For outline information see Package Information section.

AD7869 PIN FUNCTION DESCRIPTION



DIP Pin Number	Mnemonic	Function
POWER SUPPLY		
7 & 23	V_{DD}	Positive Power Supply, 5 V ± 5%. Both V_{DD} pins must be tied together.
10 & 22	V_{SS}	Negative Power Supply, −5 V ± 5%. Both V_{SS} pins must be tied together.
8 & 19	AGND	Analog Ground. Both AGND pins must be tied together.
6 & 17	DGND	Digital Ground. Both DGND pins must be tied together.
ANALOG SIGNAL AND REFERENCE		
21	V_{IN}	ADC Analog Input. The ADC input range is ±3 V.
9	V_{OUT}	Analog Output Voltage from DAC. This output comes from a buffer amplifier. The range is bipolar, ±3 V with RI DAC = +3 V.
20	RO ADC	Voltage Reference Output. The internal ADC 3 V reference is provided at this pin. This output may be used as a reference for the DAC by connecting it to the RI DAC input. The external load capability of this reference is 500 μA.
11	RO DAC	DAC Voltage Reference Output. This is one of two internal voltage references. To operate the DAC with this internal reference, RO DAC should be connected to RI DAC. The external load capability of the reference is 500 μA.
12	RI DAC	DAC Voltage Reference Input. The voltage reference for the DAC must be applied to this pin. It is internally buffered before being applied to the DAC. The nominal reference voltage for correct operation of the AD7869 is 3 V.
ADC INTERFACE AND CONTROL		
2	CLK	Clock Input. An external TTL-compatible clock may be applied to this input. Alternatively, tying this pin to V_{SS} enables the internal laser-trimmed oscillator.
3	$\overline{RFS}$	Receive Frame Synchronization, Logic Output. This is an active low open-drain output which provides a framing pulse for serial data. An external 4.7 kΩ pull-up resistor is required on $\overline{RFS}$.
4	RCLK	Receive Clock, Logic Output. RCLK is the gated serial clock output which is derived from the internal or external ADC clock. If the CONTROL input is at V_{SS}, the clock runs continuously. With the CONTROL input at DGND the RCLK output is gated off (three-state) after serial transmission is complete. RCLK is an open-drain output and requires an external 2 kΩ pull-up resistor.
5	DR	Receive Data, Logic Output. This is an open-drain data output used in conjunction with $\overline{RFS}$ and RCLK to transmit data from the ADC. Serial data is valid on the falling edge of RCLK when $\overline{RFS}$ is low. An external 4.7 kΩ resistor is required on the DR output.
1	$\overline{CONVST}$	Convert Start, Logic Input. A low to high transition on this input puts the track-and-hold amplifier into the hold mode and starts an ADC conversion. This input is asynchronous to the CLK input.
24	CONTROL	Control, Logic Input. With this pin at 0 V, the RCLK is noncontinuous. With this pin at −5 V, the RCLK is continuous. Note, tying this pin to V_{DD} places the part in a factory test mode where normal operation is not exhibited.
DAC INTERFACE AND CONTROL		
14	$\overline{TFS}$	Transmit Frame Synchronization, Logic Input. This is a frame or synchronization signal for the DAC with serial data expected after the falling edge of this signal.
15	DT	Transmit Data, Logic Input. This is the data input which is used in conjunction with $\overline{TFS}$ and TCLK to transfer serial data to the input latch.
16	TCLK	Transmit Clock, Logic Input. Serial data bits are latched on the falling edge of TCLK when $\overline{TFS}$ is low.
13	$\overline{LDAC}$	Load DAC, Logic Input. A new word is transferred into the DAC latch from the input latch on the falling edge of this signal.
18	NC	No Connect.

PIN CONFIGURATIONS

DIP

SOIC

8

components required for normal operation are pull-up resistors for the ADC data outputs and power supply decoupling capacitors. It is comprised of a 14-bit successive approximation ADC with a track/hold amplifier, a 14-bit DAC with a buffered output and two 3 V buried Zener references, a clock oscillator and control logic.

ADC CLOCK

The AD7869 has an internal clock oscillator which can be used for the ADC conversion procedure. The oscillator is enabled by tying the CLK input to V_{SS}. The oscillator is laser trimmed at the factory to give a maximum conversion time of 10 μs. The mark/space ratio can vary from 40/60 to 60/40. Alternatively, an external TTL compatible clock may be applied to this input. The allowable mark/space ratio of an external clock is 40/60 to 60/40.

RCLK is a clock output, used for the serial interface. This output is derived directly from the ADC clock source and can be switched off at the end of conversion with the CONTROL input.

ADC CONVERSION TIMING

The conversion time for both external clock and continuous internal clock can vary from 19 to 20 rising clock edges depending on the conversion start to ADC clock synchronization. If a conversion is initiated within 30 ns prior to a rising edge of the ADC clock, the conversion time will consist of 20 rising clock edges, i.e., 9.5 μs conversion time. For noncontinuous internal clock, the conversion time always consists of 19 rising clock edges.

ADC TRACK-AND-HOLD AMPLIFIER

The track-and-hold amplifier on the analog input of the AD7869 allows the ADC to accurately convert an input sine wave of 6 V peak–peak amplitude to 14-bit accuracy. The input impedance is typically 9 kΩ, an equivalent circuit is shown in Figure 1. The input bandwidth of the track/hold amplifier is much greater than the Nyquist rate of the ADC, even when the ADC is operated at its maximum throughput rate. The 0.1 dB cut-off frequency occurs typically at 500 kHz. The track/hold amplifier acquires an input signal to 14-bit accuracy in less than 2 μs. The overall throughput rate is equal to the conversion time plus the track/hold amplifier acquisition time. For a 2.0 MHz input clock the throughput time is 12 μs max.

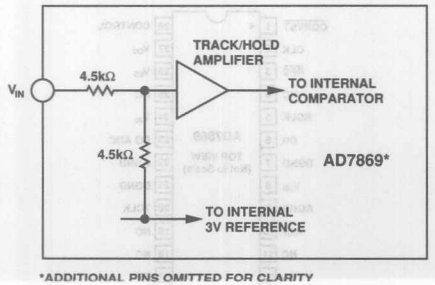


Figure 1. ADC Analog Input

mode to its hold mode at the start of conversion on the rising edge of CONVST.

INTERNAL REFERENCES

The AD7869 has two on-chip temperature compensated buried Zener references which are factory trimmed to 3 V ±10 mV. One reference provides the appropriate biasing for the ADC, while the other is available as a reference for the DAC. Both reference outputs are available (labelled RO DAC and RO ADC) and are capable of providing up to 500 μA to an external load.

The DAC input reference (RI DAC) can be sourced externally or connected to any of the two on-chip references. Applications requiring good full-scale error matching between the DAC and the ADC should use the ADC reference as shown in Figure 4.

The maximum recommended capacitance on either of the reference output pins for normal operation is 50 pF. If either of the reference outputs is required to drive a capacitive load greater than 50 pF, then a 200 Ω resistor must be placed in series with the capacitive load. The addition of decoupling capacitors, 10 μF in parallel with 0.1 μF, as shown in Figure 2 improves noise performance. The improvement in noise performance can be seen from the graph in Figure 3. Note, this applies for the DAC output only; reference decoupling components do not affect ADC performance. So, a typical application will have just the DAC reference decoupled with the other one open circuited.

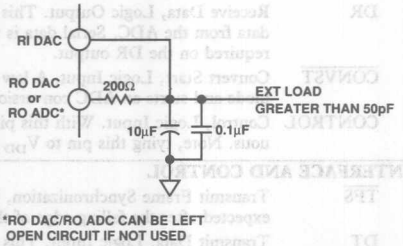

Figure 2. Reference Decoupling Components

DAC OUTPUT AMPLIFIER

The output from the voltage mode DAC is buffered by a noninverting amplifier. The buffer amplifier is capable of developing ±3 V across 2 kΩ and 100 pF load to ground and can produce 6 V peak-to-peak sine wave signals to a frequency of 20 kHz. The output is updated on the falling edge of the LDAC input. The output voltage settling time, to within 1/2 LSB of its final value, is typically less than 3.5 μs.

The small signal (200 mV p–p) bandwidth of the output buffer amplifier is typically 1 MHz. The output noise from the amplifier is low with a figure of 30 nV/$\sqrt{Hz}$ at a frequency of 1 kHz. The broadband noise from the amplifier exhibits a typical peak-to-peak figure of 150 μV for a 1 MHz output bandwidth. Figure 3 shows a typical plot of noise spectral density versus frequency for the output buffer amplifier and for either of the on-chip references.

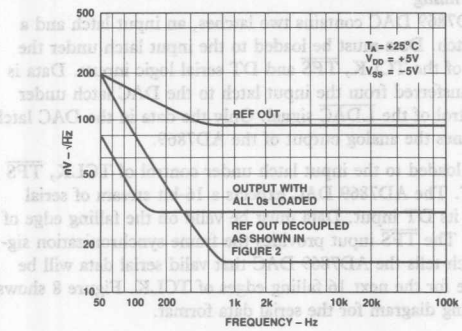

Figure 3. Noise Spectral Density vs. Frequency

INPUT/OUTPUT TRANSFER FUNCTIONS

A bipolar circuit for the AD7869 is shown in Figure 4.

The analog input/output voltage range of the AD7869 is ±3 V. The designed code transitions for the ADC occur midway between successive integer LSB values (i.e., 1/2 LSB, 3/2 LSB, 5/2 LSB . . . FS −3/2 LSBs). The input/output code is 2s Complement Binary with 1 LSB = FS/16384 = 366 μV. The ideal transfer function is shown in Figure 5.

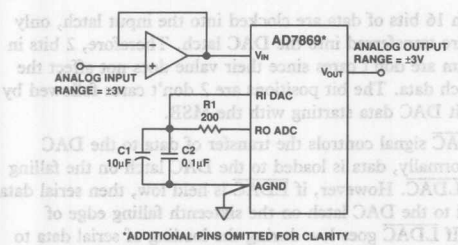

Figure 4. AD7869 Basic Bipolar Operation

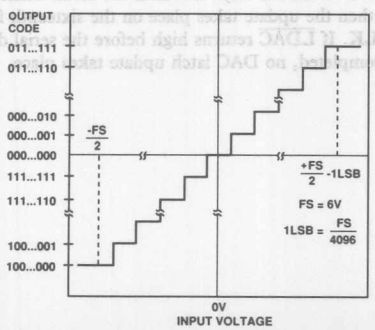

Figure 5. AD7869 Input/Output Transfer Function

OFFSET AND FULL SCALE ADJUSTMENT

In most digital signal processing (DSP) applications, offset and full-scale errors have little or no effect on system performance. Offset error can always be eliminated in the analog domain by ac coupling. Full-scale errors do not cause problems as long as the input signal is within the full dynamic range of the ADC. For applications which require that the input signal range match the full analog input dynamic range of the ADC, offset and full-scale errors have to be adjusted to zero.

ADC ADJUSTMENT

Figure 6 has signal conditioning at the input and output of the AD7869 for trimming the end points of the transfer functions of both the ADC and the DAC. Offset error must be adjusted before full-scale error. For the ADC, this is achieved by trimming the offset of A1 while the input voltage, V1, is 1/2 LSB below ground. The trim procedure is as follows: apply a voltage of −183 μV (−1/2 LSB) at V1 in Figure 6 and adjust the offset voltage of A1 until the ADC output code flickers between 11 1111 1111 1111 (3 FFF HEX) and 00 0000 0000 0000 (0000 HEX).

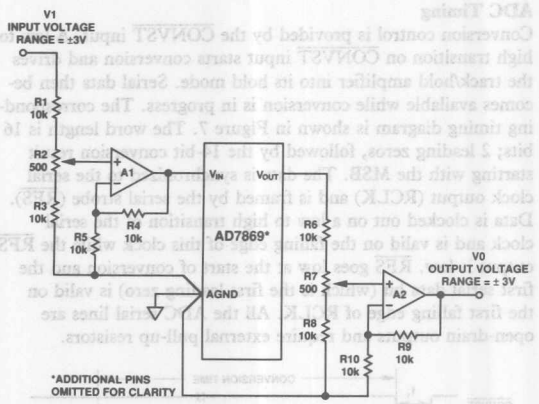

Figure 6. AD7869 with Input/Output Adjustment

ADC gain error can be adjusted at either the first code transition (ADC negative full scale) or the last code transition (ADC positive full scale). The trim procedures for both cases are as follows (see Figure 6).

ADC Positive Full-Scale Adjustment

Apply a voltage of 2.99945 V (FS/2 – 3/2 LSBs) at V1. Adjust R2 until the ADC output code flickers between 01 1111 1111 1110 (1FFE HEX) and 01 1111 1111 1111 (1FFF HEX).

ADC Negative Full-Scale Adjustment

Apply a voltage of −2.99982 V (−FS/2 + 1/2 LSB) at V1 and adjust R2 until the ADC output code flickers between 10 0000 0000 0000 (2000 HEX) and 10 0000 0000 0001 (2001 HEX).

DAC ADJUSTMENT

Op amp A2 is included in Figure 6 for the DAC transfer function adjustment. Again offset must be adjusted before full scale. To adjust offset: load the DAC with 00 0000 0000 0000 (0000 HEX) and trim the offset of A2 to 0 V. As with the ADC adjustment, gain error can be adjusted at either the first code transition (DAC negative full scale) or the last code transition (DAC positive full scale). The trim procedures for both cases are as follows:

DAC Positive Full-Scale Adjustment

Load the DAC with 01 1111 1111 1111 (1 FFF HEX) and adjust R7 until the op amp output voltage is equal to 2.99963 V, (FS/2 – 1 LSB).

DAC Negative Full-Scale Adjustment

Load the DAC with 10 0000 0000 0000 (2000 HEX) and adjust R7 until the op amp output voltage is equal to −3 V (−FS/2).

8

TIMING AND CONTROL

Communication with the AD7869 is managed by 6 dedicated pins. These consist of separate serial clocks, word framing or strobe pulses and data signals for both receiving and transmitting data. Conversion starts and DAC updating are controlled by two digital inputs; $\overline{\text{CONVST}}$ and $\overline{\text{LDAC}}$. These inputs can be asserted independently of the microprocessor by an external timer when precise sampling intervals are required. Alternatively, the $\overline{\text{LDAC}}$ and $\overline{\text{CONVST}}$ can be driven from a decoded address bus allowing the microprocessor control over conversion start and DAC updating as well as data communication to the AD7869.

ADC Timing

Conversion control is provided by the $\overline{\text{CONVST}}$ input. A low to high transition on $\overline{\text{CONVST}}$ input starts conversion and drives the track/hold amplifier into its hold mode. Serial data then becomes available while conversion is in progress. The corresponding timing diagram is shown in Figure 7. The word length is 16 bits; 2 leading zeros, followed by the 14-bit conversion result starting with the MSB. The data is synchronized to the serial clock output (RCLK) and is framed by the serial strobe ($\overline{\text{RFS}}$). Data is clocked out on a low to high transition of the serial clock and is valid on the falling edge of this clock while the $\overline{\text{RFS}}$ output is low. $\overline{\text{RFS}}$ goes low at the start of conversion and the first serial data bit (which is the first leading zero) is valid on the first falling edge of RCLK. All the ADC serial lines are open-drain outputs and require external pull-up resistors.

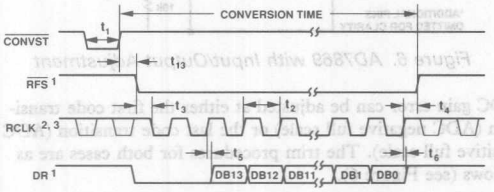

Figure 7. ADC Control Timing Diagram

The serial clock out is derived from the ADC master clock source which may be internal or external. Normally, RCLK is required during the serial transmission only. In these cases it can be shut down (i.e., placed into three-state) at the end of conversion to allow multiple ADCs to share a common serial bus. However, some serial systems (e.g., TMS32020) require a serial clock which runs continuously. Both options are available on the AD7869 ADC. With the CONTROL input at 0 V, RCLK is noncontinuous; and when it is at −5 V, RCLK is continuous.

DAC Timing

The AD7869 DAC contains two latches, an input latch and a DAC latch. Data must be loaded to the input latch under the control of the TCLK, $\overline{\text{TFS}}$ and DT serial logic inputs. Data is then transferred from the input latch to the DAC latch under the control of the $\overline{\text{LDAC}}$ signal. Only the data in the DAC latch determines the analog output of the AD7869.

Data is loaded to the input latch under control of TCLK, $\overline{\text{TFS}}$ and DT. The AD7869 DAC expects a 16-bit stream of serial data on its DT input. Data must be valid on the falling edge of TCLK. The $\overline{\text{TFS}}$ input provides the frame synchronization signal which tells the AD7869 DAC that valid serial data will be available for the next 16 falling edges of TCLK. Figure 8 shows the timing diagram for the serial data format.

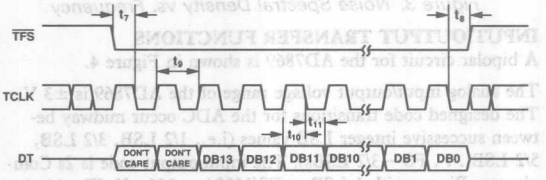

Figure 8. DAC Control Timing Diagram

Although 16 bits of data are clocked into the input latch, only 14 bits are transferred into the DAC latch. Therefore, 2 bits in the stream are don't cares since their value does not affect the DAC latch data. The bit positions are 2 don't cares followed by the 14-bit DAC data starting with the MSB.

The $\overline{\text{LDAC}}$ signal controls the transfer of data to the DAC latch. Normally, data is loaded to the DAC latch on the falling edge of $\overline{\text{LDAC}}$. However, if $\overline{\text{LDAC}}$ is held low, then serial data is loaded to the DAC latch on the sixteenth falling edge of TCLK. If $\overline{\text{LDAC}}$ goes low during the loading of serial data to the input latch, no DAC latch update takes place on the falling edge of $\overline{\text{LDAC}}$. If $\overline{\text{LDAC}}$ stays low until the serial transfer is completed, then the update takes place on the sixteenth falling edge of TCLK. If $\overline{\text{LDAC}}$ returns high before the serial data transfer is completed, no DAC latch update takes place.

AD7869 DYNAMIC SPECIFICATIONS

The AD7869 is specified and 100% tested for dynamic performance specifications as well as traditional dc specifications such as Integral and Differential Nonlinearity. These ac specifications are required for signal processing applications such as speech recognition, spectrum analysis, and high speed modems. These applications require information on the converter's effect on the spectral content of the input signal. Hence, the parameters for which the AD7869 is specified include SNR, harmonic distortion and peak harmonics. These terms are discussed in more detail in the following sections.

Signal-to-Noise Ratio (SNR)

SNR is the measured signal-to-noise ratio at the output of the ADC or DAC. The signal is the rms magnitude of the fundamental. Noise is the rms sum of all the nonfundamental signals up to half the sampling frequency ($f_{SAMPLE}/2$) excluding dc. SNR is dependent upon the number of levels used in the quantization process; the more levels, the smaller the quantization noise. The theoretical signal-to-noise ratio for a sine wave input is given by

$$SNR = (6.02N + 1.76)\ dB \quad \ldots\ldots\ldots\ldots\ldots\ldots (1)$$

where N is the number of bits. Thus for an ideal 14-bit converter, SNR = 86 dB.

Effective Number of Bits

The formula given in Equation (1) relates the SNR to the number of bits. Rewriting the formula, as in Equation (2), it is possible to get a measure of performance expressed in effective number of bits (N).

$$N = \frac{SNR - 1.76}{6.02} \quad \ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots (2)$$

The effective number of bits for a device can be calculated directly from its measured SNR.

Harmonic Distortion

Harmonic Distortion is the ratio of the rms sum of harmonics to the fundamental. For the AD7869, total harmonic distortion (THD) is defined as:

$$THD = 20\ log \frac{\sqrt{V_2^2 + V_3^2 + V_4^2 + V_5^2 + V_6^2}}{V_1}$$

where V1 is the rms amplitude of the fundamental and V2, V3, V4, V5 and V6 are the rms amplitudes of the second through to the sixth harmonic. The THD is also derived from the FFT plot of the ADC or DAC output spectrum.

ADC Testing

The output spectrum from the ADC is evaluated by applying a sine wave signal of very low distortion to the V_{IN} input while reading multiple conversion results. A Fast Fourier Transform (FFT) plot is generated from which the SNR data can be obtained. Figure 9 shows a typical 2048 point FFT plot of the AD7869AQ ADC with an input signal of 10 kHz and a sampling frequency of 60 kHz. The SNR obtained from this graph is 80 dB. It should be noted that the harmonics are taken into account when calculating the SNR.

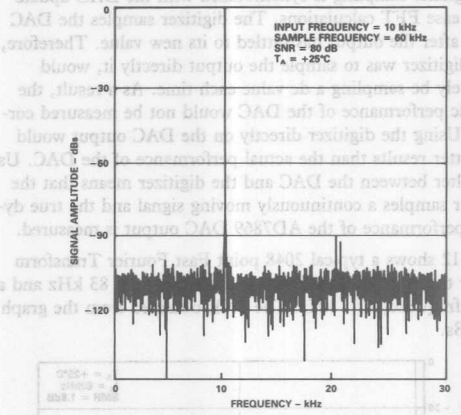

Figure 9. AD7869, ADC FFT Plot

Figure 10 shows a typical plot of effective number of bits versus frequency for an AD7869AQ with a sampling frequency of 60 kHz. The effective number of bits typically falls between 12.7 and 13.1 corresponding to SNR figures of 79 and 80.4 dB.

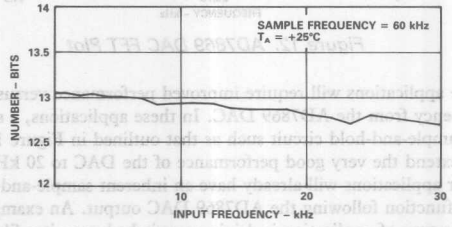

Figure 10. Effective Number of Bits vs. Frequency for the ADC

DAC Testing

A simplified diagram of the method used to test the dynamic performance specifications of the DAC is outlined in Figure 11. Data is loaded to the DAC under control of the microcontroller and associated logic. The output of the DAC is applied to a 9th order low pass filter whose cut-off frequency corresponds to the Nyquist limit. The output of the filter is in turn applied to a 16-bit accurate digitizer. This digitizes the signal and the microcontroller generates an FFT plot from which the dynamic performance of the DAC can be evaluated.

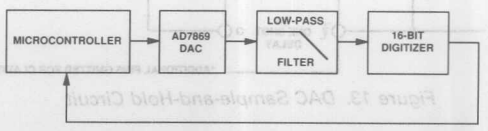

Figure 11. AD7869 DAC Dynamic Performance Test Circuit

8

rate to ease FFT calculations. The digitizer samples the DAC output after the output has settled to its new value. Therefore, if the digitizer was to sample the output directly it, would effectively be sampling a dc value each time. As a result, the dynamic performance of the DAC would not be measured correctly. Using the digitizer directly on the DAC output would give better results than the actual performance of the DAC. Using a filter between the DAC and the digitizer means that the digitizer samples a continuously moving signal and the true dynamic performance of the AD7869 DAC output is measured.

Figure 12 shows a typical 2048 point Fast Fourier Transform plot for the AD7869 DAC with an update rate of 83 kHz and an output frequency of 1 kHz. The SNR obtained from the graph is 82 dBs.

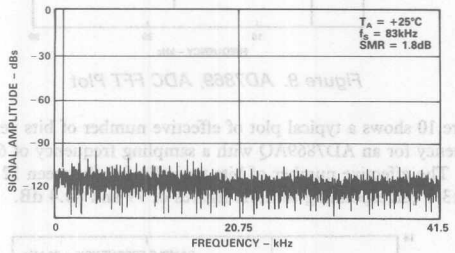

Figure 12. AD7869 DAC FFT Plot

Some applications will require improved performance versus frequency from the AD7869 DAC. In these applications, a simple sample-and-hold circuit such as that outlined in Figure 13 will extend the very good performance of the DAC to 20 kHz. Other applications will already have an inherent sample-and-hold function following the AD7869 DAC output. An example of this type of application is driving a switched capacitor filter where the updating of the DAC is synchronized with the switched capacitor filter. This inherent sample-and-hold function also extends the frequency range performance.

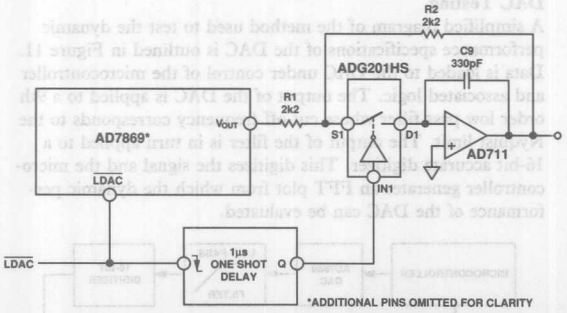

Figure 13. DAC Sample-and-Hold Circuit

The typical performance plots of Figures 14 and 15 show the AD7869 DAC performance over a wide range of input frequencies at an update rate of 83 kHz. The plot of Figure 14 is without a sample-and-hold on the DAC output while the plot of Figure 15 is generated with a sample-and-hold on the output.

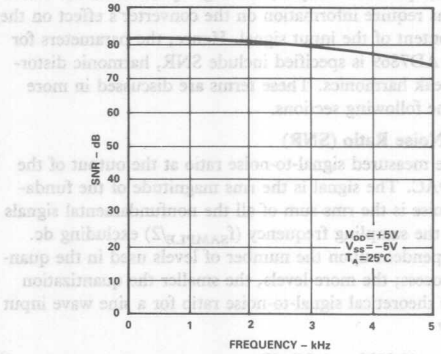

Figure 14. DAC Performance vs. Frequency (No Sample-and-Hold)

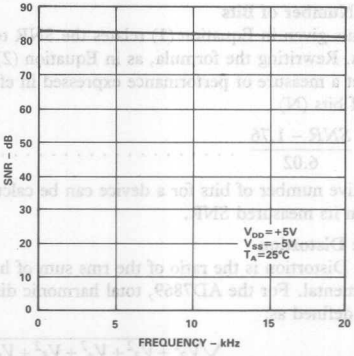

Figure 15. DAC Performance vs. Frequency (Sample-and-Hold)

MICROPROCESSOR INTERFACING

Microprocessor interfacing to the AD7869 is via a serial bus that uses standard protocol compatible with DSP machines. The communication interface consists of separate transmit (DAC) and receive (ADC) sections whose operations can be either synchronous or asynchronous with respect to each other. Each section has a clock signal, a data signal and a frame or strobe pulse. Synchronous operation means that data is transmitted from the ADC and to the DAC at the same time. In this mode only one interface clock is needed, and this has to be the ADC clock out, so RCLK must be connected to TCLK. For asynchronous operation, DAC and ADC data transfers are independent of each other, the ADC provides the receive clock (RCLK) while the transmit clock (TCLK) may be provided by the processor or the ADC or some other external clock source.

Another option to be considered with serial interfacing is the use of a gated clock. A gated clock means that the device that is sending the data switches on the clock when data is ready to be transmitted and three states the clock output when transmission is complete. Only 16 clock pulses are transmitted with the first data bit getting latched into the receiving device on the first falling clock edge. Ideally, there is no need for frame pulses, however, the AD7869 DAC frame input ($\overline{TFS}$) has to be driven high between data transmissions. The easiest method is to use RFS to drive $\overline{TFS}$ and use only synchronous interfacing. This avoids the use of interconnects between the processor and AD7869 frame signals. Not all processors have a gated clock facility, Figure 16 shows an example with the DSP56000.

Table I below shows the number of interconnect lines between the processor and the AD7869 for the different interfacing options.

The AD7869 has the facility to use different clocks for transmitting and receiving data. This option, however, only exists on some processors and normally just one clock (ADC clock) is used for all communication with the AD7869. For simplicity, all the interface examples in this data sheet use synchronous interfacing and use the ADC clock (RCLK) as an input for the DAC clock (TCLK). For a better understanding of each of these interfaces, consult the relevant processor data sheet.

Configuration	Number of Interconnects	Signals
Synchronous	4	RCLK, DR, DT and $\overline{RFS}$ ($TCLK = RCLK$, $\overline{TFS} = \overline{RFS}$)
Asynchronous*	5 or 6	RCLK, DR, $\overline{RFS}$, DT, $\overline{TFS}$ ($TCLK = RCLK$ or μP serial CLK)
Synchronous Gated Clock	3	RCLK, DR and DT ($TCLK = RCLK$, $\overline{TFS} = \overline{RFS}$)

*5 LINES OF INTERCONNECT WHEN TCLK = RCLK
6 LINES OF INTERCONNECT WHEN TCLK = µP SERIAL CLK

Table I. Interconnect Lines for Different Interfacing Options

AD7869–DSP 56000 Interface

Figure 16 shows a typical interface between the AD7869 and DSP56000. The interface arrangement is synchronous with a gated clock requiring only three lines of interconnect. The DSP56000 internal serial control registers have to be configured for a 16-bit data word with valid data on the first falling clock edge. Conversion starts and DAC updating are controlled by an external timer. Data transfers, which occur during ADC conversions are between the processor receive and transmit shift registers and the AD7869's ADC and DAC. At the end of each 16-bit transfer the DSP56000 receives an internal interrupt indicating the transmit register is empty and the receive register is full.

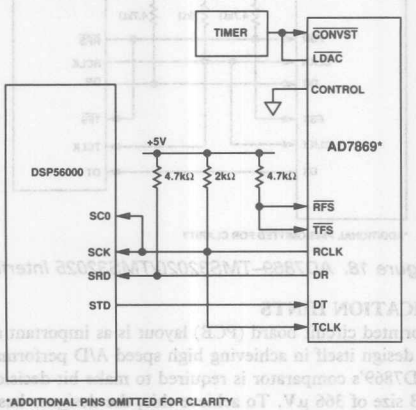

Figure 16. AD7869–DSP56000 Interface

AD7869–ADSP-2101/2102 Interface

An interface which is suitable for the ADSP-2101 or the ADSP-2102 is shown in Figure 17. The interface is configured for synchronous, continuous clock operation. The $\overline{LDAC}$ is tied low so the DAC gets updated on the sixteenth falling clock after $\overline{TFS}$ goes low. Alternatively, $\overline{LDAC}$ may be driven from a timer as shown in Figure 16. As with the previous interface the processor receives an interrupt after reading or writing to the AD7869 and updates its own internal registers in preparation for the next data transfer.

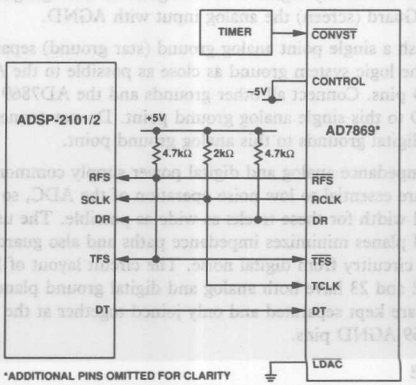

Figure 17. AD7869–ADSP-2101/ADSP-2102 Interface

8

AD7869 – TMS32020 Interface

Figure 18 shows an interface which is suitable for the TMS32020/TMS320C25 processors. This interface is configured for synchronous, continuous clock operation. Note, the AD7869 will not interface correctly to these processors if the AD7869 is configured for a noncontinuous clock. Conversion starts and DAC updating are controlled by an external timer.

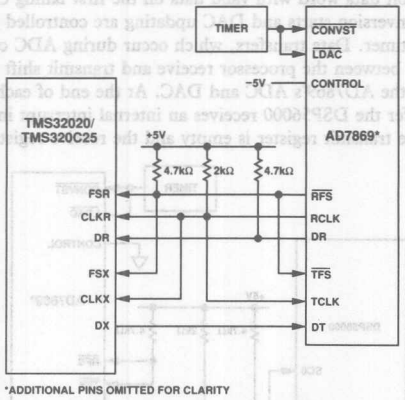

Figure 18. AD7869–TMS32020/TMS32025 Interface

APPLICATION HINTS

Good printed circuit board (PCB) layout is as important as the circuit design itself in achieving high speed A/D performance. The AD7869's comparator is required to make bit decisions on an LSB size of 366 μV. To achieve this, the designer has to be conscious of noise both in the ADC itself and in the preceding analog circuitry. Switching mode power supplies are not recommended as the switching spikes will feed through to the comparator causing noisy code transitions. Other causes of concern are ground loops and digital feedthrough from microprocessors. These are factors which influence any ADC, and a proper PCB layout which minimizes these effects is essential for best performance.

LAYOUT HINTS

Ensure that the layout for the printed circuit board has the digital and analog signal lines separated as much as possible. Take care not to run any digital track alongside an analog signal track. Guard (screen) the analog input with AGND.

Establish a single point analog ground (star ground) separate from the logic system ground as close as possible to the AD7869 AGND pins. Connect all other grounds and the AD7869 DGND to this single analog ground point. Do not connect any other digital grounds to this analog ground point.

Low impedance analog and digital power supply common returns are essential to low noise operation of the ADC, so make the foil width for these tracks as wide as possible. The use of ground planes minimizes impedance paths and also guards the analog circuitry from digital noise. The circuit layout of Figures 22 and 23 have both analog and digital ground planes which are kept separated and only joined together at the AD7869 AGND pins.

NOISE

Keep the input signal leads to V_{IN} and signal return leads from AGND as short as possible to minimize input noise coupling. In applications where this is not possible, use a shielded cable between the source and the ADC. Reduce the ground circuit impedance as much as possible since any potential difference in grounds between the signal source and the ADC appears as an error voltage in series with the input signal.

INPUT/OUTPUT BOARD

Figure 19 shows an analog I/O board based on the AD7869. The corresponding printed circuit (PC) board layout and silkscreen are shown in Figures 21 to 23.

The analog input to the AD7869 is buffered with an AD711 op amp. There is a component grid provided near the analog input on the PC board which may be used for an antialiasing filter for the ADC or a reconstruction filter for the DAC or any other conditioning circuitry. To facilitate this option, there are two wire links (labeled LK1 and LK2) required on the analog input and output tracks.

The board contains a SHA circuit which can be used on the output of the AD7869 DAC to extend the very good performance of the part over a wider frequency range. The increased performance from the SHA can be seen from Figures 14 and 15 of this data sheet. A wire link (labeled LK3) connects the board output to either the SHA output or directly to the AD7869 DAC output .

There are three $\overline{\text{LDAC}}$ link options on the board; $\overline{\text{LDAC}}$ can be driven from an external source independent of $\overline{\text{CONVST}}$, $\overline{\text{LDAC}}$ can be tied to $\overline{\text{CONVST}}$ or $\overline{\text{LDAC}}$ can be tied to GND. Choosing the latter option of tying $\overline{\text{LDAC}}$ to GND disables the SHA operation, and places the SHA permanently in the track mode.

Microprocessor connections to the board are made by a 9-way D-type connector. The pinout is shown in Figure 20. The ADC's digital outputs are buffered with 74HC4050s. These buffers provide a higher current output capability for high capacitance loads or cables. Normally, these buffers are not required as the AD7869 will be sitting on the same board as the processor.

POWER SUPPLY CONNECTIONS

The PC board requires two analog power supplies and one 5 V digital supply. Connections to the analog supply are made directly to the PC board as shown on the silkscreen in Figure 21. The connections are labeled V+ and V− and the range for both of these supplies is 12 V to 15 V. Connections to the 5 V digital supply are made through the D-type connector SKT6. The ± 5 V analog supply required by the AD7869 are generated from two voltage regulators on the V+ and V− supplies.

WIRE LINK OPTIONS

LK1, Analog Input Link

LK1 connects the analog input to a component grid or to a buffer amplifier which drives the ADC input.

LK2, Analog Output Link

LK2 connects the analog output to the component grid or to either the SHA or DAC output (see LK3).

LK3, SHA or DAC Select

The analog output may be taken directly from the DAC or from a SHA at the output of the DAC.

LK4, DAC Reference Selection

The DAC reference may be connected to either the ADC reference output (RO ADC) or to the DAC reference (RO DAC).

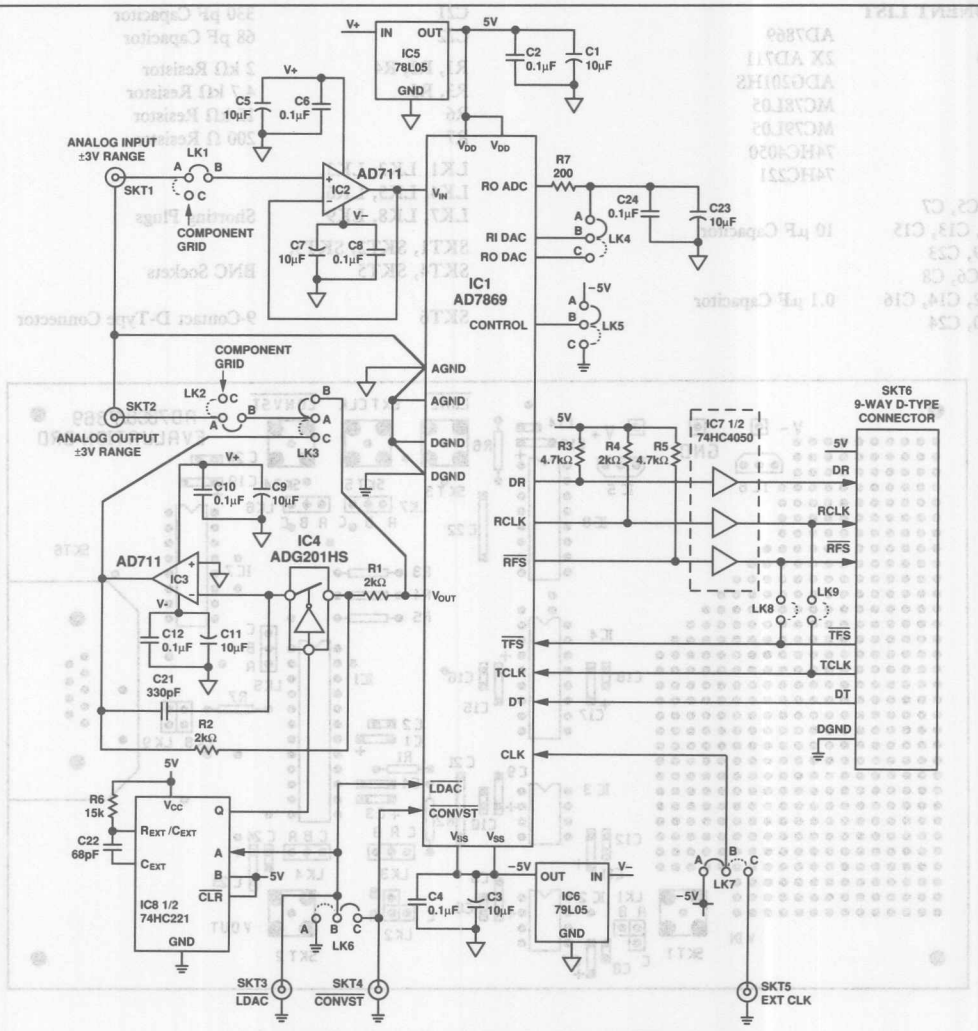

Figure 19. Input/Output Circuit Based on the AD7869

LK5, ADC Internal Clock Selection
This link configures the ADC for continuous or noncontinuous internal clock operation.

LK6, DAC Updating
The DAC, $\overline{\text{LDAC}}$ input may asserted independently of the ADC $\overline{\text{CONVST}}$ signal or it may be tied to $\overline{\text{CONVST}}$ or it may tied to GND.

LK7, ADC Clock Source
This link provides the option for the ADC to use its own internal clock oscillator or an external TTL compatible clock.

LK8 Frame Synchronous Option
LK8 provides the option of tying the ADC $\overline{\text{RFS}}$ output to the DAC $\overline{\text{TFS}}$ input.

LK9 Transmit/Receive Clock Option
LK9 provides the option to connect the ADC RCLK to the DAC TCLK.

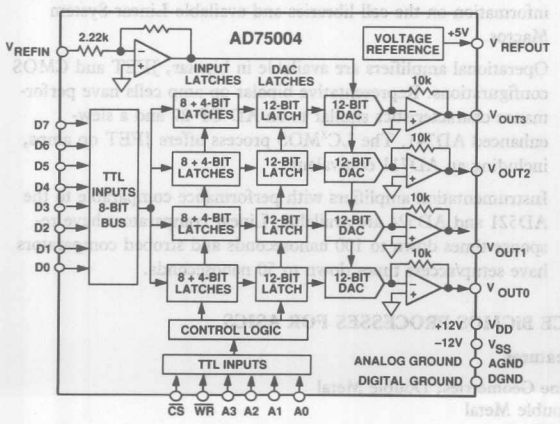
Mixed-Signal Application Specific Integrated Circuits

Analog Devices offers a full spectrum of signal conditioning and conversion capabilities in mixed-signal application specific integrated circuits (ASICs). These chip-level systems can implement combined analog/digital designs with 10- to 14-bit accuracy and 12- to 20-bit resolution that formerly required board-level solutions. Combined with our general purpose DSPs from the ADSP-2100 and ADSP-21000 families, our ASICs can provide custom two-chip solutions to meet complex system requirements.

Analog Devices can incorporate most of the functions of its standard monolithic linear and converter parts in full-custom and semicustom ICs. Full-custom parts optimize performance and space requirements, while cell-based semicustom parts reduce development time and engineering expense. Development costs can be cut further by tailoring a predefined system-on-a-chip known as a Linear System Macro to your application.

Analog's experienced design engineers work with powerful computer-aided design tools to design and lay out your circuit. Design centers are currently in Massachusetts, England and Ireland.

Multiple locations for fabrication, assembly and testing ensure a ready supply of production parts. Products can be processed in our MIL-38510 certified facilities.

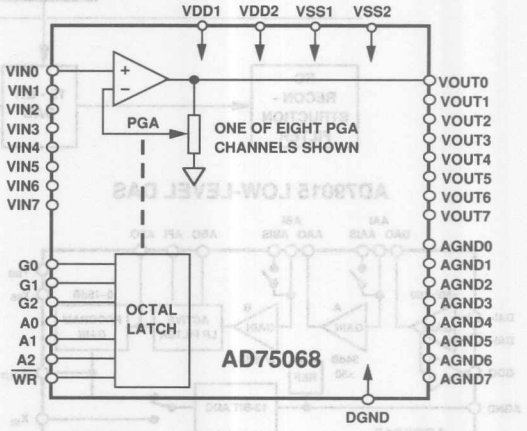


DESIGN EXAMPLES

Analog Devices has created a variety of customer-specific and function-specific ASIC parts. Described here are three Linear System Macros, a custom chipset and a semicustom chip.

AD75004 Quad DAC

This circuit contains four separate 12-bit D/A converters with amplifiers for voltage output and an on-board reference. Double-buffering latches interface with an 8-bit parallel bus and permit updating of all four channels individually or simultaneously. Outputs swing ±5 V, drive ±5 mA, and settle within 4 μs.



AD75004 QUAD DAC

AD75068 Octal Programmable Gain Amplifier

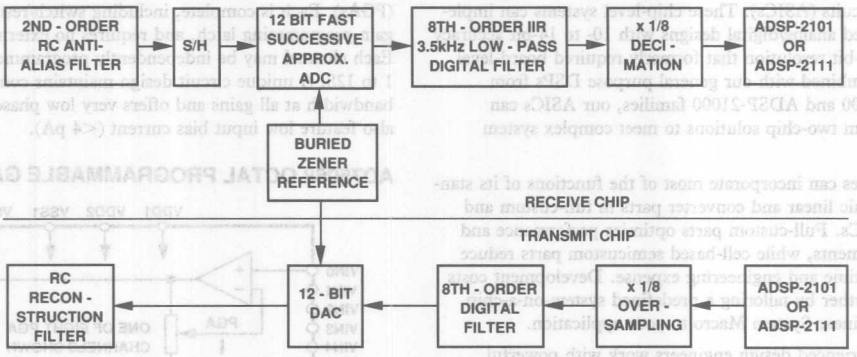
The AD75068 contains eight programmable gain amplifiers (PGAs). Each is complete, including switch/resistor network and gain programming latch, and requires no external components. Each channel may be independently programmed for gains from 1 to 128. A unique circuit design maintains constant 2 MHz bandwidth at all gains and offers very low phase shift; the PGAs also feature low input bias current (<4 pA).

AD75068 OCTAL PROGRAMMABLE GAIN AMPLIFIER

Derivative Circuits

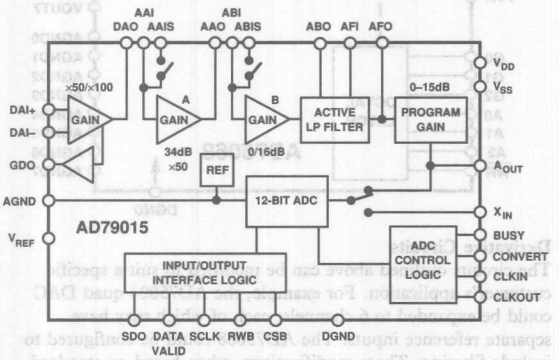
The circuits outlined above can be modified to suit a specific customer's application. For example, the AD75004 quad DAC could be expanded to 6 channels, each of which may have separate reference inputs. The AD75068 could be configured to include filtering. These modifications, when based on standard library cells, can provide the fastest, most cost effective semicustom solution.

Modem Chipset



Library cells can be combined to form macro building blocks for high speed modems. This two-chip design concept filters and converts data to interface an Analog Devices digital signal processor with the analog circuitry of a 9600-baud modem. On one chip, the received signal passes through an antialiasing filter, sample-and-hold, 12-bit A/D converter, 8th-order digital filter and decimation. On the other chip, transmit data is 8 × oversampled, then goes to an 8th-order filter, a 12-bit DAC and an active reconstruction filter.

AD79015 Low Level DAS



This circuit is a complete data acquisition system for low level signals (e.g., ECG and EEG) with a throughput of 10,000 samples per second. It provides high accuracy, high stability and functional completeness in a small 28-pin PLCC package. It includes a high performance instrumentation amp, low-pass and band-pass filters, and a 12-bit ADC with on-chip reference. It also includes a fast 8/12-bit serial port to interface to most microprocessor systems.

HIGH SPEED MODEM CHIPSET

AD79015 LOW-LEVEL DAS

HIGH PERFORMANCE PROCESSES

Analog Devices' semicustom and custom circuits are fabricated using the same high performance processes as our standard-product ICs. These mixed bipolar-CMOS processes include thin-film resistors which may be laser trimmed for precise matching and provide stable performance over a wide temperature range.

The ABCMOS, BiMOS II, and Linear Compatible CMOS (LC^2MOS) processes combine bipolar and CMOS devices on one chip. Functional density is an order of magnitude greater than previous mixed-signal processes; over 40,000 devices can be placed on a single chip. Bipolar transistors provide low noise, low offset input stages and moderate power output stages. The CMOS devices offer high input impedance, and make dense logic and analog switches for data converters, multiplexers and switched-capacitor filters. LC^2MOS also provides a JFET for very low noise amplifiers, and a low-noise buried-Zener reference. ABCMOS represents the next generation in a combined bipolar/CMOS process for mixed-signal applications.

The bipolar-CMOS processes operate on supply voltages ranging from single +5 V to split ±15V, with signal levels ranging from single-ended +3 V to ±10 V. These processes are ideally suited for applications in avionics, instrumentation, industrial automation, computers and peripherals, and telecommunications.

The following table summarizes the processes available for designing ASICs. Other processes in development will offer even higher speed, denser logic and higher integration of analog and digital functions.

CELL LIBRARIES

Cell libraries for the bipolar/CMOS processes are described below. These libraries are growing with the development of new processes, macrocells and cells. Many new catalog parts will also be available as cells. Your local sales office can give you current information on the cell libraries and available Linear System Macros.

Operational amplifiers are available in bipolar, JFET and CMOS configurations. Representative bipolar op amp cells have performance characteristics similar to an AD OP-27 and a slew-enhanced AD741. The LC^2MOS process offers JFET op amps, including an AD711 equivalent.

Instrumentation amplifiers with performance comparable to the AD521 and AD524 are available. Linear comparators have response times down to 100 nanoseconds and strobed comparators have setup/access times down to 50 nanoseconds.

ANALOG DEVICES HIGH PERFORMANCE BiCMOS PROCESSES FOR ASICS

Process	Power	Signal	Features
ABCMOS	+5 V to ±5 V	+3 V to ±3 V	Fine Geometries; Double Metal
BiMOS II	±5 V to ±12 V	±3 V to ±10 V	Double Metal
LC^2MOS	+5 V to ±15 V	+3 V to ±10 V	JFET, Zener
LC^2MOS 2	+5 V to ±5 V	+3 V to ±3 V	Fine Geometries; Poly-Poly Capacitors, JFET, Zener

Digital-to-analog converters range in resolution from 8 to 16 bits, and include cells similar to the AD667 and AD1856. Analog-to-digital converters vary from 8 to 16 bits in resolution, and include cells equivalent to the AD7871 and AD674.

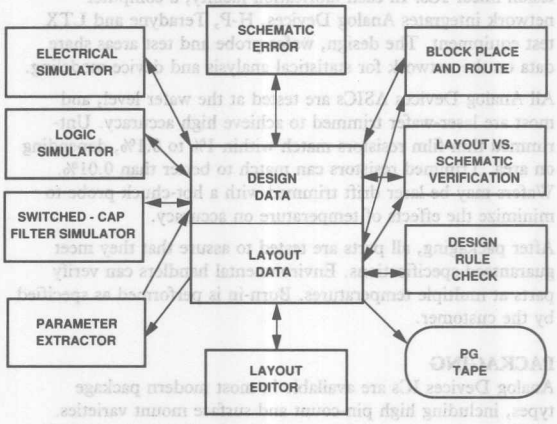
Support cells include sample-and-hold amplifiers with performance comparable to the AD585, low-voltage bandgap references comparable to the AD584, and low-noise buried Zener references.

RC active filters and programmable switched-capacitor filters are available with specifications in these ranges:

Topology: all classical filter types
Frequency Range: 200 Hz to 20 kHz (switched-cap) or 100 Hz to 1 MHz (RC)
Number of Sections: up to 10th-order (switched-cap) or 4th-order (RC)
Signal/Noise and THD: >75 dB, compatible with 12-bit data acquisition.

Logic cells include gates, counters, registers, microsequencer, PLA, RAM and ROM. Interface cells include 8-bit and 16-bit parallel I/O ports as well as synchronous serial ports and UARTs.

COMPUTER-AIDED DESIGN TOOLS



Designing a high performance mixed-signal IC is inherently more difficult than designing a gate array. The variety of analog and digital functions requires a cell-based approach. However, the use of powerful tools gives high confidence of functionality at first silicon through thorough simulation and layout verification. Complete computer-generated documentation of all schematics and analog and logic simulation waveforms permits thorough evaluation of Analog's design by your design staff before signoff for final layout and fabrication.

The overall work flow through the CAD environment follows. Key to meeting the special challenges of mixed analog/digital circuitry are the simulation and auto-layout tools, and the unification of design and layout information in a single database. Analog Devices has developed a suite of proprietary computer-aided design tools, called JANUS™, to address these issues and to implement turn-key designs.

The JANUS schematic editor offers numerous time-saving techniques and provides for specification of such data as wire widths, routing layers and routing priorities. It automatically generates a net list used by subsequent tools.

Analog uses several simulators, including electrical, logic and behavioral types. ADICE, a proprietary enhanced version of the SPICE electrical simulator, gives precision simulation of critical analog sections. It uses Newton-Raphson methods to iteratively solve nonlinear time-dependent simultaneous differential equations. It is efficient for circuits up to about 250 active devices and is used for the frequency domain or transient analysis of analog cells such as op amps, or sensitive digital cells such as dynamic RAM.

COMPUTER-AIDED DESIGN FLOW

Event-driven simulators handle larger circuits, with thousands of devices, and are typically used to simulate logic. The JANUS mixed-signal simulator combines an event-driven simulator with Newton-Raphson methods. It dynamically partitions the circuit to apply the faster event-driven techniques where possible, and the matrix methods where necessary. It also dynamically sizes the matrix and time steps to speed simulation further. The simulator can operate at the transistor level or use behavioral models, or both at the same time, allowing trade-offs between accuracy and speed.

For layout, the challenge is to increase automation while accommodating the layout sensitivity of analog circuitry. Device generators exist for the full range of active and passive devices available in the technology to automatically create a physical representation of the circuit schematic. This layout may be optimized through conventional interactive polygon-pushing.

The JANUS routing editor is driven by the connectivity of the schematics, but allows great freedom to manually control the routing of critical analog signal paths or power/ground lines while autorouting noncritical nets and spacing the layout to achieve automatic enforcement of layout rules. The JANUS routing editor uses up to three interconnect levels, and will automatically expand and compact placement as necessary to achieve 100% routing.

Finally, industry-standard layout verification tools assure conformance of the layout to both the schematic and design rules to give high confidence of functionality in first silicon. The CAD tool suite communicates via industry-standard stream formats to external databases and pattern generators.

JANUS is a trademark of Analog Devices, Inc.

TEST AND TRIM

Analog Devices has over 20 years of experience in testing complex circuits and manufactures commercial test systems for precision linear ICs. In each fabrication facility, a computer network integrates Analog Devices, H-P, Teradyne and LTX test equipment. The design, wafer probe and test areas share data on the network for statistical analysis and device modeling.

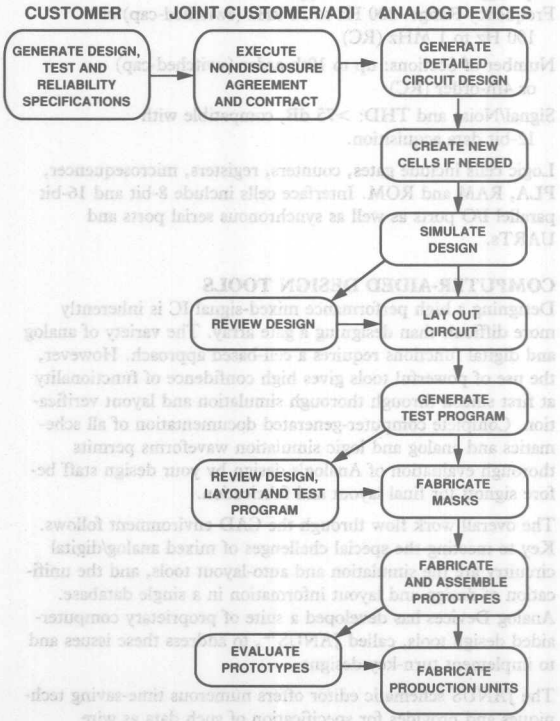
All Analog Devices ASICs are tested at the wafer level, and most are laser-wafer trimmed to achieve high accuracy. Untrimmed thin-film resistors match within 1% to 0.1%, depending on area. Trimmed resistors can match to better than 0.01%. Wafers may be laser drift trimmed with a hot-chuck probe to minimize the effects of temperature on accuracy.

After packaging, all parts are tested to assure that they meet guaranteed specifications. Environmental handlers can verify parts at multiple temperatures. Burn-in is performed as specified by the customer.

PACKAGING

Analog Devices ICs are available in most modern package types, including high pin-count and surface mount varieties. ASICs may be assembled in any of Analog Devices' standard packages, listed below. This list is constantly expanded and other packages may be used if they are suitable for high performance applications.

Available Packages



Pin Grid Array (PGA): 68 to 144 pins
Leaded Ceramic Chip Carrier (LDCC): 44 pins
Plastic Quad Flat Pack (PQFP): 44 to 132 pins
Plastic Leaded Chip Carrier (PLCC): 20 to 68 pins
Plastic Dual Inline Package (DIP): 14 to 64 pins
Side-Brazed DIP: 14 to 64 pins
Frit-Seal DIP (Cerdip): 14 to 40 pins
Small Outline (SO): 14 to 28 pins
Ceramic Quad Flat Pack (CQFP): 80 to 104 leads

PROGRAM RESPONSIBILITIES AND INTERFACES

The following figure shows the major phases in developing an ASIC and responsibilities during each phase. The overall development time depends on the complexity of the circuit and on how custom the design is.

Your Analog Devices Sales Engineer is your first interface for ASIC development. Your local sales office can provide further information on Analog Devices' custom/semicustom capabilities.

PROGRAM RESPONSIBILITIES AND INTERFACES

GENERAL DESCRIPTION

Analog Devices offers a broad line of modular ac/dc power supplies that provide both OEMs and designers a reliable, easy to use, low-cost solution to their power requirements. Models are available in PC mountable and chassis mountable designs with 5 volt to 15 volt (single, dual, triple) outputs and current ratings from 25 mA to 5 amps. Since these modular supplies are fully encapsulated, no trimming or external component selection is necessary; simply mount the unit, connect power and output leads, and you're on the air! Most Analog Devices' power supplies are available from stock in both large and small quantities with substantial discounts being applied to large quantity orders.

AC/DC POWER SUPPLY FEATURES

- Current Limit Short Circuit Protection
- PC Mounted and Chassis Mounted Versions
- Single (+5 V), Dual (±12 V, ±15 V), and Triple (±15 V/+5 V, ±15 V/+1 V to +15 V) Output Supplies
- Current Outputs:
  25 mA to 1000 mA for Dual and Triple Output Supplies
  250 mA to 5000 mA for Single Output Supplies
- Wide Input Voltage Range
- Low Output Ripple and Noise
- Excellent Line & Load Regulation Characteristics
- High Temperature Stability
- Free-Air Convection Cooling; No External Heat Sink Required

GENERAL SPECIFICATIONS

Power Requirements
- Input Voltage Range: 105 V ac to 125 V ac
- Frequency: 50 Hz to 250 Hz

Electrical Specifications
- Temperature Coefficient: 0.02%/°C
- Output Voltage Accuracy: ±2%, max
  See Specifications Table
- Breakdown Voltage: 500 V rms, min
- Isolation Resistance: 50 MΩ
- Short Circuit Protection: All ac/dc power supplies employ current limiting. They can withstand substantial overload including direct short. Prolonged operation should be avoided since excessive temperature rises will occur.

Environmental Requirements
- Operating Temperature Range: −25°C to +71°C
- Storage Temperature Range: −25°C to +85°C

SPECIFICATIONS – Typical @ +25°C and 115 V ac 60 Hz unless otherwise noted*

Power Supplies
Modular DC/DC Converters

GENERAL DESCRIPTION

Analog Devices' line of compact dc/dc converters offers system designers a means of supplying a reliable, easy to use, low cost solution to a variety of floating (analog and digital) power applications. These devices provide high accuracy, short circuit protected, regulated outputs with very low output noise and ripple characteristics.

Fourteen models are offered in five power levels of 1 watt, 1.8 watts, 4.5 watts, 6 watts and 12 watts. Input voltage versions include 5 volt, 12 volt, 24 volt and 28 volt with output ranges as follows: +5 volt, ±12 volts and ±15 volts at ±60 mA to 1000 mA output current capability.

Most models are high efficiency (typically over 60% at full load) and feature complete 6-sided continuous shielding for EMI/RFI protection. A π-type input filter is contained, in some models, which virtually eliminates the effects of reflected input ripple current. Most Analog Devices' dc/dc converters are available from stock in both large and small quantities with substantial discounts being applied to large quantity orders.

DC/DC POWER SUPPLY FEATURES

- Inaudible (>20 kHz) Converter Switching Frequency
- Continuous, Six-Sided EMI/RFI Shielding Except on 1 Watt and 1.8 Watt Models
- Output Short Circuit Protection (Either Output to Common)
- Automatic Restart After Short Condition Removed
- Automatic Starting with Reverse Current Injected into Outputs
- Low Output Ripple and Noise
- High Temperature Stability
- Free Air Convection Cooling
  No external heat sink or specification derating is required over the operating temperature range.

GENERAL SPECIFICATIONS FOR 1 W AND 1.8 W MODELS

Line Regulation – Full Range: ±0.3% (±1% max, 949)
Load Regulation – No Load to Full Load: ±0.4% (±0.5% max, 949)
Output Noise and Ripple: 20 mV p-p (with 15 µF tantalum capacitor across each output) 2 mV rms max, 949)
Breakdown Voltage: 300 V dc min (500 V dc min, 949)
Input Filter Type: π
Operating Temperature Range: −25°C to +71°C
Storage Temperature Range: −40°C to +125°C (+100°C, 949)
Fusing: If input fusing is desired, we recommend the use of a slow blow type fuse that is rated at 150%–200% of the dc/dc converter's full load input current.

GENERAL SPECIFICATIONS FOR 4.5 W, 6 W AND 12 W MODELS

Line Regulation – Full Range: ±0.07% max (±0.02% max, 951, 960 Series) (±0.1% max, 943)
Load Regulation – No Load to Full Load: ±0.07% max (±0.02% max, 951, 960 Series) (±0.1% max, 943)
Output Noise and Ripple: 1 mV rms max
Breakdown Voltage: 500 V dc min
Input Filter Type: π
Operating Temperature Range: −25°C to +71°C
Storage Temperature Range: −40°C to +125°C
Fusing: If input fusing is desired, we recommend the use of a slow blow type fuse that is rated at 150%–200% of the dc/dc converter's full load input current.

SPECIFICATIONS – Typical @ +25°C at nominal input voltage unless otherwise noted*

NOTES
[1]Models 940 and 941 will deliver up to 120 mA output current (and Model 943 will deliver up to 600 mA) over an input voltage range of 4.65 V dc and 5.5 V dc.
*Consult Analog Devices Power Supplies Catalog for additional information.
**Single-ended or unbalanced operation is permissible such that total output current load does not exceed a total of 120 mA.
Specifications subject to change without notice.

NOTES

1. Index area; a notch or a lead one identification mark is located adjacent to lead one.
2. The minimum limit for dimension b_1 may be 0.023" (0.58mm) for all four corner leads only.
3. Dimension Q shall be measured from the seating plane to the base plane.
4. This dimension allows for off-center lid, meniscus and glass overrun.
5. Applies to all four corners.
6. All leads – increase maximum limit by 0.003" (0.08mm) measured at the center of the flat, when hot solder dip lead finish is applied.
7. Fourteen spaces.

NOTES

1. Index area; a notch or a lead one identification mark is located adjacent to lead one.
2. The minimum limit for dimension b_1 may be 0.023″ (0.58 mm) for all four corner leads only.
3. Dimension Q shall be measured from the seating plane to the base plane.
4. The basic pin spacing is 0.100″ (2.54 mm) between centerlines.
5. Applies to all four corners.
6. E_1 shall be measured at the centerline of the leads.
7. Twenty-two spaces.

NOTES
1. Index area; a notch or a lead one identification mark is located adjacent to lead one.
2. The minimum limit for dimension b_1 may be 0.023" (0.58mm) for all four corner leads only.
3. Dimension Q shall be measured from the seating plane to the base plane.
4. This dimension allows for off-center lid, meniscus and glass overrun.
5. Applies to all four corners.
6. Lead center when α is 0°. E_1 shall be measured at the centerline of the leads.
7. All leads – increase maximum limit by 0.003"(0.08mm) measured at the center of the flat, when hot solder dip lead finish is applied.
8. Six spaces.

Ordering Guide

INTRODUCTION

This Ordering Guide should make it easy to order Analog Devices products, whether you're buying one IC op amp, a multioption subsystem, or 1000 each of 15 different items. It will help you:

1. Find the correct part number for the options you want.
2. Get a price quotation and place an order with us.
3. Know our warranty for components and subsystems.

For answers to further questions, call the nearest sales office (listed at the back of the book) or our main office in Norwood, Mass. U.S.A. (617-329-4700).

MODEL NUMBERING

In this reference manual many of the data sheets for products having a number of standard options contain an Ordering Guide. Use it to specify the correct part number for the exact combination of options you want. Two model numbering schemes are used by Analog Devices. The first model numbering scheme is used for designating standard Analog Devices monolithic and hybrid products. The second scheme is used by our Precision Monolithics Division (formerly PMI) as designators for its product line.

Figure 1 shows the form of model number used for our proprietary standard monolithic ICs and many of our hybrids. It consists of an "AD" (Analog Devices) prefix, a 3-to-5-digit number*, an alphabetic performance/temperature-range designator and a package designator. One or two additional letters may immediately follow the digits ("A" for second-generation redesigned ICs, "DI" for dielectrically isolated CMOS switches, e.g., AD536AJH, AD7512DIKD).

Figure 2 shows a different numbering scheme used by our Precision Monolithics Division. This numbering scheme starts with a prefix which designates the device type and model number. It is then followed by a suffix consisting of alphabetic designators (as applicable) to indicate additional functional designations or options and packaging options.

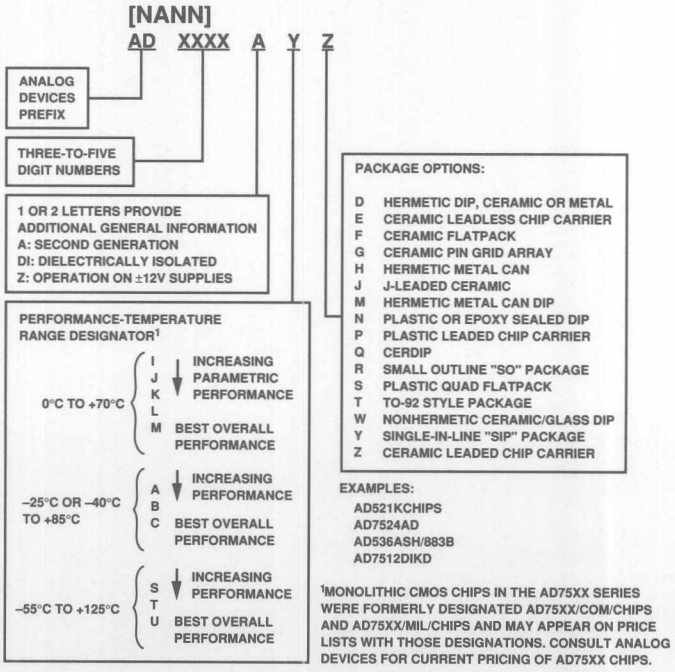

Figure 1. Model-Number Designations for Standard Analog Devices Monolithic and Hybrid IC Products. S, T and U Grades have the Added Suffix, /883B for Devices that Qualify to the Latest Revision of MIL-STD-883, Level B.

***For some models, the combination [digit][letter][two or three digits] is used instead of ADXXXX, e.g., 2S80.**

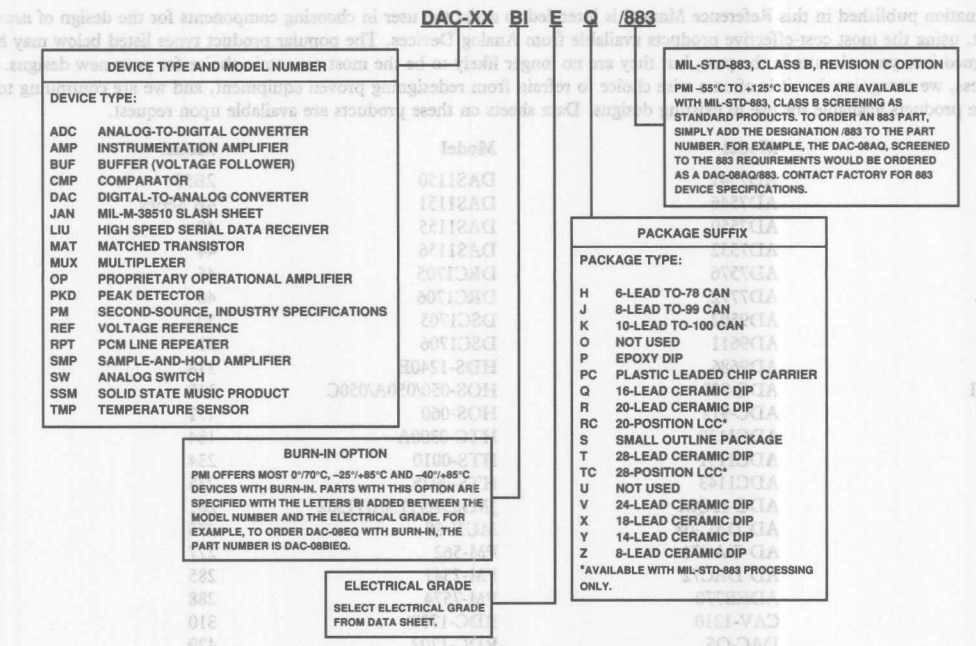

Figure 2. Precision Monolithics Division's Product Designations

ORDERING FROM ANALOG DEVICES

When placing an order, please provide specific information regarding model type, number, option designations, quantity, ship-to and bill-to address. Prices quoted are list; they do not include applicable taxes, customs, or shipping charges. All shipments are F.O.B. factory. Please specify if air shipment is required.

Place your orders with our local sales office or representative, or directly with our customer service group located in the Norwood facility. Orders and requests for quotations may be telephoned, sent via FAX or TELEX, or mailed. Orders will be acknowledged when received; billing and delivery information is included.

Payments for new accounts, where open-account credit has not yet been established, will be C.O.D. or prepaid. Analog Devices' minimum order value is two hundred fifty dollars ($250.00).

When prepaid, orders should include $2.50 additional for packaging and postage (and a 5% sales tax on the price of the goods if you are ordering for delivery to a destination in Massachusetts).

You may also order Analog Devices parts through distributors. For information on distributors, please see pages 12–12 and 12–13 at the back of this volume.

WARRANTY AND REPAIR CHARGE POLICIES

All Analog Devices, Inc., products are warranted against defects in workmanship and materials under normal use and service for one year from the date of their shipment by Analog Devices, Inc., except that components obtained from others are warranted only to the extent of the original manufacturers' warranties, if any, except for component test systems, which have a 180-day warranty, and μMAC and MACSYM systems, which have a 90-day warranty. This warranty does not extend to any products which have been subjected to misuse, neglect, accident, or improper installation or application, or which have been repaired or altered by others. Analog Devices' sole liability and the Purchaser's sole remedy under this warranty is limited to repairing or replacing defective products. (The repair or replacement of defective products does not extend the warranty period. This warranty does not apply to components which are normally consumed in operation or which have a normal life inherently shorter than one year.) Analog Devices, Inc., shall not be liable for consequential damages under any circumstances.

THE FOREGOING WARRANTY AND REMEDY ARE IN LIEU OF ALL OTHER REMEDIES AND ALL OTHER WARRANTIES, WRITTEN OR ORAL, STATUTORY, EXPRESS, OR IMPLIED, INCLUDING ANY WARRANTY OF MERCHANTABILITY OR FITNESS FOR A PARTICULAR PURPOSE.

Product Families Not Included in the Reference Manual (But Still Available)

The information published in this Reference Manual is intended to assist the user in choosing components for the design of *new* equipment, using the most cost-effective products available from Analog Devices. The popular product types listed below may have been designed into your circuits in the past, but they are no longer likely to be the most economic choice for your new designs. Nevertheless, we recognize that it is often a wise choice to refrain from redesigning proven equipment, and we are continuing to make these products available for use in existing designs. Data sheets on these products are available upon request.

Substitution Guide for Product Families No Longer Available

The products listed in the left-hand column are no longer available from Analog Devices. In many cases, comparable functions and performance may be obtained with newer models, but—as a rule—they are not directly interchangeable. The closest recommended Analog Devices equivalent, physically and electrically, is listed in the right-hand column. If no equivalent is listed, or for further information, contact your local sales office.

Technical Publications

Analog Devices provides a wide array of FREE technical publications. These include Data Sheets, Catalogs, Application Notes and Guides and four serial publications: *Analog Productlog*, a digest of new-production information; *DSPatch*™, a newsletter about digital signal-processing (applications); *Analog Briefings*®, current information about products for military/avionics and the status of reliability at ADI; and *Analog Dialogue*, our technical magazine, with in-depth discussions of products, technologies and applications.

In addition to the free publications, a group of technical reference books are available at reasonable cost. Subsystem products are supported with hardware, software, and user documentation, at prices related to content.

Brief descriptions of typical publications appear below. For copies of any items, to subscribe to any of our free serials or to request any other publications, please get in touch with Analog Devices or the nearest sales office.

CATALOGS

Data Acquisition Products Databooks. Contain selection guides, data sheets and other useful information about all Analog Devices ICs, hybrids, modules and subsystem components recommended for new designs. The current series consists of:

DATA CONVERTER REFERENCE MANUAL—1992: Volumes 1 and 2. Data sheets and selection guides on A/D and D/A Converters, V/F and F/V Converters, Synchro/Resolver-to-Digital Converters, Sample/Track-Hold Amplifiers, Switches and Multiplexers, Voltage References, Data-Acquisition Subsystems, Analog I/O Ports, Communications Products, Bus Interface and I/O Products, Application-Specific ICs, Digital Panel Meters, Power Supplies. (Available FREE)

LINEAR PRODUCTS DATABOOK—1990/1991. Data Sheets and Selection Guides on Op Amps, Instrumentation Amplifiers, Isolators, RMS-to-DC Converters, Multipliers/Dividers, Log/Antilog Amplifiers, Comparators, Temperature-Measuring Components and Transducers, Special Function Components, Digital Panel Instruments, Signal-Conditioning Components and Subsystems, Mass Storage Components, ATE Components, Automotive Components, Bus Interface and Serial I/O Products, Application Specific ICs. (Available FREE.)

AUDIO/VIDEO REFERENCE MANUAL—SSM Audio Products from ADI's PMI Division: VCAs, Surround-Sound Decoder, Audio Preamplifiers, Audio Switches, Line Driver/Receiver, Audio Op Amps, Matched Transistors, Level Detection System, Voltage-Controlled Filters, Log Conversion Amplifier, Multiplexed Sample/Hold, plus 19 Application Notes.

MILITARY PRODUCTS DATABOOK—1990 (in two volumes) Information and data on products available with processing in accordance with MIL-STD-883.

Volume 2: PMI Division products—including Class S
Volume 1: All other Analog Devices products

DATA-ACQUISITION AND CONTROL CATALOG—1990. Tutorial and Configuration Guide, with Product Reference and Index. Bus-Compatible I/O Boards for: IBM PS/2,* IBM PC/XT/AT,* STD Bus, VMEbus, MULTIBUS.† Distributed I/O Subsystems—fixed-function front ends, programmable units, and distributed control systems. Modular Signal Conditioners—analog and digitizing. Analog Signal-Conditioning Panels—isolated and nonisolated. Digital Subsystems—16- and 24/32-channel. Software—DOS drivers and applications packages.

POWER SUPPLIES‡–Linear Supplies•DC-DC Converters. 12-page Short-Form Catalog listing AC/DC Power Supplies, Modular DC/DC Converters, Power-Supply Test Procedures, Transients, Thermal Derating, Mechanical Outlines of Packages and Sockets.

APPLICATION NOTES

Available individually upon request:

A/D Converters

"AD671 12-Bit, 2-MHz ADC Digitizes CCD Outputs for Imaging Applications" [E1455]
"AD7672 Converter Delivers 12-Bit 200-kHz Sampling Systems" [E1313]
"Asynchronous Clock Interfacing with the AD7878" [E1334]
"Bipolar Operations with the AD7572" [E1010]
"Evaluation Board for the AD7701/AD7703 Sigma-Delta A/D Converters" [E1483]
"FIFO Operation and Boundary Conditions in the AD1332 and AD1334" [E1355]
"How to Obtain the Best Performance from the AD7572" [E1038]
"Implement Infinite Sample-and-Hold Circuits Using Analog Input/Output Ports" [E1359]
"Simple Circuit Provides Ratiometric Reference Levels for AD782X Family of Half-Flash ADCs" [E1412]
"Simultaneous and Independent Sampling of Analog Signals with the AD1334" [E1358]
"The AD7574 Analog-to-Microprocessor Interface" [E694]
"Using Multiple AD1334s in Many-Channel Synchronous Sampling Applications" [E1435]

Amplifiers

"A Balanced-Input High-Level Amplifier" [AN-112]
"Active Feedback Improves Amplifier Phase Accuracy" [AN-107]
"AD9617/AD9618 Current-Feedback Amplifier Macro-Models" [E1460]
"An IC Amplifier User's Guide to Decoupling, Grounding, and Making Things Go Right for a Change" [AN-202]
"An Ultralow-Noise Preamplifier" [AN-136]
"An Unbalanced Virtual-Ground Summing Amplifier" [AN-113]
"Applications of High-Performance BiFET Op Amps" [E727]
"CMOS DACs and Operational Amplifiers Combine to Build Programmable-Gain Amplifiers" (in 2 parts: I and II) [E1073A and E1110]

†MULTIBUS is a trademark of Intel Corporation.
‡This publication is available in North America only.

"How to Test Basic Operational Amplifier Parameters" [AN-201]
"JFET-Input Amps Are Unrivalled for Speed and Accuracy" [AN-108]
"Low-Cost Two-Chip Voltage-Controlled Amplifier and Video Switch" (AD539) [AN-213]
"Using the AD9610 Transimpedance Amplifier" [E1097]
"Very Low-Noise Operational Amplifier" (OP-27) [AN-102]

Analog Signal-Processing and Measurement
"A Function Generator and Linearization Circuit Using the AD7569" [E1369]
"Precision Surface Measurements Using the AD2S58" [E1486]
"RMS-to-DC Converters Ease Measurement Tasks" [E1519]
"Understanding and Applying the AD7341/AD7371 Switched-Capacitor Filters" [E1373]

Audio
"A Balanced Mute Circuit for Audio Mixing Consoles" [AN-122]
"A Constant-Power 'Pan' Control Circuit for Microphone Audio Mixing" [AN-123]
"A High-Performance Compandor for Wireless Audio Systems" [AN-133]
"An Automatic Microphone Mixer" [AN-134]
"An Ultralow Noise Preamplifier" [AN-136]
"A Precision Sum and Difference (Audio Matrix) Circuit" [AN-129]
"A Two-Band Audio Compressor/Limiter" [AN-130]
"A Two-Channel Dynamic Filter Noise Reduction System" [AN-125]
"High Performance Stereo Routing Switcher" [AN-121]
"Interfacing Two 16-Bit AD1856 (AD1851) Audio DACs with the Philips SAA7220 Digital Filter" [AN-207]
"Three High-Accuracy RIAA/IEC MC and MM Phono Preamplifiers" [AN-124]

D/A Converters
"AD7528 Dual 8-Bit CMOS DAC" [E757]
"Analog Panning Circuits Provide Almost Constant Output Power" [AN-206]
"Circuit Applications of the AD7226 Quad CMOS DAC" [E873]
"CMOS DACs and Operational Amplifiers Combine to Build Programmable-Gain Amplifiers" (in 2 parts: I and II) [E1073A and E1110]
"Dynamic Performance of CMOS DACs in Modem Applications" [E1172]
"8th Order Programmable Low-Pass Filter Using Dual 12-Bit DACs" [AN-209]
"Exploring the AD667 12-Bit Analog Output Port" [E875]
"14-Bit DACs Maintain High Performance Over Extended Temperature Range" [E987]
"Gain Error and Tempco of CMOS Multiplying DACs" *[E630C]*
"Generate 4 Channels of Analog Output Using AD7542 12-Bit D/A Converters and Control the Lot with Only Two Wires" [E909]
"Interfacing the AD7549 Dual 12-Bit DAC to the MCS-48 and MCS-51 Microcomputer Families" [E941]
"Replacing the AD1145 with the AD7846" [E1467]
"Simple Interface Between D/A Converter and Microcomputer Leads to Programmable Sine-Wave Oscillator" (AD7542) [E889]
"The AD7224 DAC Provides Programmable Voltages Over Varying Ranges" [E910]
"Three-Phase Sine-Wave Generation Using the AD7226 Quad DAC" [E924]
"Understanding and Preventing Latchup in CMOS DACs" [AN-109]
"Voltage Adjustment Applications of the DAC-8800 TrimDAC™, an Octal 8-Bit D/A Converter" [AN-142]

Digital Signal-Processing
"Considerations for Selecting a DSP Processor" (ADSP-2100A vs. TMS320C25) [E1306]
"Considerations for Selecting a DSP Processor" (ADSP-2101 vs. WE DSP16A) [E1446]
"Considerations for Selecting a DSP Processor" (ADSP-2101 vs. TMS320C50) [E1558]
"Implement a Cache Memory in Your Word-Slice® System" [E1062]
"Sharing the Output Bus of the ADSP-1401 Microprogram Sequencer" [E1059]
"Using Digitally Programmable Delay Generators" [E1518a]
"Variable-Width Bit Reversing with the ADSP-1410 Address Generator" [E1061]

Disk-Drive Electronics
"Microstepping Drive Circuits for Single Supply Systems" [E1229A]
"Simple DAC-Based Circuit Implements Constant Linear Velocity (CLV) Motor Speed Control" [E1236]

Modelling
"AD9617/AD9618 Current-Feedback Amplifier Macro-Models" [E1460]
"OP-42 Advanced SPICE Macro-Model" [AN-117]
"OP-64 Advanced SPICE Macro-Model" [AN-110]
"OP-260 Advanced SPICE Macro-Model" [AN-126]
"OP-400 SPICE Macro-Model" [AN-120]
"OP-470 SPICE Macro-Model" [AN-132]
"SPICE-Compatible Op Amp Macro-Models" [AN-138]

Power Supply
"A Low-Voltage Power Supply Watchdog Monitor Circuit" [AN-139]

Practice
"An IC Amplifier User's Guide to Decoupling, Grounding, and Making Things Go Right for a Change" [AN-202]
"How to Reliably Protect CMOS Circuits Against Power-Supply Overranging" [C1499]

Repeater Circuits
"Improved T148 (CEPT) PCM Repeater for #22AWG (0.7mm) Unshielded Twisted-Pair Wire" [AN-119]

Resolver (Synchro) to Digital Conversion
"Circuit Applications of the 2S81 and 2S80 Resolver-to-Digital Converters" [E1140]

"Dynamic Characteristics of Tracking Converters" [E1141]
"Dynamic Resolution-Switching on the 1S74 Resolver-to-Digital Converter" [E919]
"Using the 2S80 Series Resolver-to-Digital Converters with Synchros: Solid-State Scott-T Circuit" [E1361]
"Why the Velocity Output of the 1S74 and 1S64 Series R/D Converters is Continuous and Step-Free Down to Zero Speed" [E893]

Sample-Holds
"Applying IC Sample-Hold Amplifiers" [E931]
"Generate 4 Channels of Analog Output Using AD7542 12-Bit D/A Converters and Control It All with Only Two Wires" [E909]
"Implement Infinite Sample-and-Hold Circuits Using Analog Input/Output Ports" [E1359]

Switches and Multiplexers
"ADG201A/202A and ADG221/222 Performance with Reduced Power Supplies" [E1052]
"Bandwidth, OFF Isolation, and Crosstalk Performance of the ADG5XXAA Multiplexer Series" [E1340]
"Overvoltage Protection for the ADG5XXA Multiplexer Series" [E1237]
"R_{ON} Modulation in CMOS Switches and Multiplexers; What it Is and How to Predict its Effect on Signal Distortion" [E1470]

Temperature Measurement
"A Cost-Effective Approach to Thermocouple Interfacing in Industrial Systems" [E730]
"Use of the AD590 Temperature Sensor in a Remote Sensing Application" [E920]

V/F Converters
"Analog-to-Digital Conversion Using Voltage-to-Frequency Converters" [E994A]
"Operation and Applications of the AD654 IC V-to-F Converter" [E923]
"Using the AD650 Voltage-to-Frequency Converter as a Frequency-to-Voltage Converter" [E1539]

Video Applications
"Animation Using the Pixel Read Mask Register of the ADV47X Series of Video RAM-DACs" [E1316]
"Changing Your VGA Design from a 171/176 to an ADV471" [E1260]
"Design and Layout of a Video Graphics System for Reduced EMI" [E1309]
"Improved PCB Layouts for Video RAM-DACs Can Use Either PLCC or DIP Package Types" [E1225]
"Low Cost Two-Chip Voltage-Controlled Amplifier and Video Switch." (AD539) [AN-213]
"The AD9502 Video Signal Digitizer and Its Applications" [E1173]
"Video Formats & Required Load Terminations." [AN-205]

APPLICATION GUIDES

Analog CMOS Switches and Multiplexers. A 16-page short-form guide to high-speed CMOS switches, CMOS switches with dielectric isolation and CMOS multiplexers. Also included are reliability data and information on single-supply operation.

Applications Guide for Isolation Amplifiers and Signal Conditioners. A 20-page guide to specifications and applications of galvanically isolated amplifiers and signal conditioners for industrial, instrumentation and medical applications.

CMOS DAC Application Guide 3rd Edition by Phil Burton (1989—64 pages). Introduction to CMOS DACs, Inside CMOS DACs, Basic Application Circuits in Current-Steering Mode, Single-Supply Operation Using Voltage-Switching Mode, The Logic Interface, Applications.

ESD Prevention Manual – Protecting ICs from electrostatic discharges. Thirty pages of information that will assist the reader in implementing an appropriate and effective program to assure protection against electrostatic discharge (ESD) failures.

High-Speed Data Conversion – A 24-page short-form guide to video and other high-speed A/D and D/A converters and accessories, in forms ranging from monolithic ICs to card-level products.

RMS-to-DC Conversion Application Guide 2nd Edition by C. Kitchin and L. Counts (1986—61 pages). RMS-DC Conversion: Theory, Basic Design Considerations; RMS Application Circuits; Testing Critical Parameters; Input Buffer Amplifier Requirements; Programs for Computing Errors, Ripple and Settling Time.

Surface Mount IC‡—A 28-page guide to ICs in SO and PLCC packages. Products include op amps, rms-to-dc converters, DACs, ADCs, VFCs, sample-holds and CMOS switches.

DIGITAL SIGNAL PROCESSING MANUALS

Available at no charge for single copies; write on letterhead.

ADSP-2101/ADSP-2102 USER'S MANUAL—Architecture. [Fixed-point processor] Introduction; Computational Units; Data Moves, Program Control; Timer; Serial Ports; System Interface; Memory Interface; Instruction Set Overview; Appendixes; Index. 190 pages.

ADSP-2111 USER'S MANUAL—Architecture. [Fixed-point processor] Introduction; Computational Units; Data Moves; Program Control; Timer; Host Interface Port; Serial Ports; System Interface; Memory Interface; Instruction Set Overview; Appendixes; Index. 218 pages.

ADSP-21020 USER'S MANUAL. [Floating-point processor] Introduction; Computational Units; Program Sequencing; Data Addressing; Timer; Memory Interface; Instruction Summary; Assembly Programmer's Tutorial; Hardware System Configuration; Appendixes; Index. 394 pages.

TECHNICAL REFERENCE BOOKS

Can be purchased from Analog Devices, Inc., at the prices shown. If more than one book is ordered, deduct a discount of $1.00 from the price of each book. Price of the entire set of 9 books is $166.00—a bargain for your department's library (in effect, the nonlinear, transducer, and high-speed books come free). VISA and MasterCard are welcome; phone (617) 461-3392 or FAX (617)821-4273. Or send your check for the indicated amount to Analog Devices, Inc., P.O. Box 9106, Norwood, MA 02062-9106.

‡This publication is available in North America only.

ANALOG-DIGITAL CONVERSION HANDBOOK: Third Edition, by the Engineering Staff of Analog Devices, edited by Daniel H. Sheingold. Englewood Cliffs, NJ: Prentice Hall (1986). A comprehensive guide to A/D and D/A converters and their applications. This third edition of our classic is in hardcover and has more than 700 pages, an Index, a Bibliography, and much new material, including: video-speed, synchro-resolver, V/F, high-resolution, and logarithmic converters, ICs for DSP, and a "Guide for the Troubled." Seven of its 22 chapters are totally new. $32.95

DIGITAL SIGNAL-PROCESSING APPLICATIONS USING THE ADSP-2100 FAMILY, by the Applications Staff of Analog Devices, DSP Division; edited by Amy Mar (628 pages). Englewood Cliffs NJ: Prentice Hall (1990). Bridge the gap between DSP algorithms and their real-world implementation on state-of-the-art signal processors. Each chapter tackles a specific application topic, briefly describing the algorithm and discussing its implementation on the ADSP-2100 family of DSP chips. Comprehensive source-code listings are complete with comments and accompanied by explanatory text. Programs are listed on a pair of supplementary diskettes—furnished with the book. Application areas include fixed- and floating-point arithmetic, function approximation, digital filters, one- and two-dimensional FFTs, image processing, graphics, LP speech coding, PCM, ADPCM, high-speed modem algorithms, DTMF coding, sonar beamforming. Additional topics include memory interface, multiprocessing, and host interface. The book can serve as a companion to *Digital Signal Processing in VLSI*. Price includes diskettes. $38.00

DIGITAL SIGNAL PROCESSING IN VLSI, by Richard J. Higgins. Englewood Cliffs NJ: Prentice Hall (1990). An introductory 614-page guide for the engineer and scientist who needs to understand and use DSP algorithms and special-purpose DSP hardware ICs—and the software tools developed to carry them out efficiently. Real-World Signal Processing; Sampled Signals and Systems; The DFT and the FFT Algorithm; Digital Filters; The Bridge to VLSI; Real DSP Hardware; Software Development for the DSP System; DSP Applications; plus Bibliography and Index. $38.00

NEW—*DIGITAL SIGNAL PROCESSING LABORATORY Using the ADSP-2101 Microcomputer*, by Vinay K. Ingle and John G. Proakis (Northeastern University). Englewood Cliffs NJ: Prentice Hall (1991). Contents: Introduction to the ADSP-2100/2101 family; ADSP-2101 instruction set overview; Overview of development tools; Getting started with the ADSP-2101; Laboratory experiments using the ADSP-2101; FIR filter implementation; IIR filter implementation; Fast Fourier transform implementation; Applications in communications; Adaptive filters and their applications; References; Index. $24.00

HIGH-SPEED DESIGN SEMINAR, published by Analog Devices (1990). A 496-page guide to the practical application of high-speed semiconductor devices in processing of analog signals. Topics include: data conversion, digital video applications, high-speed sample-holds and operational amplifiers, nonlinear signal processors (including log amps), comparators and pin electronics, time-delay generators, phase-locked loops, direct digital synthesis, computer graphics and RAMDACs, and high-speed techniques. $20.00

NEW—*MIXED-SIGNAL DESIGN SEMINAR*, published by Analog Devices (1991). Contents: Introduction to mixed-signal processing of real-world signals and signal conditioning; Linear and nonlinear analog signal processing; Fundamentals of sampled-data systems; ADCs for DSP applications; DACs for DSP applications; Sigma-delta ADCs and DACs; Digital signal-processing techniques; DSP hardware; Interfacing ADCs and DACs to digital signal processors; Mixed-signal processing applications; Mixed-signal circuit techniques; Index. $22.00

NONLINEAR CIRCUITS HANDBOOK: Designing with Analog Function Modules and ICs, by the Engineering Staff of Analog Devices, edited by Daniel H. Sheingold. Norwood MA: Analog Devices, Inc. (1974). A 540-page guide to multiplying and dividing, squaring and rooting, rms-to-dc conversion, and multifunction devices. Principles, circuitry, performance, specifications, testing, and application of these devices–contains 325 illustrations. $5.95

SYNCHRO & RESOLVER CONVERSION, edited by Geoff Boyes. Norwood, MA; Analog Devices, Inc. (1980). Principles and practice of interfacing synchros, resolvers, and Inductosyns* to digital and analog circuitry. $11.50

TRANSDUCER INTERFACING HANDBOOK: A Guide to Analog Signal Conditioning, edited by Daniel H. Sheingold. Norwood MA: Analog Devices, Inc. (1980). A book for the electronic engineer who must interface transducers for temperature, pressure, force, level, or flow to electronics, these 260 pages tell how transducers work—as circuit elements—and how to connect them to electronic circuits for effective processing of their signals. $14.50

***Inductosyn is a registered trademark of Farrand Industries, Inc.**
